WE find many examples in stories, which very directly and mightily doe testifie against *M. Varro*, as touching Papers. For *Cassius Hemina* (a most faithfull and auncient writer) in the fourth book of his Annales, hath reported, That one *Cn. Terentius* a scribe or publick Notarie, as he digged and delved in a ground which he had neare to Ianiculum, light upon a chist, wherein lay the bodie of *Numa*, sometime king of Rome. In the same also were found the bookes of the said king. And (as he affirmeth) this happened in that yeare, when *Pub. Cornelius* the sonne of *Lucius*, surnamed *Cethegus*, and *M. Bœbius* sonne of *Quintus*, surnamed *Pamphilus*, were Consuls of Rome: betweene which time and the raigne of *Numa*, by just computation are reckoned 535 yeeres. He saith moreover, That those books were made of the Paper abovenamed. The greater wonder it was, how such kind of bookes should last so long, especially within the earth, and not putrifie? The thing therefore being so strange, and in manner miraculous, that Paper should continue all that time, I thinke it not amisse to set downe the very words of *Hemina* himselfe, as he delivereth them. The world made a wonder (quoth he) how those books could possibly endure so many yeares? but the partie who found them yeelded this reason: That within the said coffer about the middest of it, there was a stone foure-square, lapped all about and bound every way with [waxe] candles in manner of a serecloth: upon which stone, the foresaid books were laid: and therfore it was (as he supposed) that they did not rot. Moreover, the books also were embaulmed with the rosin or oile of Cedar, which might be a good reason in his conceit, that the moths came not to them. Now these books contained the Philosophie and doctrine of *Pythagoras*: and for that they treated of that Philosophicall argument, burnt they were, by order from *Q. Petilius* the Pretour for that time being. The same storie in effect doth *C. Piso Censorinus* (a man who had been Censor) report in the first booke of his Commentaries: howbeit, he setteth downe their number withall: and saith they were foureteene in all, whereof seven treated of the Pontificall law, and matters of religion; and as many discoursed of *Pythagoras* his Philosophie. But *Tuditanus* in the thirteenth booke of the Annales affirmeth, That they were the decretals onely of *Numa*, and contained his ordinances. As for *Varro* himselfe, he writeth in the fift booke of Humane Antiquities, that they were in all but twelve. And *Antias* in his second booke reporteth, That two of them were written in Latine, and contained the Pontificiall divinitie and church-matters: and other twaine penned in Greeke, were full of precepts in Philosophie. He also affirmeth in his third booke, for what cause the said bookes by vertue of a publicke decree were consumed with fire. But all Historiographers agree in this, That one of the *Sibyls* brought unto *Tarquinius* the prowd three books: of which, two were burnt by her own selfe: and the third likewise perished with fire, together with the Capitoll, during the troubles of *Silla*. Over and besides, *Mutianus*, a man who had ben thrice Consull of Rome, hath left upon record, that of late, while he was lord governour of Lycia, hee red in a certaine temple an Epistle written by prince *Sarpedon* in Paper, and bearing date from Troy. And I wonder the rather at this, if so be that when *Homer* lived and wrate his Poëme, there was no land of Ægypt as now there is: or why, in case there was such use of Paper then, himselfe should write, that in the very same Lycia, *Bellerophon* had writing tables given him to deliver as touching his owne death, and not rather letters missive written in Paper? Well, howsoever that bee, this is certaine, that there is a scarsitie otherwhiles of Paper also, as well as of other commodities: and this cane or reed Papyrus doth many times faile. For not long since, even in the daies of *Tiberius* the Emperor, in a dearth and want of Paper, there were commissioners deputed and appointed by the Senate of Rome, for the dispensing and distribution of it among the people: otherwise there had been a great mutinie and tumult at Rome about Paper.

*L. Petilius. Livie.

Chap.

Chap. xiiii.

Of the trees in Æthiopia.

AS touching Æthiopia, and namely that quarter which confineth upon Ægypt, it hath in manner no trees at all of any name, ſave thoſe that beare woollor cotton: concerning the nature of which trees, we have ſufficiently ſpoken in the deſcription of the Indians, and of Arabia: and yet in very truth, the cotton that is brought from theſe trees in Æthiopia, commeth nearer to wooll than any thing els; howſoever the trees be otherwiſe like to the reſt of that kind: and the burſe or cod wherein this woollie ſubſtance lyeth, is greater, and as big as a Pomegranat. Beſides theſe, there be Date trees alſo, like to ſuch as we have before deſcribed. As touching other trees, and eſpecially the odoriferous woods within the Iſles that lie upon Æthiopia round about, we have ſaid enough in the treatiſe of thoſe Ilands.

Chap. xv.

Of the Trees growing in mount Atlas: of Citron tables: of the commendable perfections, and contrariwiſe of the defaults thereof.

THE mountaine Atlas (by report) hath a wood in it of peculiar trees that elſewhere grow not, wherof we have alreadie written. The Mores that border upon it, are ſtored with abundance of Citron trees: from whence commeth that exceſſive expenſe and ſuperfluitie about Citron tables made thereof. And our dames and wives at home (by way of revenge) uſe to twit us their husbands therewith, when we would ſeeme to find fault with the coſtly pearls that they doe weare. There is at this day to be ſeene a board of Citron wood, belonging ſometimes to *M. Tullius Cicero*, which coſt him ten thouſand Seſterces: a ſtraunge matter, conſidering he was no rich man: but more wonderfull, if wee call to mind the ſeveritie of that age wherein hee lived. Much ſpeech there is beſides of *Gallus Aſinius* his table, ſold for eleven thouſand Seſterces. Moreover, there are two other, which K. *Iuba* ſold: the one was priſed at 15000 Seſterces, and the other held little under. Not long ſince, there was one of them chaunced to be burnt, and it came with other houſhold ſtuffe but from the cottages in Mauritania, which coſt 140000 Seſterces: a good round ſumme of money, and the price of a faire lordſhip, if a man would be at the coſt to purchaſe lands ſo deare. But the faireſt and largeſt table of Citron wood, that to this day hath beene ſeene, came from *Ptolomæe* king of Mauritania, the which was made of two demie-rounds or halfe circles, joyned togither ſo artificially, that for the cloſeneſſe of the joynt (which could not be diſcerned) it was more admirable than poſſibly it could have beene if it had beene naturally of one entire peece: the diameter of it caried foure foot and a halfe, and three inches thicke it was. Likewiſe another ſuch table there was, ſurnamed Nomien, of one *Nomius* a ſlave, enfranchiſed by *Tyberius* the Emperour: the ſquare or diametre whereof, was foure foot within three quarters of an inch; and the thicknes halfe a foot lacking ſo much. And here I cannot forget and overpaſſe, how that the Emperour *Tyberius* himſelfe had a table, which being two inches & three quarters above four foot in the diametre, & an inch and an halfe thick throughout, he cauſed to be plated all over, for that *Nomius* his freed ſervant had one ſo rich and magnificent, made altogither of a knot: a knot (I ſay) or a knur in the root of the tree, which is the very beautie of the wood, and giveth all the grace to the tables made therof; and namely, if this knot lie altogither within ground, it is without compariſon excellent, and farre more rare and ſingular than any of the timber above, either in the trunke and bodie, or in the armes and boughes of the tree. So that (to ſay a truth) this coſtly ware bought ſo deare, is no better than the ſuperfluous excreſcenſe of trees: the largeneſſe whereof, as alſo of their roots, may be eſteemed by the roundnes that they carrie. Now are theſe Citron trees much like to the female Cypreſſe (eſpecially that of the wild kind) in leafe, in ſmell, and in bodie. A mountaine there is in high Mauritania, called Anchorarius, which was wont to yeeld the beſt and faireſt Citron trees, although now it be naked and deſpoiled of them. But to return to our tables aforeſaid; the principall be they which are either criſped in the length of the veine, or beſet here and there with winding ſpots. In the former, the wood curleth in and out along the graine; and therefore ſuch be named Tigrinæ, [*i.* Tigre-tables.] In the other, there be repreſented ſundrie tufts as it were enfolded

folded and enwrapped round, and thoſe they call Pantherinæ, [i. Panther, or Luzerne tables.] There be againe, whereof the worke in waineſcot reſembleth the waves of the ſea: and the better grace they have, and bee more eſteemed, if they make a ſhew of the eies appearing in Peacockes tailes. Next in requeſt and account to theſe abovenamed, bee thoſe that are friſled with ſmall ſpots ſtanding thicke, as if many graines were gathered together, which they call thereupon (of ſome reſemblance of litle bees or flies) Apiatæ, as if they were ſpeckled and filed with their dung. But be the worke and grain of the wood what it will, the colour maketh all. Here at Rome wee ſet moſt ſtore by that colour which is like to mead or honied wine, ſhining and glittering in the veines of the wood. After which conſiderations, men regard much the breadth and largenes of the whole plant, ſtanding of one entire peece which maketh the table. Some take a great pleaſure to ſee in one Citron bourd many of thoſe faults which bee incident to trees, to wit, the Lignum, for ſo they call the ſimple, plaine, and bare wood and timber without any branched or curled graine at all, without a ſhining luſtre and glittering gloſſe, without worke to be ſeene in any order digeſted, or at the moſt (if any bee) repreſenting the leaves of a Plane tree. Againe, the reſemblance either of the veine or colour of a kind of Oke wood called Ilex. Moreover, the rifts and chinkes which timber is ſubject unto, by reaſon principally of wind and Sunnes heat: or elſe hairie ſtreakes that be like to ſuch clifts and creviſſes. Afterwards men were delighted with a kind of Lamprey veine traverſing and running over a blacke croſſe way: and with an outward skin or coat marked with ſpeckes or knottie knurs, like to Poppie heads: and generally with a colour all over, comming neare to blacke, or at leaſtwiſe beſpotted with ſundrie colours. The Barbarians for to ſeaſon the wood of this Citron tree, uſe to burie the greene bourds or plankes thereof within the ground, and beſmeare them all over with waxe. But the artificers and workemen doe put them for ſeven daies within heapes of corne, and ſtay ſeven daies more ere they be wrought: and a wonder it is incredible, how much of the weight the wood loſeth by this meanes. Moreover, of late daies wee have found the experience by ſhipwrackes, that this timber alſo will by nothing in the world be ſooner dried nor hardened to laſt a long time without corruption, than by ſea water. Howbeit, to maintaine theſe tables beſt, and to cauſe them for to ſhine bright, the way is to rub them with a drie hand, eſpecially after that a man is newly come out of the baines or hot houſe. Neither catch they any harme or ſtaine, if wine bee ſpilt thereupon: ſo as it ſhould ſeeme they were naturally made for wine. To conclude, a tree this is ſerving for the ornaments of this life, and the trim furniture of our houſe, few or none like to it: and therfore me thinks I do not amiſſe to continue the diſcourſe thereof ſomewhat longer than ordinarie.

Chap. xvi.

Of the tree Thya, what it is.

WEll knowne unto *Homer* was this Tree, which in Greeke is named * Θύον, but ſome call it Thya: for among other daintie odors and ſweet woods, he reporteth, That dame *Circe* (whome he would have to be reputed as a goddeſſe) burnt of this Thyon. And therefore much deceived are they, who underſtand by that word Thyon, perfumes and odoriferous ſpice, conſidering that in one and the very ſame verſe, the Poët maketh mention of the Cedar and Larch tree togither with Thyon, whereby it appeareth plaine, that he ſpake of trees only. *Theophraſtus*, who after the daies of *Alexander* the Great, was the firſt that wrate the hiſtory of thoſe acts which happened about the 440 yeere from the foundation of Rome, gave great honour even then to this Tree, and reported, That all carpenters worke of temples in old time, was made of the ſame; as of a timber everlaſting, and which in roufes would continue without all putrefaction and corruption whatſoever. Moreover, he writeth, That the wood of the root is ſo curled and friſled, as none more; and that of no timber beſides are more curious peeces of workes made, nor of greater price. Over and beſides, he ſaith, That the faireſt and goodlieſt trees of this kind, doe grow about the temple of *Iupiter Hammon*: and ſome of them alſo within the countrey Cyrenaica toward the inland parts. But all this while not a word of the foreſaid coſtly tables ſpeaketh he in his whole hiſtorie: and verily before that of *Ciceroes*, there is no record in writers of any ſuch tables: whereby it appeareth, that they be come up but of late daies. Another tree there is likewiſe of that name, bearing an apple or fruit, which ſome cannot abide for the ſtrong ſavour and bitternes withall, others againe like and love it as well. This tree alſo beautifieth and ſetteth out the houſe, but I purpoſe not to beſtow many words more thereof.

Chap.

Chap. xvii.

Of the tree Lotus.

IN the ſame coaſt of Affrick which regardeth Italie, there groweth Lotos, which they call Celtis. A notable tree it is and of ſpeciall marke: found alſo here among us now in Italy, but togither with the ſoile, it hath chaunged the nature. The faireſt and goodlieſt of them be about the Syrtes and the Naſamones: they be as big and tall as Peare trees, howſoever *Nepos Cornelius* ſaith, they are but little and low. The leaves bee thicke cut and endented: otherwiſe they were like to thoſe of the Ilex or Holme tree. Many ſorts there be of the Lote tree, and thoſe for the moſt part according to their divers and ſeverall fruits. Howbeit ordinarily the fruit is as big as a Beane, and of yellow colour as Saffron; yet before it is full ripe, it chaungeth into ſundry colors, like as grapes doe. It groweth thicke among the branches of the tree, in manner of Myrtle berries, and not like to the cherries of Italie: and in thoſe plants above named, the meat thereof is ſo ſweet and pleaſant, that it hath given the name both to a nation and a countrey, inſomuch as the people be called Lotophagi: and withall, ſo welcome be all ſtraungers thither, and ſo well contented with their entertainment, that they forget their own native ſoile, for the love they have to this fruit, when they have once taken to it. By report, whoſoever eateth thereof, is free from the diſeaſes of the bellie. This fruit is counted the better, which hath no kernell within; for there is another kind wherein the ſaid kernell ſeemeth as hard as a bone. Moreover, out of this fruit there is preſſed a wine like to Mede, which the above-named *Nepos* ſaith, will not laſt above ten daies: who reporteth beſides, That the inhabitants doe ſtampe the berries thereof with wheat or frumentie into a paſt, and ſo put it up in great barrels and ſuch like veſſels for the proviſion of their food. Moreover, we have heard ſay, that whole armies paſſing too and fro through Affrick, have fed thereof, and had no other meat: the wood is blacke of colour, and much ſought for it is to make Pipes and Fifes: of the root thereof, the hafts of daggers and knives be made, beſides other pretie deviſes of ſmall uſe. Thus much as touching the nature of the Lote ttee in thoſe parts: for there is an hearb alſo of that name [called Melilote.] As for the Ægyptian Lotus it is a plant bearing a ſtalke, and groweth in the mariſhes of Ægypt. For when the waters of Nilus are falne, which drenched the countrey, this plant commeth up in the flat & waterie levell along the river, with a ſtemme like unto the [Ægyptian] Beane, with leaves thruſt cloſe and thicke togither, howbeit ſhorter and leſſe than thoſe of the Beane: in the top of which ſtalke, it beareth fruit in manner of an head, for cuts and chamfres and every thing elſe like to thoſe of the Poppie: within which, there be conteined certaine graines or ſeeds reſembling Millet. The inhabitants of that countrey doe pile togither in heapes, thoſe heads, and ſo let them putrifie: afterwards, they ſeparate them, waſh them faire, and when they be drie, ſtampe and mould them, and thereof make their bread. A ſtraunge and wonderfull thing it is that is reported beſides; namely, That when the Sunne goeth downe, thoſe heads cloſe up and be covered with leaves, and remaine ſhut untill the morning; at what time they open againe: and thus continue this courſe untill they be ripe, and that the flower which is white, doth fall of it ſelfe.

Chap. xviii.

Of the very ſtalke, ſcape or ſtemme, and root of Lotus.

IT is ſaid moreover as touching this Ægyptian Lotus, that in Euphrates the very head of the ſtalke together with the flower, uſeth in the evening to be plunged and drowned under the water untill midnight, and ſo deepe to ſettle toward the bottome, that a man with his hand cannot reach thereto, nor find any part of it: but after that time, it beginneth to riſe by little and little, and by Sun-riſing appeareth above water, and openeth the flower, & ſtill mounteth higher and higher a good height from the water. This Lotos hath a root as bigge as a Quince, covered with a blacke rind or barke, much like to the huske of a Cheſtnut. The ſubſtance within, is white and delectable to eat, but more pleaſant beeing either ſodden in water, or roſted under embres, than raw: and Hogs will feed fat with nothing better, than with the pills and parings of this root.

Chap. xix.

Of Paliurus, the Pomegranate, and the flower of the Pomegranate.

THe region Cyrenaica in Affricke, maketh more account of their Paliurus than of Lotus: for the Paliurus ſhooteth forth more twigs and braunches, and hath a redder fruit than the Lotus. Beſides, the fruit and the kernell be eaten apart: and in truth, pleaſant it is of it ſelfe alone, but more pleaſant with wine; yea and the juice thereof giveth a better taſt to wine, if it be put into it. The inland parts of Affricke (as farre as to the Garamants and the deſerts) bee well planted with Date trees faire and great, bearing goodly and pleaſant Dates, and thoſe eſpecially in that quarter of Barbarie which lieth about the temple of *Iupiter Hammon*. But the territorie of Carthage challengeth to it ſelfe the Punicke apple: ſome call it the Pomegranat: and they have made ſeverall kindes thereof, calling that Apyrinon, which hath no woodie or hard kernell within: and indeed, theſe Pomegranats are naturally more white, the graines within more pleaſant, and divided with membranes and pellicles betweene, nothing ſo bitter as the other: for in both ſorts they bee framed and faſhioned within, like to honey-combes. As for thoſe Pomegranates which have ſuch kernels or ſtones, there bee five kinds of them, to wit, ſweete, ſower, temperate betweene both, ſtypticke or auſtere, and taſting of wine. But the Pomegranats of Samos and Ægypt, have this difference one from another, That ſome have red flowers on the head, and be therefore called Erythrocoma: others are white, and ſuch they name Leucocoma. The rind of ſower Pomegranats, is better for tanners and curriours to dreſſe their leather with, than of the reſt. The flower is called Balauſtium, both medicinable and alſo good for to die cloth; and hereof commeth the colour Puniceus [*i.* a light red or a bay] taking the name of the apple Punicke or Pomegranate.

Chap. xx.

Of the Shrubs in Aſia and Greece.

IN Aſia and Greece there grow certaine ſhrubs, to wit, Epipactis, which ſome call Elleborine, with ſmall leaves, which being taken in drinke are good againſt poiſon, like as the leaves alſo of *Erice withſtand the ſtinging of ſerpents.

* i. Heath, or Lings.

Chap. xxi.

Of Thymelæa or Chamelæa, Tragacanth, of Tragium or Scorpio. Alſo of Myrice, Brya, and Galla.

THe ſhrub or buſh which beareth the graine Gnidium, that ſome call Linum, is after ſome writers named Thymelæa, according to others Chamelæa: there bee that call it Pyrosachne: ſome againe give it the name of Cneſton, others of Cneoros. This plant howſoever it be named, reſembleth the wild olive, but that the leaves be narrower and gummie to the teeth, if a man bite them: for height and bignes anſwerable to the Myrtle: the ſeed thereof is for colour and faſhion, like to the graine of wheat, and ſerveth onely for Phyſicke.

As touching the plant Tragium, it is to be found in the Iland Candie only. It hath a reſemblance of the Terebinth, like as the ſeed alſo, which (by report) is moſt excellent and effectuall to heale wounds made by darts or arrowes. The ſame Iland hath the buſh Tragacanth growing in it, the root whereof is like to that of Bedegnar: and the ſame Tragacanth is much preferred before that which groweth either in Media or Achaia. A pound of Tragacanth is worth thirteen deniers Romane. As for the plant Tragium or Scorpio, it groweth likewiſe in Aſia. A kind of bramble or brier it is without any leaves, bearing fruit of berries much like to red grapes, wherof there is good uſe in Phyſicke.

Touching Myrice, which others call Tamarix; and Achaia Brya the wild; Italie bringeth it forth: this ſpeciall propertie it hath, that the tame kind therof only, namely that which groweth in gardens, beareth a fruit like the galls. In Syria & Ægypt this groweth plenteouſly, & the wood thereof we call Vnhappie: but the more unluckie & unfortunate be thoſe of Greece: for there groweth Oſtrys, named alſo Oſtrya, a ſolitarie tree about waterie and moiſt rocks, having barke

and

A and braunches like to the Ash, but Peare-tree leaves, save that they be somewhat longer & thicker, with long cuts or lines wrinkled and riveled throughout: and the seed in forme and colour is like to barley. The wood of it is hard and strong: and some say if any peece therof be brought into an house where a woman is in travaile of child-birth, shee shall have difficult labour, and hardly be delivered: and whosoever lyeth sicke there, shall die a miserable death.

Chap. xxii.

Of Euonymus or the Spindle tree of Adrachne, Congygria, and Thapsia.

B IN the Iland Lesbos, there groweth a tree named Euonymos, no better nor more luckie than Ostrya beforesaid. Much unlike it is not to the Pomegranate tree. As for the leafe that it beareth, it is of a middle size betweene that of the Pomegranat and the Bay; otherwise for shape and softnesse, it resembleth that of the Pomegranat: the flower is whiter; the smell & taste whereof is pestiferous and menaceth present death: it beareth cods like to Sesama, within which be graines or seeds foure square and thicke, but deadly unto all creatures that eat them. The leafe also is as venimous as the graine, yet otherwhiles there ensueth thereof a fluxe and gurrie of the belly, which saveth their life, or else there were no way but one.

Alexander Cornelius called that tree * Eone, whereof the famous ship Argo was made; and like it was (by his saying) to the Oke that carrieth Misselto, the timber whereof neither water will C putrifie, nor fire consume, no more than the Misselto it selfe. But so farre as ever I could learne, no man knew that tree but himselfe. * Or, *alonia.*

As for the tree Adrachne, all the Greekes in manner take Porcellaine for it; whereas indeed Porcellaine is an hearb, called in Greeke *Andrachne*; so as they differ in one letter: but Adrachne is a tree of the wild forrests growing upon mountaines, and never in the plaines beneath; resembling the Arbut or Strawberrie tree, save that the leaves be lesse, and never fade nor fall. And for the barke, rough and rugged indeed it is not, but a man would say it were frozen and all an yce round about, so unpleasant it is to the eye.

Like in leafe to Adrachne, is the tree Congygria, but otherwise it is lesse and lower. This propertie it hath, To loose the fruit wholly, togither with the soft downe that it beareth, which they call Pappus; a qualitie that no other tree hath, beside it. Like to Adrachne also is Apharce, and beareth fruit twice in one yeere, as well as it. The former is ripe, when the grape beginneth to bud and bloom; the latter, in the beginning of winter: but what manner of fruit this should be, I have not found written.

As touching the Ferula, it will not be amisse to speake thereof among forrein plants, yea and to raunge it among trees: for (as hereafter we will distinguish in the division of trees) some plants are of this nature, To shew all the wood they have, where the barke should be; that is to say, without-forth: and where the heart of the wood ought to be, they have nought but a light and spongeous pith, as the Elder; or els nothing at all, as Canes and Reeds. But to come to our Ferula before-named, it groweth in hot countries beyond-sea, with a stalke or stem full of knottie joints. Two kinds be knowne of them: for that which the Greeks call Narthex, groweth tall; but Narthecia is alwaies low. The leaves that put forth at the joynts, be ever biggest toward the ground: this plant otherwise is of the nature of Dill, and the fruit is not unlike. There is not a plant in the world lighter than it for the bignesse: being easie therefore to weld and carrie, the stem thereof serveth old men in stead of staves, to rest upon. The seed of this Ferula or Fenell-gyant, some have called Thapsia, but herein they be deceived, for that Thapsia doubtlesse is a kind of Ferula by it selfe, leafed like Fenell, with an hollow stalke, and never exceedeth in height the length of a walking-staffe: the seed is like to that of the Ferula, and the root white: cut it, there issueth forth milke; stampe it, you shall see it yeeld plentie of juice. Neither is the barke of the root rejected and cast aside, although both it, the milke, and the juice, be very poisons: for surely the root is hurtfull to them that digge it up; and if never so little of the aire thereof breath upon them (so venomous it is) their bodies will bolne and swell, their faces will be all overrun with a wild-fire: to prevent which mischiefes, they are forced to annoint their bodies with a receit. Howbeit as dangerous as they be, Physicians make use therof in the cure of many inward diseases, so they be well corrected and tempered with other safe medicines. In like manner they say, that the juice of

Thapſia is ſingular good for the ſhedding and falling of the haire; alſo againſt the blacke and blew marks remaining after ſtripes: as if Nature furniſhed not Phyſicians ſufficiently with other holeſome remedies, but that needs they muſt have recourſe to ſuch poiſonfull and miſchievous medicines. But this is the caſt of them all, to pretend ſuch colourable excuſes, for their handling of poiſons: and ſo impudent and ſhameleſſe are ſome beſides, that they baſh not to avow the uſe of them; bearing us in hand, that Phyſicke cannot ſtand without poiſon. The Thapſia in Affricke is the ſtrongeſt of all others. Some uſe to ſlit or cut the ſtem about harveſt, and in the very root make an hollow trough to receive the juice that runneth downe, and when it is dried, they take it away. Others againe doe bruiſe and ſtampe in a mortar, both leafe, ſtalke, and root; and when the juice that is preſſed there-from, is throughly dried in the Sunne, they reduce the ſame into certaine Trochiſques. *Nero Cæſar* the Emperour in the beginning of his Empire, gave great credit unto Thapſia: for uſing (as he did) to be a night-walker, and to make many ryots and much miſrule in the darke, he met otherwhiles with thoſe that would ſo beat him, as that hee carried away the markes blacke and blew in his face: but (as he was ſubtill & deſirous to avoid the ſpeech of the people) an ointment he had made of Thapſia, Frankincenſe, and Waxe, wherewith hee would annoint his face, and by the next morning come abroad with a cleare skin, and no ſuch markes to be ſeene; to the great aſtoniſhment of all men that ſaw him. To conclude, the Ferula maketh the beſt matches to keepe fire, by all mens confeſſion: and thoſe in Ægypt excell the reſt, for that purpoſe.

Chap. xxiii.

Of Capparis, or Cynosbatos, or Opheoſtaphyle: and of Sari.

Likewiſe in Ægypt groweth Capparis, a ſhrub of a harder and more woodie ſubſtance: well knowne for the ſeed and fruit that it carrieth, commonly eaten with meats, and for the moſt part the Capres and the ſtalke are plucked and gathered togither. The outlandiſh Capres (not growing in Ægypt) wee muſt take good heed of and beware: for thoſe of Arabia be peſtilentiall and venomous: they of Affricke be hurtfull to the gumbs, and principally the Marmarike are enemies to the mattice, and breed ventoſities. The Apulian Capres cauſe vomit, and make lubricitie both of ſtomack and bellie. Some call the ſhrub Cynosbatos: others, Opheoſtaphyle. Moreover, there is a plant of ſhrubs kind, called Sari: it groweth along Nilus, almoſt two cubits high, it beareth an inch in thickneſſe, and hath leaves like to Papyr reed, and men do chew and eat it after the ſame manner. As touching the root, it is ſingular good for Smithes cole to burne in their forges, ſo hard it is and durable.

Chap. xxiiii.

Of the Royall thorne of Babylon: and of Cytiſus.

I May not over-paſſe that plant, which about Babylon is ſowed upon Thornes onely: for otherwiſe it knoweth not how to live no more than Miſſelto, but upon trees: howbeit this plant that I ſpeake of, is ſowed upon that Thorne alone called the Royall Thorne. And a ſtraunge thing it is of this plant, That it ſpringeth and groweth the very ſame day that it is ſet or ſowed. Now the ſeaſonable time of ſowing it, is at the very riſing of the Dog-ſtarre: and notwithſtanding the Sunnes heat, right quickly overſpreadeth it the tree or ſhrub, on which it is caſt. The Babylonians uſe to aromatize their wine therewith; and for that purpoſe are they ſo carefull to ſow it. But the foreſaid Thorn tree groweth alſo about the long walls of Athens [reaching from the tower to the haven Pyræum.]

Moreover, a ſhrub there is, called Cytiſus, highly commended and wondrous much praiſed by *Ariſtomachus* the Athenian, for feeding of ſheep; as alſo for fatting of ſwine, when it is drie: and he promiſeth and aſſureth, That an acre of land ſowed therewith, although it be none of the beſt ſoile, but of a meane and ordinarie rent, will yeeld yeerely [*communibus annis*] 2000 Seſtercesto the maſter. As great profit commeth thereby, as of the pulſe like Vetches, called Ervum: but ſooner will a beaſt be ſatisfied therewith, and a very little thereof will ſerve to fat the ſame: inſomuch as if horſes or any ſuch labouring cattell may meet with that provender, they will not care for barley: neither is there any other graſſe or fodders, that yeeldeth more or better milke,

milke than it: but that which paſſeth all, the paſturage of Cytiſus, preſerveth Sheepe, Goats, and ſuch like cattell, ſound and ſafe from all diſeaſes whatſoever. Over and beſides, if a nource want milke, *Ariſtomachus* preſcribeth her to take Cytiſus drie, and ſeeth it in water, and ſo to drinke it with wine: whereby not onely her milke will come againe in great plentie, but the babe that ſucketh thereof, will bee the ſtronger and taller. Hee giveth it alſo to hens and pullein whiles it is greene, or ſteeped and wet, if it chance to bee drie. *Democritus* and *Ariſtomachus* both doe promiſe and aſſure us, that Bees will never miſcarie nor faile, if they may meet with Cytiſus to feed upon. And yet there is not a thing of leſſe charge to maintaine than it. Sowne it is commonly in the Spring with Barley, I meane the ſeed thereof, as they uſe to ſow leekes or porret ſeed: or elſe they ſet plants and ſlips thereof from the ſtalke, in Autumne before midwinter. If the ſeed be ſowne, it ought to be ſteeped and moiſtened before: yea, and if there fall no ſtore of raine after it is in the ground, it had need to be watered. As for the plants when they be a cubite long, are replanted in a trench a foot deepe. Otherwhiles the tender quicksets are planted about the Æquinoxes, to wit, in mid-March and mid-September. In three years they come to their full growth. They uſe to cut it downe in the Spring-Æquinox: when it hath done flouring: a worke that a very lad or old woman may doe, even ſuch as can skill of nothing els beſides. This Cytiſus is in outward hew white: and in one word, if a man would pourtray the likeneſſe thereof, it reſembleth for all the world a ſhrub of Trifolie or Clavergraſſe, with narrower leaves. Being thus gathered, it is ever given to beaſts once in three daies. And in winter, that which is dried ought to be wet before they have it. Ten pound of it is a ſufficient foddering for an horſe: and for other ſmall cattell according to the proportion. But by the way, this is not to be omitted, that it is good to ſet Garlicke and ſow Onions ſeed betweene the rewes and rankes of Cytiſus where it groweth, and they will thrive more plenteouſly. This ſhrub was firſt diſcovered and knowne in the Iſland Cythnus, and from thence tranſlated into all the other Iſlands Cyclades: and ſoone after brought to all the cities of Greece; whereupon followed great increaſe of milke, and plentie of cheeſe. I marvell therefore very much, that it is ſo geaſon and rare in Italie: and a plant it is that feareth neither heat nor cold; no injurie of haile, nor offence by ſnow; and as *Hyginus* ſaith, it is not afraid ſo much as of the enemie; the reaſon is, becauſe the wood thereof is nothing beautifull to the eie.

Chap. xxv.

Of ſhrubs and trees growing in our Mediterranean ſea, in the red ſea, and the Indian ſea.

EVen the very ſea affourdeth ſhrubs and trees: but thoſe of the Mediterranean ſea bee farre leſſe than of other ſeas: for the red ſea and all the Levant Ocean is full of woods. That which the Greekes call φῦκος, hath no other name in any language. As for Alga, is a word appropriate rather to weeds or ſea-hearbes, called Reik: but this Phycos is a very ſhrub, bearing broad leaves of a greene colour, which ſome call Praſon, others Zoſter. A ſecond kind there is of Phycos, with an hairie leafe like to Fennell, and groweth upon rockes. As for the former called Zoſter, it is found among the ſhelves and ſhallow waters not farre from the ſhore: both the one and the other appeare in the Spring, and be gone in the Autumne. That of this kind which groweth in Candie about the rockes, is much uſed of diers for the purple colour: and namely, on the North part of that Iſland, and among ſponges, for that is moſt commendable for this purpoſe. A third ſort there is like unto the graſſe called *Goich* or *Dent-de-chien*, having a root full of joints and a ſtalke likewiſe, in manner of a reed.

Another ſhrub there is in that ſea called Bryon, with leaves of Lettice, ſave onely that they be more wrinckled and crumpled together: but this groweth more inward and farther into the ſea. Marie in the deepe, groweth both Firre and Oke to the height of a cubite. Among theſe braunches, the Cockles and Muskles, and ſuch like ſhell-fiſhes doe ſettle and ſticke unto them. As for that kind of ſea Oke, ſome ſay it is of good uſe to die wooll withall: as alſo that it beareth maſt or acornes in the deepe: the knowledge of all which we come unto by thoſe that dive into the bottome of the ſea, and ſuch as have ſuffered ſhipwracke and eſcaped. Moreover (by report) there be other exceeding great trees, and namely about Sycione. As for the ſea vine, it groweth every where: but the fig-tree there is without leaves, & hath a red barke. There be alſo Date trees found

in the ſea: but as little as ſhrubs. Without *Hercules* pillars, or the ſtreight of Gebraltar, there are ſhrubs to bee ſeene, bearing leaves reſembling Leeke-blades: and others leaved like to the Bay tree, or to the hearbe Thyme: and both kinds being caſt up a land, turne into the pumiſh ſtone. But in the Eaſt parts it is a wonderous matter to thinke, that ſo ſoone as ever a man is paſt Coptus, he ſhall find nothing to grow in all the wilderneſſe, but onely a kind of thorne or thiſtle, called the thirſtie or drie thorne, and the ſame but here and there, in very few places: whereas in the red ſea, whole woods doe live, and namely, of Baies and Olives bearing their berries: alſo when it raineth, certaine Muſhromes, which no ſooner bee caught with the Sunnes heat, but they turne into the pumiſh ſtone. As touching the ſhrubs there growing, they be commonly three cubites high, and thoſe ſo full of ſea dogs and curres, that a man ſhall hardly looke out of the ſhip in ſafetie, for that many times they will take hold of the very oares, and aſſaile them. The ſoldiors of *Alexander* the Great who ſailed into India, made report, That the branches and leaves of the ſea trees, ſo long as they were under the water looked greene, but when they be taken forth, preſently dried with the heat of the Sunne, and became ſalt. Alſo that about the ſhore they found ſtonie ruſhes and reeds, like unto naturall ruſhes indeed. Moreover, in the deepe ſea they light upon certaine little trees braunched and full of boughes, in colour of an Oxe horne, but the head or top of them was red: handle them in your hand, they were as brittle as glaſſe: put them into the fire, they would bee red hote like yron: quench them againe, they returned to their former colour. In the ſame tract, there bee ſome tides ſo high, that the ſea overfloweth and covereth the woods growing within the Iſlands, although there be trees in them taller than the higheſt Planes or Poplars. And thoſe trees bear leaves like Lawrell, and flowers for ſmell and colour reſembling the Violet. Their berries bee like to Olives, and thoſe of a pleaſant and ſweet ſavor, which they bring forth in the Autumne: and their leaves never ſhed but continue all the yeare long. The lower ſort of theſe trees the floud covereth all and whole: but the greateſt beare up their heads above the ſea, whereunto the mariners doe faſten and tie their veſſels, at a high water: but when it is ebbe, at the very root. Moreover, by their ſaying they ſaw other trees in the ſame ſea, with leaves ever greene upon them, carrying a fruit like to Lupines. King *Iuba* reporteth, That about the Iſlands of the Troglodites there groweth a ſhrub within the ſea, called Iſidos Plocamos, [*i. Iſis* haire] reſembling corrall, and void of leaves: cut a braunch of it from the ſtock, it becommeth hard, changeth colour and is blacke: if it fall, it is ſo tender, that it will breake like glaſſe. Hee ſpeaketh moreover of another called Charito-blepharon, which is of great force in amatorious matters to procure love: And thereof women (quoth hee) make them carkanets and pendant ornaments to hang about their neckes. To conclude, he affirmeth, that this ſhrub hath a certaine intelligence when a man would take hold of it, and therefore waxeth as hard as an horne, inſomuch as it is able to turne the edge of a knife or bill, that unneath or hardly it may be cut: but in caſe it be entrapped and drawne up with cords without any edge toole, it preſently turneth to be a ſtone.

THE

THE XIIII. BOOKE OF THE HISTORIE OF NATVRE, WRITTEN BY C. PLINIVS SECVNDVS.

Containing the Treatiſe of Trees bearing fruit.

The Proëme.

THus farre forth have wee diſcourſed of all forraine and ſtraunge trees in a manner, ſuch I meane as know not how to live in any other places but where they naturally firſt did grow, and which willingly goe not into other countries, nor can abide their ſoile or aire. Good leave may I now have to write of Plants and Trees common to all lands, and namely, to ours of Italie, which may ſeeme to bee the very Hort-yard and naturall garden that bare them all. This onely would I advertiſe the readers and learners to remember, that for this preſent we purpoſe to deſcribe their natures and vertues onely, leaving out the manner of husbandrie that belongeth unto them: albeit in their tending and keeping appeareth the greateſt part of their properties, and of Natures workes. And verily, I cannot chuſe but marvell ſtill and never give over, how it comes to paſſe, that the remembrance, yea, and the very names of ſome trees which auncient writers have delivered in their bookes, ſhould bee quite gone and aboliſhed. For who would not thinke, that our life ſhould ere this have gained much by the majeſtie of the Roman Empire; have diſcovered all things by the meanes of the commerce we have had with the univerſall world, by the trafficke, negotiation, and ſocietie I ſay that we have entred into during the bleſſed time of peace which we have enjoied? conſidering that by ſuch trade & entercourſe, all things heretofore unknown, might have come to light. And yet for all this, few or none (beleeve me) there are who have attained to the knowledge of many matters which the old writers in times paſt have taught and put in writing. Whereby we may eaſily ſee, that our auncеſtors were either farre more carefull and induſtrious, or in their induſtrie more happie and fortunate. Conſidering withall, that above two hundred years paſt Heſiodus *(who lived in the very infancie of learning and good letters) began his worke of Agriculture, and ſet downe rules and precepts for husbandmen to follow. After whoſe good example, many others having travelled and taken like paines, yet have put us now to greater labour. For by this meanes wee are not onely to ſearch into the laſt inventions of later writers, but alſo to thoſe of auncient time, which are forgotten and covered with oblivion, through the ſupine negligence and generall idleneſſe of all mankind. And what reaſons may a man alledge of this drowſineſſe, but that which hath lulled the world aſleepe? The cauſe in good faith of all, is this and none other, Wee are readie to forgoe all good cuſtomes of old, and to embrace novelties and change of faſhions: mens minds now adaies are amuſed and occupied about new fangles, and their thoughts bee rolling; they wander and rove at randon; their heads be ever running; and no arts & profeſsions are now ſet by and in requeſt, but ſuch as bring pence into our purſes. Heretofore whiles kings and potentates contained themſelves within the dominion of their owne nations, and were not ſo ambitious as now they bee, no marvell if their wits and ſpirits kept ſtill at home: and ſo for want of wealth and riches of fortune, were forced to employ and exerciſe the gifts of their mind: in ſuch ſort as an infinite number of princes were honored and renowned for their ſingular knowledge and learning. Yea, they were more brave in port, and carried a goodlier ſhew in the world for their skill in liberall ſciences, than others with all their pompe or riches: being fully perſuaded and aſſured, that the way to attaine unto immortalitie and everlaſting fame, was by literature and not*

by

by great poſſeſsions and large ſeignories. And therefore as learning was much honoured and rewarded in thoſe dates, ſo arts & ſciences tending to the common good of this life daily encreaſed. But afterwards when the way was once made to enlarge their territories farther in the world, when princes and ſtates began to make conqueſts and grow rich and mightie, the poſteritie felt the ſmart and loſſe thereby. Then began men to chuſe a Senatour for his wealth; to make a judge for his riches; in the election of a civile magiſtrate and martiall captaine, to have an eie and regard onely to goods and ſubſtance, to land and living: when rents and revenues were the cheefe and onely ornaments that made men ſeeme wiſe, juſt, politike, and valiant. Since time that childleſſe eſtate was a point looked into, and advaunced men into high place of authoritie and power: procuring them many favourites in hope of ſucceſsion; ſince time I ſay that every man aimed and reached at the readieſt meanes of greateſt lucre and gaine, ſetting their whole mind, and repoſing their full content and joy in laying land to land, and heaping together poſſeſsions; downe went the moſt precious things of this life, and loſt their reputation: all theſe liberall arts which tooke their name of libertie and freedome, (the ſoveraigne good in this world which were meet for princes, nobles, gentlemen, and perſons of great ſtate) forwent that prerogative, and fell a contrarie way, yea, and ran quite to wracke and ruine: ſo as in ſtead thereof, baſe ſlaverie, and ſervitude be the only waies to ariſe and thrive by: whiles ſome practiſe it one way, ſome another, by flattering, admiring, courting, crouching, and adoring: and all, to gather good and get money. This is the only marke they ſhoot at, this is the end and accompliſhment of all their vowes, praiers, and deſires. Inſomuch as we may perceive every where, how men of high ſpirit and great conceit are given rather to honour the vices and imperfections of others, than to make the beſt of their owne vertues and commendable parts. And therfore we may full truly ſay, that Life indeed is dead; Voluptuouſneſſe and Pleaſure alone is alive, yea, and beginneth to beare all the ſway. Nevertheleſſe, for all theſe enormities and hinderances, give over will not I to ſearch into thoſe things that bee periſhed and utterly forgotten, how ſmall and baſe ſoever ſome of them be; no more than I was affrighted in that regard, from the treatiſe and diſcourſe of living creatures. Notwithſtanding that I ſee Virgil *(a moſt excellent Poet) for that cauſe onely forbare to write of gardens and hort-yards, becauſe he would not enter into ſuch pettie matters: and of thoſe ſo important things that he handled, he gathered only the principall flowers, & put them down in writing. Who albeit that he have made mention of no more than 15 ſorts of grapes, three kinds of Olives, and as many of Peares, and ſetting aſide the Citrons and Limons, hath not ſaid a word of any apples; yet in this one thing happie & fortunat he was. For that his worke is highly eſteemed, and no imputation of negligence charged upon him. But where now ſhall we begin this treatiſe of ours? what deſerveth the cheefe & principall place, but the Vine? In which reſpect Italie hath the name for the very ſoveraigntie of Vineyards: inſomuch, that therein alone, if there were nothing els, it may well ſeeme to ſurpaſſe all other lands, even thoſe that bring forth odoriferous ſpices and aromaticall drugs. And yet to ſay a truth, there is no ſmell ſo pleaſant whatſoever, that outgoeth Vines when they bee in their freſh and flouring time.*

Chap. 1.

Of Vines, their nature, and manner of bearing.

VInes in old time were by good reaſon for their bigneſſe reckoned among trees. For in Populonia, a citie of Tuſcane, wee ſee a ſtatue of *Jupiter* made of the wood of one entire Vine, and yet continued it hath a world of yeares uncorrupt and without worme. Likewiſe at Maſſiles there is a great ſtanding cup or boll to be ſeene of Vine wood. At Metapontum there ſtood a temple of *Juno*, bearing upon pillars of Vine wood. And even at this day there is a ladder or paire of ſtaires up to the temple of *Diana* in Epheſus, framed of one Vinetree, brought (by report) out of the Iſland Cypres, for there indeed Vines grow to an exceeding bigneſſe. And to ſpeake a truth, there is no wood more durable and laſting than is the Vine. Howbeit, for my part I would thinke that theſe ſingular peeces of worke beforenamed, were made of wild and ſavage Vines: for that theſe our tame and gentle Vines here planted among us, are by cutting and pruning every yeare kept downe: ſo as all their whole ſtrength is either drawne without-forth into branches, or els downward into the root for to put out new ſhoots ever freſh out of the ground: and regard is onely had of the fruit and juice that they doe yeeld diverſe waies, according to the temperature of the aire & climate, or the nature of the ſoile wherein they be planted. In the countrey of Campaine about Capua, they bee ſet at the roots of Poplers, and (as it were) wedded

unto

unto them: and so being suffered to wind and clasp about them as their husbands, yea, and with their wanton armes or tendrils to climbe aloft, and with their joints to run up their boughes, they reach up to their head, yea, and overtop them: insomuch as the grape-gatherer in time of Vintage, putteth in a clause in the covenants of his bargaine when hee is hired, that in case his foot should faile him, and he breake his necke, his maister who sets him aworke should give order for his funerall fire and tombe at his owne proper cost and charges. And in truth Vines will grow infinitely: and unpossible it is to part them, or rather to plucke them from the trees which they be joined and coupled unto. *Valerianus Cornelius* making mention of many properties and singularities of a Vine, thought this among the rest worthie of especiall note and remembrance, That one onely stocke of a Vine was sufficient to compasse, and environ round about a good fermehouse or countrey messuage, with the branches and pliable shoots that it did put forth. At Rome there is one Vine growing within the cloistures of the porches and galleries built by the Empresse *Livia*, which running and trailing upon an open frame of railes, covereth and shaddoweth the ouvert allies made for to walke in: and the same Vine yeeldeth one yeare with another a dosen Amphores of good new wine yearely. An ordinarie thing it is, that Vines will surmount any Elmes whersoever, be they never so tall and loftie. It is reported, that *Cyneas* the Embassadour of king *Pyrrhus*, wondering at the Vines of Aricia, for that they grew and mounted so high; would needs tast of the wine that came of their grapes: and finding it to bee hard and tart, merrily skoffed and said, That by good right and justice they had done well, to hang the mother that bare such unpleasant wine, upon so high a gibbet. Beyond the river Po in Italie, there is a tree growing which the peasants there call Rumbotinus, and by another name *Opulus; it putteth forth great armes and boughes, and those spread broad and beare a round compasse, howbeit, the Vines that be planted at the root of these trees, doe fill and cover the said boughes: for yee shall have the very old crooked braunches of the Vine (bare as they be and naked of leaves) to wind about the armes, and crawle in manner of a serpent or dragon along the broader and flattey base of the boughs, and then the new shoots, toptwigs, and tendrils, will devide themselves to the utmost branches and shoots of the tree, that they will lode and clog her withall. These Vines again grow sometime no taller than the ordinarie height of a man of middle stature, and being supported and underpropped with stakes and forkes, cleave and cling thicke together, and in this order fill whole Vineyards. Others also there bee, which with their excessive creeping upon frames, with their overgrowne braunches, and some artificiall helpe of the maisters hand, spread so far every way, that they take up wide and large courts, overspreading not onely the sides, but the very mids thereof. See what sundrie sorts of Vines even Italie alone is able to affourd! But in some provinces without Italie, ye shall see a Vine stand of it selfe without any prop or stay at all, gathering and drawing in her boughes and braunches together: thus indeed she groweth but short, howbeit so close couched and trussed round, that the thickneese makes amends for all. And yet otherwhiles in some coasts the winds are so big and boisterous, that they will not suffer them thus to grow upright; as namely in Affricke, and Languedoc, the province of Narbon. Vines being thus debarred to run up in height, resting upon their owne joints and braunches, and ever like to those that be laid along whiles they are a trimming, by delving about their roots, and pruning their superfluous branches, traile and creepe too and fro along the ground, as weedes and hearbes; and all the way as they spread, sucke the humor of the earth into their grapes: by which meanes, no marvell it is, if in the inland parts of Affricke there bee found some of those grapes bigger than pretie babes. And in no countrie are the grapes of a thicker skin than those of Affricke, whereupon it may well be, that they tooke the name *Duracina* [*i.* having hard skins.] For infinite sorts there be of grapes, according to the difference observed in their quantitie and bigneese, in their colour, tast, stones or kernils: and yet more still, in regard of the divers wines made of them. In one place they are of a fresh and bright purple, in another, of a glittering, incarnate, and rosate colour: and yee shall have them of a faire and lively greene. As for the white and blacke grapes, they be common every where. The grapes Bumasti have their name, for that they bee so swelling and round, like strutting paps or dugs. The Date-grapes Dactyli, are long, both grape and kernill, fashioned in manner of fingers. Moreover, Nature seemeth to take her pleasure and make good sport in some kind of them; where ye shall find among them some that be exceeding great, others againe that be as small, howbeit pleasant they are, and as sweet as the rest: and such be called Leptorhagæs. Some last all winter long, being knit in bunches together, and so hanged aloft

*Opiet.

*Quasi durie acinis.

arch-

arch-wise in maner of a vault: with others they make no more ado, but put them up presently as they come from the Vine, into earthen pots, whiles they be fresh & in their vigor; and afterwards they are bestowed, well lapped over with their leaves, in other greater vessels over them; and for to keepe them better, they be stopped close with kernels heaped and piled upon, sweating round about, to condite and preserve them in their naturall heat. Others they suffer to be dried in the smoke of smiths forges, wherby they get the very tast of enfumed wine, so ordered in the smoke. And in truth *Tiberius Cæsar* the Emperour gave especiall credite and name by his example to such grapes dried in the furnaces of Affricke. For before his time, the Rhetian grapes and those that came out of the territorie of Verona, were ordinarily served up to the table first, for the very best. As for the Raisins called Passæ, they tooke that name in Latine of their patience to endure their drying and confiture. Some grapes there be that are condite in Must or new wine, and so they drinke their owne liquor wherein they lie soking, without any other seething. Others againe are boiled in Must abovesaid, untill they loose their owne verdure, and become sweet and pleasant. Moreover, yee shall see old grapes hang still upon the Vine their mother, untill new come: but within glasses, that a man may see them easily through: howbeit, to make them to last and continue in their full strength, as well as those which bee preserved in barrels, tuns, and such like vessels aforesaid, they use the helpe of pitch or tarre, which they poure upon the stalkes that the cluster hangeth to, and wherewith they stop close the mouth of the said glasse. It is not long since that there was a devise found, that wine of it selfe (as it came naturally from the grape growing upon the Vine) should have a smacke and sent of pitch. And surely this kind of *Pitch-wine, brought the territorie about Vienna into great name and reputation: and before that this Vine was knowne, those of Auverne, Burgundie, and the Helvij, were in no request at all. But these devises as touching Vines and Wines, were not in the daies of the Poët *Virgil*, who died about nintie yeares past. But behold what I have to say more of the Vine-tree: the Vine wand is now entred into the campe, and by it our armies are raunged into battaillons: nay, upon the direction thereof dependeth the maine estate of our soveraigne Empire: For the Centurion hath the honour to carie in his hand a Vine-rod: the good guidance and ordering whereof advaunceth after long time the Centeniers (for a good reward of their valorous and faithfull service) from the leading of inferiour bands, to the captaineship of that regiment and cheefe place in the armie, unto which the maine standard of the Ægle is committed: yea, and more than that, the Vine wand chastiseth the trespasses and lighter offences of the souldiors; who take it for no dishonour nor disgrace to be thus punished at their Centurions hand. Over and besides, the planting of Vineyards hath taught martiall men how to approch the walls of their enemies, to give an assault under a frame devised for the purpose, which thereupon took the name of Vinea. Lastly, for medicinable vertues in Physicke, the Vine is so profitable to mans health, that the use of it alone is a sufficient remedie for the distemperature of mans bodie, caused by wine it selfe.

* πιτίτης οἶνος. Plutarch.

Chap. 11.

Of the diverse kinds of Vines.

Democritus was the onely Philosopher ever known, who made profession to reduce all the sorts and kinds of Vines to a certaine number, and indeed he vaunted and made his boast that he had the knowledge of all things that were in Greece. All others besides himselfe, and those comming nearer to the truth, (as shall appear more evidently by the varietie of wines) resolutely have set downe, that there be infinite sorts of Vine-trees. Looke not therefore at my hands, that I should write of them all, but onely of the principall: for that in truth there bee in manner as many and as sundrie kinds of them, as are of grounds. Wherefore I will content my selfe, and thinke it sufficient to shew those that bee singular and most renowned among them, or such as have some secret proprietie worth admiration. And first to begin with the Aminean Vines, all the world giveth them the cheefe praise and greatest name; as well for their grapes, of so lasting and durable a nature, as for the wine made thereof, which in all places continueth long in vigor, and is ever the better for the age. And hereof there be five sundrie sorts. Of which, the kindly Vines named Germanæ, have both lesse grapes and graines within, but they burgen and bloume better than others: and after the flower is gone, they can abide both raine and tempest. But the second kind (which is the greater) is not so hardie: howbeit, lesse subject to wind & weather

ther when they be planted to run up a tree, rather than to creepe upon a frame. A third ſort are called Gemellæ,for that their grapes grow double like twins,and they be very harſh and in taſt untoothſome,howbeit their vertue and ſtrength is ſingular. The ſmaller ſort of theſe take harm by the South wind: but all other winds nouriſh them,as we may ſee in the mount Veſuvius, and the little hils of Surrentum: for in all other parts of Italie, yee ſhall never find them but wedded to trees,and growing upon them. As for the fift kind of theſe Amminean Vines,they bee called Lanatæ,ſo freezed they are with a kind of downe or cotton,inſomuch as we need not wonder any more at the Seres or Indians for their cotton and ſilken trees. The firſt kind of theſe Amminean grapes come ſooneſt to their ripeneſſe and perfection,and moſt quickly do they rot and putrifie. Next to theſe Amminean Vines, thoſe of Nomentum are in moſt account: and for that their wood is red,ſome have called them Rubellæ. Theſe grapes yeeld no great plentie of wine, but inſtead thereof their ſtones and kernils, and other refuſe remaining, grow to an exceeding big cake: howbeit,this propertie they have. The froſt they will endure paſſing well, leſſe harme they take alſo by raine than drought,and thrive better in cold than heat: and therefore in cold and moiſt grounds they excell and have no fellow. Of theſe Vines, they are more plentifull which beare grapes with ſmaller ſtones, and leaves with leſſe cuts and jags endented. As touching the Muſcadell Vines, Apianæ,they tooke that name of Bees,which are ſo much delighted in them, and deſirous to ſettle and feed of them. Of two ſorts they are: and both carie cotton and down. Howbeit,this difference is betweene them,that the grapes of the one will bee ſooner ripe than the other, and yet there is neither of them both but be haſtie ynough. Theſe Muſcadell grapes like well and love cold countries: and yet none ſooner rot than they,if ſhowers take them. The Muſcadell wines are at the firſt ſweet: but with age become harſh and hard, yea, and red withall. And to conclude,there is not a grape that joieth more to hang upon the vine,than it doth. Thus much of the very flower of Vines,and the principall grapes that be familiar and proper unto our countrey of Italie,as their native ſoile.

The reſt be ſtraungers come out of Chios or Thaſos. As for the Greeke grapes of Corinth, they be not in goodneſſe inferior to the Aminean aforeſaid. They have a very tender ſtone within: and the grape it ſelfe is ſo ſmall, that unleſſe the ſoile be exceeding fat and battle,there is no profite in planting and tending ſuch Vines. The quicke-ſets of the Vine Eugenia were ſent unto us from the Tauromenitane hils in Sicilie,together with their ſurname pretending a noble and gentle race. Howbeit,they are never in their kind with us, but onely in the Albane countrey: for if you tranſplant them,they prove very baſtards and changelings preſently. And in faith,ſome Vines there be that take ſuch an affection and love to a place, that all their goodneſſe and excellencie they will leave there behind them, and never paſſe into another quarter whole and entire as they be in their owne nature. Which evidently is to bee ſeene in the Rhetian Vine,and that of Savoy and Dauphinie,of which in the chapter before we ſaid,that it gave the taſt of pitch to the wine made thereof: for,theſe Vines at home in thoſe countries are much renowned for the ſaid taſt: but elſewhere if they be tranſplanted,they looſe it whole, and no ſuch thing may a man acknowledge in them. Howbeit,plentifull ſuch are,and for default of goodnes,they make amends and recompence in abundance of wine that they yeeld. As for the Vine Eugenia,it taketh well in hote grounds. The Rhetian liketh better in a temperate ſoile. The Allobrogian Vine of Savoy and Daulphine delighteth moſt in cold quarters: the froſt it is that ripeneth her grapes,& commonly they are of colour blacke. Of all the grapes above rehearſed,the wines that be made, the longer they be kept,the more they change colour,& in the end become white, yea,though they came of blacke grapes,and were of a deepe colour at firſt. Now for all other grapes whatſoever, they are reckoned but baſe in compariſon of the former. And yet this is to bee noted and obſerved,that the temperature of the aire may be ſuch, and the ſoile ſo good,that both the grapes will endure long,and the wine bear the age very well. As for example,the Vine Fecenia,and likewiſe Biturica, that bloumeth with it, which beare grapes with few ſtones within: their flowers never miſcarie,for they ever prevent and come ſo timely,that they be able to withſtand both wind and weather. Howbeit,they doe better in cold places than in hote: in moiſt alſo,than in drie. And to ſay a truth,there is not a vine more fruitfull, and yeelding ſuch ſtore of grapes growing ſo thicke together in cluſters: but of all things it may not away with variable and inconſtant weather: let the ſeaſon be ſtaied and ſettled,it matters not then whether it bee hot or cold,for well it will abide the one and the other alone,hold it never ſo long. The leſſer of this kind is held for the better.

Howbeit

Howbeit, in chooſing of a fit ſoile for this vine, it is much adoe to pleaſe and content it: in a fat ground it ſoone rotteth; in a light and lean, it will not grow at all: very choiſe it is therefore, daintie, and nice, in ſeeking a middle temper betweene, and therefore it taketh a great liking to the Sabine hills, and there it loves to be. The grapes that it beareth, be not ſo beautifull to the eye, but pleaſant to the tooth: if you make not the more haſt to take them preſently when they be ripe, they will fall off, although they bee not rotten. This vine putteth foorth large and hard leaves, which defend the grapes well againſt haileſtones.

Now there are beſides, certain notable grapes of a middle colour between black and purple, and they alter their hue oftentimes; whereupon ſome have named them Varianæ: and yet the blacker they be, the more they are ſet by: they beare grapes but each other yeare, that is to ſay, this yeare in great plentie, the next yeare very little: howbeit, their wine is the better when they yeeld fewer grapes. Alſo there be two kinds of vines called Pretiæ, differing one from the other in the bigneſſe of the ſtones within the grape: full of wood and braunches they are both: their grapes are very good to be preſerved in earthen pots: and leafed they be like to Smallach. They of Dyrrhachium doe highly praiſe the Roiall vine Baſilica, which the Spaniards call Cocolobis. The grapes grow but thin upon this plant: they can well abide all South winds, and hote weather: they trouble and hurt the head, if a man eat much of them. In Spaine they make two kinds of them; the one having a long ſtone or grain within, the other a round: theſe be the laſt grapes that are gathered in time of vintage. The ſweeter grape that the Cocolobis beareth, the better is it thought: howbeit that which was hard and tart at the firſt, will turne to bee pleaſant with keeping; and that which was ſweet, will become harſh with age: and then they reſemble in taſt, the Albane wine: and men ſay, there is an excellent drinke made thereof, to helpe diſeaſes and infirmities of the bladder. As touching the vine Albuëlis, it beareth moſt grapes in the tops of trees, but Viſula is more fruitfull beneath toward the root: and therefore if they be ſet both under one and the ſame tree, a man ſhall ſee the diverſitie of their nature, and how they will furniſh and enrich that tree, from the head to the foot. There is a kind of blacke grape, named Inerticula, as a man would ſay, dull and harmeleſſe; but they that ſo called it, might more juſtly have named it The ſober grape: The wine made therof is very commendable when it is old, howbeit nothing hurtfull * for never maketh it any man drunke: and this propertie hath it alone by it ſelfe. As for other vines, their fruitfulnes doth commend them; and namely above all, that which is called Helvenaca: wherof be two kinds; the greater, which ſome name The long: and the ſmaller, called Area: not ſo plentifull it is as the former, but ſurely the wine thereof goeth downe the throat more merrily. It differeth from the other in the perfect and exquiſite wonders of the leafe, as it were drawne by compaſſe: but both the one and the other is very ſlender, and therefore of neceſſitie they muſt be underpropped with forkes, for otherwiſe they will not beare their own burden, ſo fruitfull they be. They delight greatly to grow neare the ſea ſide, where they may have the vapours of the ſea to breath upon them: and indeed their very grapes have a ſent and ſmell of a brackiſh dew. There is not a vine can worſe brooke Italie. Her grapes are ſmall, they hang thin, and rot even upon her: and the wine made thereof, will not laſt above one Summer: and yet on the other ſide there is not a vine that liketh better in an hungrie and leane ground. *Græcinus* (who otherwiſe compiled his worke out of *Cornelius Celſus* in manner word for word) is of this opinion, That this vine could love Italie well enough, and that of the owne nature it miſliketh not the countrey; but the cauſe why it thriveth no better there, is the want of skill and knowledge to order and husband it as it ought to bee; for that men ſtrive to overcharge it with wood, and load it with too many braunches: and were it not that the goodnes of a fat and rich ſoile maintained it ſtill, beginning to faint and decay, the fruitfulneſſe thereof were enough to kill it. This vine (by report) is never blaſted: a ſingular gift verily of Nature, if it be true, That any plant or tree ſhould bee ſo exempt from the juriſdiction (as it were) of the heavens, that they had no power to doe it harme. The vine Spionia, which ſome call Spinea, feareth no extremitie of heat: her grapes proſper well in Autumne and much abundance of raine: This is the only grape that is nouriſhed with foggie miſts, and therefore it liketh no place well but the territory of Ravenna. The vine Venicula (which is counted one of the beſt for kindly blooming and ſhedding the flowers, and for grapes moſt meet to be preſerved and kept in pots) the Campaines rather name Sirculus; others Stacula: and they of Tarracina call it Numiſiana: and as they ſay, the grape therof hath no ſingularitie nor vertue in it ſelfe, but only according to the ſoile where

* Amethyſtos, *Columell.*

it

it groweth: howbeit thoſe that grow about Surrentum, have the moſt ſtrength, and are excellent to bee preſerved in veſſels; I meane, as farre as up to the hill Veſuvius: for there alſo is the vine Murgentina, the beſt of all thoſe that come out of Sicilie, which ſome call Pompeiana, of Pompeij, a towne within the kingdome of Naples: & being gotten once into Latium, it beareth grapes abundantly: like as the vine Horconia in Campaine, yeeldeth plentie of grapes with the beſt, but good they are for nothing ſave only to be eaten at the table. As for the grape Mærica, it will laſt and endure a long time; it feareth neither wind nor tempeſt, nor any blaſt of planet: blacke it is, and hath blacke ſtones: howbeit the wine that it maketh, waxeth red with age, namely, if it be long kept.

Chap. iii.

Of the divers kinds likewiſe of vines according to the propertie of the places and regions where they grow.

HItherto have we treated of the ſundrie ſorts of vines in generall: now will we write of them according to the nature of the places and regions, which are proper and familiar unto them; or, as they be mingled one with another, by tranſplanting or grafting. And firſt and formoſt, the vine Tudernis; alſo Florentia (bearing the name of the citie Florence) are peculiar to the Tuſcans: but about Aretium, there is no talke both for plentie and goodneſſe, but of the Talpana, Eteſiaca, and Conſeminia. The Talpane grape is blacke as the Mouldwarpe, whereof it taketh the name, but yet doth it yeeld a white wine. The Eteſiacke vine [ſo called of the wines Eteſiæ] is a deceitfull plant, and often miſſeth and faulteth; but the more grapes it beareth, the better wine it yeeldeth and more commendable: mary this is ſtraunge and wonderfull in it, In the mids of this fruitfulneſſe of hers, ſhe giveth over ſodainly and dieth. The vine Conſeminia, bringeth blacke grapes: the wine will not laſt, but the grapes will keepe and continue paſſing long: the vintage thereof is fifteene daies after all other: it beareth ordinarily her full burden, but the fruit is onely good for meat to be eaten, and not for wine to be drunke. The leaves of this vine (in manner of the wild vine Labruſca) before they fall, become as red as bloud. This propertie happeneth to ſome others beſides; but take it for a certaine token of the worſt vines. The vine and grape Irtiola, is proper unto Vmbria, to the territorie of the Mevenates, and the Picene countrey: like as that which they call Pumula, to the Amiternine region. They have among them alſo another kind, named Bannanica: and although it oftentimes doth not take, yet they love the plant and cheriſh it. There is a grape which they call the Burrough or Burgeois grape, after the name of the burrough towne Pompeij; and yet there is more plentie of them about the citie Cluſium. The Tiburtines alſo, named their grapes after their town Tybur: yet of late daies they have found another ſort, which of the reſemblance of Olives, is called the Olive grape: and in truth, this is the laſt grape of any account, to this day knowne to have been found out. The Sabins and Laurentines only are acquainted with the grape Vinaciola: for well I wot, that the vines Gauranæ came firſt out of the territorie of Falerij, and thereupon were named Falernæ: but tranſplant them from thence whitherſoever you will, they will very quickly degenerat in all places, & prove baſtard. Moreover, ſome have made a ſeveral kind by it ſelfe of the Tarentin vine, which bringeth forth an exceeding ſweet grape. As for the grapes called Capnias, Bucconiatis, and Tarrupia, there is no vintage of them in the vineyards of the hils about Thurinum, before the cold froſt. As for the citizens of Piſæ, they ſet great ſtore by the grapes Phariæ: like as Modenna by thoſe called Pruſiniæ; which are very black, ſtone and all: yet the wine therof, within foure yeeres will turne to a pallet and whitiſh colour. A ſtraunge thing it is which men report of a certaine grape, that evermore will turne with the Sunne; and thereupon it is called Streptos: as alſo that we in Italie are delighted with the French grapes: and they in Fraunce beyond the Alpes, are as much in love with ours in the Picene countrey. *Virgill* hath made mention of other grapes, namely, Thaſiæ, Marcotides, and Lageæ, beſides many other outlandiſh plants, not at this day to be found throughout all Italy. Howbeit there be yet many vines of good marke & well accepted of, not for any wine that they yeeld, but only for their grapes which they carie; to wit, Ambroſiaca, and Duracina, which may be kept hanging ſtill upon the vine, without any veſſell to encloſe them: ſo durable be they and hardie, againſt cold, heat, wind, and rain, or any weather whatſoever. As for the vine Orthampelos, it needs neither tree to climb on, nor

forkes to ſupport it, but is able to maintaine and uphold it ſelfe upright. But the Dactylides (ſo called for that they beare not wood above a finger thicke) cannot ſo doe: for they muſt be ſhored and underpropped. Of all vines, the Columbines yeeld moſt gleaning, for that the gatherers leave behind them greateſt ſtore of ſmall grapes: and ſo doe the purple grapes, named alſo Bimammiæ (as one would ſay, with two teats or bigs) more than the reſt; ſeeing that they beare not ſmall grapes, but put forth new great ones indeed, after the other be gathered and gone. In like manner, the vine Tripedanea, which tooke that name of the meaſure of three foot. Semblably the vine Scirpula, the grapes wherof ſeeme as if they were Raiſons of the Sunne, dried alreadie. Moreover, in the maritime Alpes toward the ſea ſide, there is a kind of Rhetian vine, but far inferiour to that other above-mentioned and ſo much commended for the relliſh of pitch that it giveth to the wine made of her grapes: for theſe about the Alpes be little and ſmall; and albeit they beare grapes thicke, yet the wine thereof commeth farre ſhort of the other, and is more degenerate: howbeit the skin of the grapes is of all other the thinneſt, having but one kernell within, which they call Gigarton, and the ſame very ſmall; and a man ſhall not find a bunch, without one or two paſſing great grapes above the reſt. There is alſo a kind of blacke Aminean grape, which ſome name Syriaca: likewiſe the grape of Spaine, which of the baſe and common kinds carrieth the greateſt credit, and is moſt commended. As touching both vines and grapes that run and traile upon frames; there be thoſe which are called Eſcariæ, good only for to eat, and namely thoſe which have graines or ſtones like to Ivie berries, as well white as black. Grapes reſembling great dugs, named thereupon Bumaſti, both blacke and white, are caried upon frames in like ſort. But all this while we have not ſpoken of the Ægyptian and Rhodian grapes, ne yet of the Ounce-grapes, whereof every one weigheth a good ounce, and thereupon tooke that name. *Item*, the grape Pucina, the blackeſt of all others: the Stephanitis alſo, wherein Nature hath ſeemed to diſport her ſelfe, for the leaves runne among the grapes in manner of a guirland plaited with them. Moreover, the market-grapes called Forenſes, they grow and are ripe with the ſooneſt; vendible at the very firſt ſight, and ſold with the beſt, and moſt eaſie to be carried from market to market. But contrariwiſe, the aſh-coloured grape Cinerea, the ſilke-ruſſet grape Ravuſcula, the aſſe-hued grape Aſiniſca, pleaſe not the eye, but are preſently rejected: and yet the fox-tailed grape Alopecis (for that it reſembleth Rainards-taile) is not ſo diſpleaſant nor ſo much diſcommended as the former. About a cape or creſt of the hill Ida, which they call Phalacra, there is a vine named Alexandrina, ſmall of growth, and putteth forth braunches of a cubit in length: the grapes be blacke, as big as beanes; the pepin or kernell within, ſoft, tender, and exceeding ſmall; the bunches are crooked, full of grapes, paſſing ſweet; & finally, the leaves little, round, and not cut or jagged at all. Within theſe ſeven yeeres laſt paſt, about Alba Elvia, a citie in Languedocke or the province of Narbon, there was found a vine, which in one day both flowred and ſhed her flowers: by which meanes moſt ſecured it was from all daungers of the weather. They call it Narbonica, or the vine of Languedoc: and now it is commonly planted all that province over, and every man deſireth to ſtore his vineyard therewith.

Chap. iiii.

Notable conſiderations about the husbandrie and ordering of Vineyards.

THat noble and worthy *Cato*, the firſt of that name, renowmed among other dignities for his honorable triumph, and the incorrupt adminiſtration of his Cenſorſhip; & yet more famous and renowmed to poſteritie for his ſingular knowledge and learning; and namely for the good precepts and ordinances tending to all vertues and commendable parts, which hee left in memorie for the people of Rome; and principally as touching agriculture [as he was by the common voice and generall accord of that age wherein hee lived reputed for an excellent husbandman, and one who in that profeſſion had neither peere nor ſecond that came near unto him.] This *Cato* (I ſay) hath in his workes made mention but of a few kinds of vines: and yet ſome of them alreadie be growne out of knowledge, ſo as their very names are quite forgotten. Yet nevertheleſſe his opinion and judgement would be ſet downe in particular, as it may be gathered out of his whole treatiſe: to the end that we might both know in every kind of vine which were of moſt account in his daies (to wit, in the 600 year after the foundation of Rome, about the

the time that Carthage and Corinth were forced and woon, when hee departed this life:) and alſo learne how much we have profited and proceeded in good husbandrie and agriculture, from his death unto this preſent day; namely for the ſpace of 230 yeares. As concerning vines and grapes therefore, thus much hath *Cato* delivered in writing, and in this manner following. *All places or grounds* (quoth he) *expoſed to the Sun-ſhine, and which in other regards ſhall be found good for to plant vineyards in, ſee they be employed for the leſſe Aminean, for both the Eugenian vines, and the ſmaller Helvine. Item, In every tract that is more groſſe, thicke, and miſty, looke that you ſet the greater Aminean, or the Murgentine: the Apician alſo, and the Lucane vine. All other vines, and the common mingled ſort eſpecially, will agree well enough with any ground. The right keeping of grapes, is in a ſmall thin wine of the ſecond running. The grapes Duracinæ, and the greater Amineans, are good to be hanged, or elſe dried before a black-ſmithes forge, and ſo they may be well preſerved, and goe for Raiſons of the Sunne.* Loe what the precepts of *Cato* be; neither are there any of this argument more auncient, left unto us written in the Latine tongue. Whereby we may ſee, that wee live not long after the very firſt rudiments and beginnings of knowledge in theſe matters. [But by the way, the Amineans laſt named, *Varro* calleth Scantians.] And in very truth, few there be even in this our age, who have left any rules in forme of Art, as touching the abſolute skill in this behalfe. Yet ſuch as they be, and how few ſoever, wee muſt not leave them behind, but ſo much the rather take them with us; to the end it may be known, what reward and profit they met with, who travailed in this point of husbandrie: reward, I ſay, and profit, which in every thing is all in all.

To begin therefore with *Acilius* * *Sthenelus*, (a meane commoner of Rome deſcended from the race of Libertines or Slaves newly enfranchiſed) he attained to the higheſt glorie and greateſt name of all others: for having in the whole world not above ſixtie acres of land lying all in vineyards within the territorie of Nomentum, he plaied the good husband ſo well therein, that he ſold them againe at the price of 400000 Seſterces. There went a great bruit and fame likewiſe of one *Verulenus Aegialus*, in his time a man but of baſe condition by birth, and no better than the former (namely, come of the ſtocke of freed-men) who by his labour and husbandrie, greatly enriched a domaine or living at Liternum in Campaine: and the more renowmed hee was by occaſion of the favour of ſo many men affectionate unto *Africanus*, whoſe very place of exile he held in his hands and occupied ſo well: for unto *Scipio*, the aboveſaid Liternum appertained. But the greateſt voice and ſpeech of men was of *Rhemnius Palæmon* (who otherwiſe by profeſſion was a famous and renowmed Grammarian) for that hee by the meanes and helpe of the foreſaid *Sthenelus*, bought a ferme within theſe twentie yeares for 600000 Seſterces in the ſame territorie of Nomentum, about ten miles diſtant from Rome, lying ſomewhat out of the high way. Now it is well knowne farre and neare, of what price and account all ſuch fermes are, and how cheape ſuch ware is lying ſo neare to the city ſide: but among the reſt, this of *Palæmons* in that place was eſteemed moſt cheape and loweſt priſed, in this regard eſpecially, That he had purchaſed thoſe lands, which through the careleſneſſe & bad husbandrie of the former owners, lay neglected and fore-let, and were not of themſelves thought to be of the beſt ſoile, choſen and piked from among the worſt. But beeing entred once upon theſe grounds as his owne livelode and poſſeſſion, he ſet in hand to husband and manure them, not ſo much of any good mind and affection that he had to improove and better any thing that he held, but upon a vaineglorie of his owne at the firſt, whereunto he was wonderouſly given: for he makes fallows of his vine-plots anew, and delveth them all over againe, as he had ſeene *Sthenelus* to do with his before: but what with digging, ſtirring, and medling therewith, following the good example and husbandrie of *Sthenelus*, he brought his vineyards to ſo good a paſſe within one eight yeeres, that the fruit of one yeares vintage was held at 400000 Seſterces, and yeelded ſo much rent to the lord: a wonderfull and miraculous thing, that a ground ſhould bee ſo much improoved in ſo ſmall a time! And in verie truth, it was ſtraunge to ſee what numbers of people would run thither, only to ſee the huge and mightie heapes of grapes gathered in thoſe vineyards of his: and all idle neighbours about him, whoſe grounds yeelded no ſuch encreaſe, attributed all to his deepe learning, and that he went to it by his booke, & had ſome hidden ſpeculation above other men; objecting againſt him, that he practiſed Art Magicke, and the blacke Science. But laſt of all, *Annæus Seneca*, eſteemed in thoſe daies a ſingular clerke, and a mightie great man, (whoſe overmuch learning and exceeding power coſt him his overthrowing in the end) one who had good skill and

* or, *Stelenus*.

judgement in the world, and used least of all others to esteeme toies and vanities, brought this ferme into a greater name & credit: for so farre in love was he of this possession, that he bought out *Palæmon*, and was not ashamed to let him goe away with the prick and praise for good husbandrie, and to remoove him into other parts where he might shew the like cunning: and in one word, paid for these foresaid vineyards of his fourfold as much as they cost, not above ten years before this good husbandrie was bestowed upon them. Certes, great pitie it is, that the like industrie was not shewed and emploied in the territories about the hills Cecubus and Setinus, where (no doubt) it would have well quit all the cost, considering that many a time afterwards, every acre of vineyard there, yeelded seven Culei, that is to say, 140 Amphores of new wine one year with another. But least any man should thinke, that we in these daies have surpassed our auncestors in diligence, as touching good husbandrie; know he, that the abovenamed *Cato* hath left in writing, How of an acre of vineyard there hath arisen ordinarily * ten Culei of wine by the yeare. Certainly these be effectuall examples and pregnant proofes, that the hardie and adventurous voiages by sea, are not more advantageous; ne yet the commodities and merchandise, and namely Pearles, which be fet as farre as the red sea and the Indian ocean, are more gainfull to the merchant, than a good ferme and homestall in the countrey, well tilled and carefully husbanded.

* 15, according to *Ful. Vrsinus.*

As touching the Wines in old time, *Homer* writeth, that the Maronean wine made of the grapes growing upon the sea-coast of Affricke, was the best and most excellent in his daies. But my meaning is not to ground upon fabulous tales and variable reports, as touching the excellencie or antiquitie of wine. True it is, that *Aristæus* was the first, who in that very nation mingled honey with wine; which must needs be a passing sweet and pleasant liquor, made of two natures so singular as they bee of themselves. And yet to come againe to the foresaid Maronean wine, the same *Homer* saith, That to one part thereof, there would be put twentie parts of water: and even at this day, that kind of wine continueth in the said land of the same force, and the strength thereof will not be conquered nor allaied. For *Mutianus*, who had been thrice Consull of Rome, and one of those that latest wrote of this matter, found by experience (being himselfe personally in that tract) that every sextar or quart of that wine, would beare eight of water: who reporteth moreover, that the wine is of colour blacke, of a fragrant sweet smell, and by age commeth to be fat and unctious. Moreover, the Pramnian wine, (which the same *Homer* hath so highly commended) continueth yet in credit and holdeth the name still: it commeth from a vineyard in the countrey about Smyrna, neare to the temple of *Cybele* the mother of the gods. As for other wines, no one kind apart excelled other.

One yeare there was, when all wines proved passing good; to wit, when *L. Opimius* was Consull, at what time as *C. Gracchus* a Tribune of the Commons (practising to sow sedition within the citie among the common people) was slaine: for then such seasonable weather happened, and so favourable for all fruit, that they called it (Coctura) as a man would say, the ripening time; so beneficiall was the Sunne to the earth: and this fell out in the yeere after the nativitie & foundation of the citie of Rome, 634.

Moreover, there be some wines so durable, that they have been knowne to last two hundred yeeres; and are come now by this time to the qualitie and consistence of a rough, sharpe, and austere kind of honey: and this is the nature of all when they bee old: neither are they potable alone by themselves, unlesse the water be predominant; so tart they are of the lees and so mustie withall, that they are bitter againe. Howbeit a certaine mixture there is of them in a very small quantitie with other wines, that gives a pretie commendable taste unto them. Suppose now, that according to the price of wine in those daies of *Opimius*, every Amphore were set but at an hundred Sesterces, yet after the usurie of six in the hundred yeerely (which is the ordinarie proportion and a reasonable interest among citizens, for the principall that lyeth dead and dormant in stocke) by the hundred and sixtieth yeere after the said Amphore was bought (which fell out in the time that *C. Caligula Cæsar* the sonne of *Germanicus* was Emperour) no marveile if an ounce in measure of the same wine (to wit, the twelfth part of a Sextarius) cost * so many Sesterces: for as we have shewed by a notable example, when we did set downe the life of *Pomponius Secundus* the Poët, and the feast that he made to the said prince *Caligula*, there was not a * Cyathus of that wine drawne, but so much was paid for it. Loe what a deale of money lieth in these wine-cellars, for keeping of wine! And in very truth, there is nothing more gainfull nor groweth to a

* *Bud.* 22 Sest.

* 1. an ounce and a halfe.

better

A better reckoning than it, for twentie yeares ſpace after it is laid up: neither is there greater loſſe againe by any thing, if ye paſſe that tearme; by reaſon that the price will not grow and ariſe accordingly: for ſeldome hath it been knowne to this day, (and never but at ſome exceſſive ryot and ſuperfluous expence of wine) that an Amphore hath been ſold for a thouſand Seſterces. True it is indeed, that they of Vienna only have made a better reckoning of their wines, and ſold them deerer; I meane thoſe that give a taſt of pitch, (the ſeverall kinds whereof we have delivered before:) but they are thought ſo to doe among themſelves onely, and for the love of their countrey, that it might have the name of wines, ſo deere and coſtly. To conclude, this wine of Vienna, is reputed colder than the reſt; when the queſtion is of cold drinke, and that the bodie is to be cooled.

B

Chap. V.

Of the nature of Wine.

THe nature and propertie of wine, is to heat the bowels within, if it be drunke; and to coole the exteriour parts, if it be applied outwardly. And here it ſhall not be amiſſe to rehearſe in this very place, that which *Androcydes* (the noble, ſage, and wiſe Philoſopher) wrote unto King *Alexander* the Great, for to correct and reforme his intemperate drinking of wine, whereto he was very prone and over-much given: *My good lord* (ſaith he) *remember when you take your wine, that you drinke the very blood of the earth: Hemlocke* (*you know Sir*) *is poiſon to man, even ſo is wine to Hemlocke.* Now if that Prince had been ſo wiſe as to have obeyed theſe precepts of his, C certes, he could never have killed his beſt friends as he did, in his fits of drunkenneſſe. In ſumme, this may be truly ſaid of wine, That being taken ſoberly and in meaſure, nothing is more profitable to the ſtrength of the bodie; but contrariwiſe, there is not a thing more dangerous and pernicious, than the immoderate drinking thereof.

Chap. VI.

Of kindly Wines made of the beſt Grapes.

WHo doubteth, that ſome wines be made more pleaſant and acceptable than others? nay out of the very ſame vat ye ſhall have wines not alike in goodnes, but that ſome go before their brethren, preſſed though they be at one time, and from the ſame kind of D grape: which may be long either of the veſſell whereinto they be filled, or of ſome accidentall occaſion: and therefore as touching the excellencie of wine, let every man be his own taſter and judge. The Empreſſe *Iulia Auguſta* would commonly ſay, That ſhe was beholden to the Pucine wine for living as ſhe did 82 yeares: for ſhe never uſed to drinke any other. This wine came of the grape that grew along the Adriaticke ſea, or Venice gulfe, upon a ſtonie and raggie hill, not farre from the ſource or ſpring of the river Timavus, nouriſhed with the vapours breathed from the ſea; and many Amphores there were not drawne thereof at a vintage: and by the judgement of all men, there is not a wine more medicinable than it is. I would thinke verily therefore, that the wine Pyctanon (which the Greekes ſo highly praiſe) is the very ſame; for it commeth from E the coaſts of the Adriaticke ſea. The Emperor *Auguſtus Cæſar* preferred the Setine wine before all others: and after him in manner, all the Emperours his ſucceſſours, for the ordinarie experience they found thereby, That lightly the liquor of that wine would not hinder digeſtion nor breed raw humors in the ſtomacke: and this wine commeth of the grape about the towne Forum Appij. Before that time, the wine Cæcubum was in beſt account; and the vines which yeelded it, grew to the Poplars in the mariſh grounds within the tract of Aniyclæ. But now is that wine cleane gone, as well through the negligence of the paiſants of that countrey, as the ſtreights of the place: and ſo much the rather, by reaſon of the ditch or trench which *Nero* cauſed to be made navigable, beginning at the lake or gulfe Bajanus, and reaching as farre as to Oſtia. In the ſecond degree of excellencie, are ranged the wines of the Falerne territorie, and principally that F which came from the vineyards Fauſtian: and this excellencie it grew unto by paſſing good order & carefull husbandrie. Howbeit this wine alſo in theſe daies beginneth to grow out of name and requeſt, whiles men love rather to have plentie from their vines, than otherwiſe lay for the goodnes thereof. Now theſe Falerne vineyards, begin at the Campaine bridge on the left hand as men go to the city-colonie erected by *Sylla*, and lately laid to Capua & under the juriſdiction thereof.

thereof. But the Fauſtian vineyards lie about foure miles from a village neare Cediæ, which village is from Sinueſſa ſix miles diſtant. And to ſay a truth, this Fauſtian wine is inferiour to none in reputation: ſo piercing and quicke it is, that it will burne of a light flame; a propertie that you ſhall not ſee in any other wine. Three ſorts there be of theſe Falerne wines: the firſt be hard and harſh; the ſecond, ſweet and pleaſant; the third, thin and ſmall. But ſome have diſtinguiſhed them in this wiſe: Thoſe that come from the top of the hills, be called Gaurane wines; from the mids, Fauſtian; and laſt of all from the bottome and foot thereof, the Falerne. But by the way this would not be forgotten, That the grapes whereof be made theſe wines ſo ſingular and excellent, are nothing pleaſant to the taſt for to be eaten. As touching the Albane wines from about Alba neare the citie of Rome, they reach to the third ranke in goodnes, for a certaine varietie they have in their taſt: ſweetiſh they be, and yet otherwhiles they have an unripe and harſh relliſh of the wood, & taſt like the hedge-wine. In like manner the wines of Surrentum, & namely thoſe of grapes growing onely in vineyards, are excellent good for weake perſons that be newly recovered of ſickneſſe; ſo ſmall they are, and holeſome withall. And in truth, *Tyberius Cæſar* was woont to ſay, That the Phyſicians had laid their heads togither, and agreed to give the Surrentine wine ſo great a name; for otherwiſe it was no better than a very mild and pleaſant vinegre: and *C. Caligula* (his ſucceſſor in the Empire) uſed to ſay of it, That for a wine that had loſt the heart and was a going, it was verie good. The Maſſike wines, which come from the Gaurane hills looking toward Puteoli and Bajæ, come nothing behind the reſt, but ſtrive to match them every way. For as touching the Statane vineyards, that confine and border upon the Falerne, their wines doubtleſſe are now come to be the principall and chiefe of all the reſt: whereby it is evidently ſeene, that every territorie and vine-plot hath their times and ſeaſons, like as all other things in the world, one while riſe and another while fall. For in times paſt, the Calene wines made of the grapes growing hard by Rome, were wont to goe before all others: as alſo the Fundane vines had their time, as well thoſe that are planted in vineyards, as they which run upon trees: like as thoſe of the other ſide, neare alſo to the citie of Rome, and namely from Veliternum and Privernum. For as touching the wine of Signia, it is held for a medicine onely; and by reaſon of an aſtringent verdure that it hath, it is excellent good to ſtay the flux of the belly. In the fourth place of this race of vines, *Iulius Cæſar* (late Emperour of famous memorie) hath raunged (for to ſerve the publicke and ſolemne feaſts of the cittie) the Mamertine wines, from about Meſſana in Sicilie: for he was the firſt (as appeareth by his letters miſſive) that gave credit and authoritie unto them. And of thoſe, the Potulane wines (ſo called of them who firſt planted the vines wherof they came) are moſt commended, & namely thoſe that are upon the next coaſt of Italy. Within the ſame Sicilie, the Tauromenitane vines are highly eſteemed, inſomuch as many times they goe for Meſſana wine, and are ſo ſold by whole pottles. Now for all other wines from about the coaſt of the Tuſcane ſea Northward, good reckoning is made of the Prætutian and ſuch as come from Ancone: alſo of the Palmeſian wines, which haply tooke that name, for that the firſt plant of that vine came from a Palme or Date tree. But in the midland parts of Italie within the firme land, good regard there is of the Ceſenatian and Mecænatian wines. Within the territorie of Verona, the Rhetian wine carrieth the price: which *Virgill* ranged next after the Falerne wines. Anon you come to the wines Adriane, and thoſe that grow far within the tract of the Venice gulfe. Now from the nether ſea about Lions, ye have the Latinienſian, the Graviſcane, and the Statonian wines. Throughout all Tuſcane, the wines about Luna beare the name: like as thoſe of Genes, for Liguria. Betweene the Pyrenæan hills and the Alpes, Maſſiles hath the commendation for wines of a double taſt: for the vines there, do yeeld a certain thicke and groſſe wine, which they call Succoſum, [*i.* full of juice and liquor] good to ſeaſon other wines, and to give them a pretie taſt. When ye are paſſed once into Fraunce or Gaule, the wine of Beterræ is in chiefe requeſt. As for the reſt within Languedoc and the province of Narbon, I am not able to avouch any thing for certaintie, ſuch a brewing and ſophiſtication of them they make, what with fuming, perfuming, and colouring them: and would God they put not in ſome hearbs and drugs among, that be not good for mans bodie. For certaine it is, that they commonly buy Aloë to give the wine both another taſt and alſo a counterfeit color. Moreover, in the farther and more remote coaſts of Italie toward the Auſonian ſea, there be wines which are not without their praiſe and commendation, and namely thoſe of Tarentum, Servitium, and Conſentia: likewiſe of Tempſa, Bavia, and Lucania: howbeit the Thurine wine goeth before

fore them all. As for the wines of Lagaria, which bee made of the grapes not farre from Grumentum, there goeth a right great name of them, by reaſon that *Meſſala* uſed ordinarily to drink thereof, and thereby was ſuppoſed to preſerve his health ſo well. Of late daies there bee certain wines in Campaine growne into credite (like as they have gotten new names) by good ordering and husbandrie, or by chaunce, I know not whether; namely, thoſe of Trebellia, foure miles from Naples; of Caulium neare to Capua: and laſt of all, the Trebulaine wines within their own territorie: for beforetime they were ever counted no better than common wines for every man to drinke, no more than the Trifolines, from whence they vaunt of their deſcent. As for the wine of Pompeij, a towne in the kingdome of Naples, neither it nor the Vine whereof it commeth, will laſt above ten years at the moſt: after which tearme, the elder they both bee, the worſe they are. Beſides, they are found by experience to cauſe the headach, inſomuch, as if a man drink thereof over night, hee ſhall be ſure not to have his head in good tune untill noone the morrow after. By which examples above rehearſed, it is plaine in my conceit, that the goodneſſe of the wine ſtandeth much upon the ſoile and the climate, and not in the grape: ſo as a needleſſe and endleſſe matter it is to reduce all kind of wines to a certaine number, conſidering, that one and the ſelfeſame Vine planted in diverſe places, hath ſundrie operations, and maketh varietie of wines. Now as concerning the wines of Spaine, the Laletane vineyards are much ſpoken of for the plentie and abundance of wine that they yeeld: but thoſe of Tarracon, Arragon, and Laurone, are much praiſed and renowned for the fine and neat wines which they make. As for the wines that come out of the Iſlands, and namely, the Baleares, they are comparable to the very beſt in Italie.

I am not ignorant, that moſt men who ſhall read this Treatiſe, will thinke that I have omitted and overpaſſed many wines: for every man liketh his owne; and as ones fancie leadeth, ſo goeth the voice and the crie, and there runs the Hare away. It is reported, that one of *Auguſtus Cæſars* freed men (reputed for the fineſt taſter that hee had about his court, and who knew beſt what would content his pallat, and pleaſe his tooth) upon a time when he taſted the wine that was for the Emperours bourd, at what time as he made a feaſt, ſaid to one of the gueſts at the table, That the ſaid wine indeed had a new and ſtraunge taſt, and was none of the beſt, and thoſe that were in name; howbeit (quoth he) this is for the Emperours cup, and willingly will he drinke of no other, notwithſtanding it be but a homely wine made hereby in the countrey, and not far fetched. And now for a finall concluſion of this matter, I cannot denie but that there bee other wines which deſerve to bee numbred among thoſe that are right good and commendable, howbeit, ſuffice it ſhall to have written of theſe, which by the common opinion and conſent of the world are held for the better.

Chap. vii.

Of Wines beyond-ſea.

IT remaineth now to ſpeake of outlandiſh Wines beyond the ſea. Firſt and formoſt therefore, next to thoſe wines renowned by the Poët *Homer*, and whereof we have written before, beſt eſteemed alwaies were the wines of the Iſlands Thaſos and Chios: and namely that of Chios which they call Aruſium or Aruiſium. *Eraſiſtratus* the moſt famous Phyſician of his time, matched with theſe the Lesbian wine; and his authoritie gave credite unto it: & this was much about the ſixe hundred yeare after the foundation of Rome. But in theſe daies there is no wine to that of Clazomene, ever ſince that they began to put thereto leſſe ſea-water for to ſeaſon it, than their cuſtome was. As for the wine of Lesbos, it hath a ſent and relliſh of the ſalt water naturally of it ſelfe. Neither is the wine that commeth from the hill Tmolus in any regard, as a wine to be drunk alone, but it ſerveth as a ſweet cuit to mingle with other wines that bee hard: for thereby their greene verdure will ſeeme more mild and pleaſant, yea, and withall to have their ripe age: for no ſooner is it tempered therewith, but they taſt preſently elder than they bee. Next after theſe for goodneſſe, follow in their courſe the wines of Sycione, Cypres, Telmeſſus, Tripolis, Berytus, Tyrus, and Sebennys. As for this wine laſt rehearſed, it is made in Ægypt, a countrey much renowned for three kinds of grapes there, to wit, Thaſia, Æthalos, and Peuce. Next in price & account be theſe following, the Hippodomantian, the Myſticke, Cantharite, and the Gnidian wine of the firſt running and unpreſſed, alſo that of Catacecaumene, a region ſo called, for that it ſeemeth

meth all burnt; of Petra, and Mycone. As for the wine Mesogites, it is knowne to make head-ach: neither is the wine of Ephesus holsome & healthfull, because it is sophisticated with a kind of cuit halfe sodden, called Defrutum, and sea-water. As for the wine of Apamea, by report it commeth very neare to a kind of Mede, and will very well agree withall, like as Prætutium in Italie. For otherwise, this is the propertie in generall of all sweet wines, that they will not well sort together, & be good still. Touching the wine Protagium, it is now growne out of remembrance: and yet the Physicians of *Asclepiades* his sect and schoole, gave praise unto it next the Italian wines. The learned Physician *Apollodorus*, in his treatise that he compiled of good wines, which he recommended unto king *Ptolomæus* for to drink, as meet for the health of his person, (for default of Italian wines then unknowne) highly praised the wines in Pontus, and principally that which is called Naspercenites: next to it the Orœoticke, the Oeneates, that of Leucadia, of Ambracia; and (which he preferreth above all the rest) the wine of Peparethus: and yet hee said, that there went the lesse name and opinion of it, because after sixe yeares it looseth the strength and pleasant tast that it had.

Chap. viii.

Seven kinds of salt wine.

THus farre forth have we discoursed of the very flower of good wines, according to the regions where naturally they come of the grape. Now are wee to treat of wines compounded. And first, among such wines is that, which they called Biæon (an invention of the Greeks) which above all others was most esteemed: and great reason, for devised it was for the cure of many maladies, as we shall shew hereafter in our treatise of Physicke. The making whereof is in this manner: Take grapes gathered somewhat before they bee ripe: let them lie to drie and parch in the hot Sunne for three daies, and be turned duly thrice a day: upon the fourth day presse them forth for wine, put the liquor up in barrels, and so let it worke in the Sunne. Howbeit, hereto they put a good quantitie of salt sea-water. But this devise was learned first of a false theevish knave, who having robbed his maister and drunke up a good deale of his wine, filled up the vessell again and made just measure with sea-water. White wine if it bee ordered in this sort, is called Leucochrum by the Greekes: but in other nations the like wine so made is named Tethalassomenon. As for Thalassites, it is a kind of wine so called, for that the vessels when the wine is new tunned, be cast into the sea, and there let to remaine for a time, by which meanes the wine will soon seeme old and readie to be drunke. Furthermore, *Cato* also here among us hath shewed the way how to make the Greekish wine Coum, of our owne Italian wine: but above all hee hath set downe an expresse rule, to let it first take the maturitie and perfection foure yeares in the Sunne. As for the wine of Rhodes, it is much like to that of Coos. But the Phorinean wine is more salt than the wine of the Isle Coos. Finally, all transmarine or beyond-sea wines are thought in seven or sixe yeares at the least, to come unto their middle age.

Chap. ix.

Foureteene sorts of sweet wines.

ALwaies the sweeter that they be in tast, the lesse fragrant & odoriferous they are: the thinner and smaller that they be, the more ever they smell to the nose. Of wines there be foure principall colours, white, yellow, red, and blacke. As for Psythium and Melampsythium, they be certaine kinds of cuit, having a severall tast apart by themselves, not resembling wine indeed. And for Cicibelites made in Galatia, it tasteth alwaies like new wine: so doth Halyntium in Sicilie. For as touching Syræum, which some call Hepsema, and we in Latine Sapa [*i.* Cuit] it is a meere artificiall thing, the devise of mans wit, and no worke of Nature: namely, when new wine is sodden away a third part: for when it boileth to the halfe, we then call it Defrutum. And in very deed, all these bee inventions to sophisticate and counterfet honie. But those beforenamed retaine the naturall tast of the grape and the soile whereof they doe consist. Next to these cuit-wines of Candie; those of Cilicia, Affrick, Italie, and the provinces confronting thereupon, are held for the best. Certaine it is, That they be made of one grape, which the Greekes call Stica, and we Apiana [*i.* the Muscadell] and of another named Scirpula: the which have been suffered

fered a long time to hang in the Sunne upon the Vine untill they bee ſcorched and parched: or elſe over the vapour of ſcalding oile. Some there be that make them of any ſweet grapes whatſoever, ſo that they be let to concoct before in the Sunne, untill they be white and drie, ſo farre forth, as little leſſe than halfe of their weight be conſumed: which done, they ſtamp them and ſo gently preſſe them. Then looke how much liquor they have preſſed foorth, ſo much pit water they put to the cake that is preſſed, that thereof they may have a cuit of a ſecond running. But they that be more curious & take upon them to make a daintier cuit, drie the grapes in manner aforeſaid, but they take forth the ſtones and graines within: they ſtrip them alſo from the ſteeles and tailes that they hung by: and ſo after they bee well drenched and infuſed in ſome excellent wine, untill they bee ſwelled and plumpe, they preſſe them. And certainely this faſhion is ſimplie the beſt of all others. Put to the cake thereof, water as before, and after the ſame manner yee ſhall have a cuit of a ſecond ſort. Now there is a kind of wine which the Greekes call Aigleuces, that is to ſay, alwaies ſweet like new wine, of a middle nature betweene the common ſimple wine and the ſweet: and this commeth not unto it by kind, but by heed taken in the boiling; for it is not ſuffered to ſeeth and worke: and this is the tearme, wherby is ſignified the alteration of new Muſt into wine. To hinder therefore that it worke not, (as naturally it will) they have no ſooner tunned or filled it out of the Vat, but immediately they douſſe the veſſels full of new Muſt in the water, and let them there continue untill mid-December be paſt, and that the weather be ſetled to froſt and cold, and likewiſe the time expired of the working within the ſaid veſſels. Moreover, there is another kind of wine naturally ſweet, which in Provance & Languedoc is called Dulce [i. ſweet] and namely, in the territorie of the Vocontians. For this purpoſe they let the grapes hang a long while upon the Vine, but firſt they wryth the ſteele that the bunch hangeth to. Some make inciſion into the very Vine braunch, as farre as to the pith and marrow within (to divert the moiſture that feedeth the grape:) others lay the cluſters a drying upon tile-houſes: and all this is done with the grapes of the Vine Helvenaca. There be that range in a ranke of theſe ſweet wines, that which they call Diachyton. For which effect, they drie the grapes againſt the Sunne (howbeit in a place well encloſed) for ſeven daies together, upon hardles, ſeven foot likewiſe from the ground: in the night ſeaſon they ſave them from all dews, and ſo upon the eight day they tread them in the wine preſſe: and thus they draw forth a wine of an excellent ſavor and taſt both. A kind of theſe ſweet wines, is that which they name Melitites, [in manner of a Braget, Meade, or Metheglin.] Howbeit, different it is from meade or honied wine which the Latines call Mulſum; made of old wine that is hard, and a little honnie: whereas the foreſaid Melitites conſiſteth of five gallons of new tart wine ſtill in the verdure, whereto is added one gallon of honie, and a *cyath of ſalt, and ſo boiled all together. But I muſt not forget to place among theſe ſundrie kinds of drink, the liquor Protropum, for ſo ſome call new wine running it ſelfe from the grapes, before they bee troden and preſſed. But to have this good, and ſo to ſerve the turne, ſo ſoone as it is put up into proper veſſels for the purpoſe, it muſt be ſuffered to worke: and afterwards to reboile and worke againe for fortie daies ſpace the Summer followings even from the very beginning of the dog daies, and ſo forward.

* an ounce and a halfe.

Chap. X.

Of weake and ſecond Wines, three kinds.

THe ſecond Wines (which the Greekes call Dexateriæ, *Cato* and wee Romanes name Lora) cannot properly and truly be called Wines, being made of the skins and ſeeds of grapes ſteeped in water: howbeit, reckoned they are among courſe houſhold wines for the hines and meinie to drinke. And three kinds there be of them. For ſometime to the tenth part of the new wine that hath beene preſſed out, they put the like quantitie of water, and ſuffer the foreſaid refuſe of the grapes to ſoke therein a day and a night: which done, they preſſe it forth againe. A ſecond ſort there is, which the Greekes were wont to make in this manner: They take a third part of water in proportion of the wine that was preſſed forth, and after a ſecond preſſing, they ſeeth it to the waſting of the third part. The third is that which is preſſed out of the wine lees, and this *Cato* calleth Fœcatum, [i. Wine of lees.] But none of theſe wines or drinkes will endure above one yeare.

Chap.

Chap. xi.

What neat wines began of late to be in request in Italie.

IN this treatise of wines I cannot omit this observation: That whereas all the good wines, properly so called and knowne in the whole world, may bee reduced in foureſcore kinds or thereabouts; two parts of three in this number, may well be counted wines of Italie: which in this regard farre surpasseth all other nations. And hereupon ariseth another thing more deepely to be noted, That these good wines were not so rife nor in such credite from the beginning, as now they be.

Chap. xii.

Observations touching wine.

TO say a truth, Wines began to grow into reputation at Rome, about sixe hundred yeares after the foundation thereof, and not before. For king *Romulus* used milke when hee sacrificed to the gods, and not wine: as may appeare by the ceremoniall constitutions by him ordained, as touching religion; which even at this day bee in force, and are observed. And king *Numa* his successour made this law Posthumia in his latter daies, LET NO MAN BESPRINCKLE THE FUNERALL FIRE WITH WINE. Which Edict no man doubteth but he published and enacted in regard of the great want and scarcisitie of wine in those daies. Also by the same Act hee expressely did prohibite to offer in sacrifice to the gods, any wine comming of a Vine plant that had not ben cut and pruned: intending by this devise and pretence of religion, to enforce men to prune their Vines, who otherwise would set their minds upon husbandrie only and plowing ground for corne, and bee slow ynough in hazarding themselves for to climbe trees, whereunto Vines were planted. *M. Varro* writeth, That *Mezentius* the king of Tuscane aided the Rutilians of Ardea in their wars against the Latines, for no other hire and wage but the wine and the vines which then were in the territorie of Latium.

Chap. xiii.

Of the auncient usage of wine: and the wines in old time.

IN auncient time, women at Rome were not permitted to drinke any wine. We read moreover in the Chronicles, That *Egnatius Mecennius* killed his owne wife with a cudgell, for that he tooke her drinking wine out of a tun; and yet was hee cleared by *Romulus*, and acquit of the murder. *Fabius Pictor* in his Annales reporteth, That a certaine Romane dame, a woman of good worship, was by her owne kinsfolke famished and pined to death, for opening a cupbord, wherein the keies of the wine-sellar lay. And *Cato* doth record, that hereupon arose the manner and custome, That kinsfolke should kisse women when they met them, to know by their breath whether they smelled of Temetum: for so they used in those daies to tearme Wine: and thereof drunkennesse was called in Latin Temulentia. *Cn. Domitius* (a judge in Rome) in the like case pronounced sentence judicially against a woman defendant, in this forme, THAT IT SEEMED SHE HAD DRUNKE MORE WINE WITHOUT HER HUSBANDS KNOWLEDGE, THAN WAS NEEDFULL FOR THE PRESERVATION OF HER HEALTH, and therefore awarded definitively, That she should loose the benefit of her dowrie. Certes, the Romans for a long time made great spare of wine. *L. Papyrius* lord Generall of the Romane armie, when he was at the point to joine battell with the Samnites, made no other vow, but this, That he would offer unto *Iupiter* a little cup or goblet of wine, in case hee atchieved the victorie and woon the field. Over and besides, we find in histories, that among donatives and presents, certaine sextars or quarts of milke have been many times given, but never any of wine. The same *Cato* abovenamed, after his voiage into Spaine (from whence he returned with victorie and triumph) in a solemne speech that hee made unto the people, protested in these words and said, *No other wine have I drunke since I went, than the very marriners have.* How farre unlike was he to men in these daies, who sitting at the table, have their cup of strong wine by themselves, and give to their guests other small wines to drinke: or if they suffer them to drinke all one and of the best at the beginning of the feast, they will

will be ſure to chaunge and to ſerve them with worſe ſoone after. In old time, the beſt wines uſed at feaſts were aromatized and ſpiced with ſweet Myrrhe: as appeareth in the Comœdie of *Plautus* entituled Perſa. And yet it ſhould ſeeme there, that ſweet Calamus was to be added beſides. And hereupon it commeth, that ſome have thought, how our forefathers in times paſt tooke moſt delight in ſuch ſpiced cups and Ippocras wines. But *Fabius Dorſenus* the Poet, ſufficiently declareth and decideth this point in theſe verſes, when he ſaith:

Mittebam vinum pulchrum, Murrhinam.

I ſent neat wine,
Which hight Myrrhine.

And againe in his Comedie *Acharistio*:

Panem & Polentam, vinum Murrhinam.

Both bread and grewell I did preſent,
And Myrrhine wine of pleaſant ſent.

I ſee moreover, that *Scævola*, *Lælius*, and *Atteius Capito* were of the ſame mind. For in the Comedie of *Plautus* entituled *Pſeudolus*, thus it is written:

Quod ſi opus eſt ut dulce promat
Indidem, ecquid habet? Char. *Rogas?*
Murrhinam, paſſum, Defrutum, mella.

Of dulcet wine if there be need,
What hope is there from thence to ſpeed?
Char. Why aske you that? he furniſh'd is
With Murrhin, Cuits, and Meade ywis.

By which a man may ſee evidently, that Murrhina was not only counted a wine, but reckoned alſo among the ſweet and delicate wines.

Chap. xiiii.

Of wine ſtore-houſes: and of Opimian wine.

That there were wine-ſellars at Rome, and that they uſed there to tun up wine in the 633 yeare after the foundation thereof, appeareth plaine by a good proofe of the Opimian wine: and even in thoſe daies Italie knew her owne good, and what it was to maintain vineyards. Howbeit, as yet were not thoſe wines in credite, which now are ſo rife and in ſo great account. And therefore it is, that all the wines of that time beare the onely name of that one Conſull, and be called Opimian. And thus afterwards alſo in proceſſe of time, the wines that came from beyond the ſeas for a long ſpace, were in much requeſt, even untill our grand-fathers daies: yea, and after that, the Falerne wines were in name and called for, as may appeare by that verſe of the Comicall Poët:

Quinque Thaſij vini inde depromam, Falerni bina.

To meaſures five of Thaſian wine,
I will draw twaine of Falerne fine.

In the 675 yeare after the building of Rome, *Pub. Licinius Craſſus* and *L. Iulius Cæſar*, Cenſors for the time being, publiſhed an edict and proclaimed, That no man should sell any Greeke vvine or Aminean, but after eight Asses the Amphor or Quadrantum. For theſe be the very expreſſe words of the ſaid Edict. Now was Greeke wine of ſo great price and eſtimation, that a man was but allowed one draught thereof at a meale, were the cheare never ſo great, and the feaſt right ſumptuous. But what wines were in requeſt ordinarily at the bord, *M. Varro* ſheweth in theſe words: *L. Lucullus* (quoth he) while he was a boy, never ſaw at his

his fathers boord Greek wine ſerved up but once at a meale, how good ſoever the fare was otherwiſe. Howbeit, himſelfe when he returned out of Aſia, in a congiarie or largeſſe that hee gave unto the people, made a dole and diſtribution of more than an hundred thouſand meaſures, of gallons apeece. *C. Sentius*, whom of late daies we ſaw Pretour of Rome, teſtified, that hee never ſaw any wine of Chios brought into his houſe, before that the Phyſician preſcribed and ſet it downe for the *Cardiaca paſsio*, or the trembling of the heart, whereunto hee was ſubject. But contrariwiſe *Hortenſius* when he died, left above ten thouſand barrels full of that wine to his heire. And thus much out of *M. Varro*.

Chap. XV.

Of Cæſars bountie and liberalitie in wine.

BVt what ſhould wee ſay of *C. Iulius Cæſar* Dictatour? In that ſolemne feaſt of his which hee made at his triumph, did not he diſtribute among his gueſts Falern wines by the whole barrels, and Greeke wine of Chios by the rundlets? After his returne out of Spaine with victorie and triumph, he likewiſe gave away a largeſſe of wine as well Chian as Falerne. But at the roiall dinner which he made when he entred upon his third Conſulſhip, he cauſed all the hall to bee ſerved throughout with Falerne, Chian, Lesbian, and Mamertine wines: which was the firſt time that ever any man ſaw the ſervice of foure ſeverall wines at one feaſt. Now in farther proceſſe of time, and namely about the 700 yeare after Rome cities foundation, all other wines began to beare a name and come in requeſt.

Chap. XVI.

Of artificiall or made wines.

COnſidering all that hath beene written, I nothing marvell at ſuch an infinite numbers of compound and artificiall wines deviſed in old time, all for the uſe of Phyſicke, whereof wee will now treat in more ample manner. To begin therfore with Wine-verjuice called Omphacium, how it ſhould be made (for perfumes and odoriferous ointments) wee have ſhewed in the former booke. As for the wine named Oenanthinum, it is made of Labruſca, that is to ſay, the wild Vine, in this wiſe: Take two pound of the flowers of the wild Vine aforeſaid; let the ſame bee ſteeped in a meaſure of new wine, containing about twelve *gallons, for the ſpace of thirtie daies, and then be chaunged out of that veſſell into another. Moreover, the root and the grapes of the ſaid wild Vine, are good for curriers to dreſſe their leather. The ſame grapes a little after they have done blooming, are taken to be a ſingular remedie for to coole thoſe that be troubled with hote and ardent diſeaſes, for naturally they be (as men thinke) exceeding cold: and indeed many of theſe grapes die in the hote time of Summer before the reſt which are called Solſtitiales: but all of them never come to full and perfect ripeneſſe. Now if you would keepe Pullein from pecking grapes, take theſe of the wild Vine before they be throughly ripe, mingle & ſeeth them with their meat: for this will take away all their appetite that way, and breed a loathing after all grapes.

*12 congios.

To come now unto the artificiall wines beforenamed: the firſt of them, namely that which they call Adynamon, [*i.* without ſtrength] is made of very wine in this manner: Take of new white wine twentie Sextars [*i.* quarts:] of water halfe as much: let them boile together untill the meaſure of water beforeſaid bee conſumed. Some take of ſea-water ten Sextares, of raine water as much: and when they be mingled together, ſuffer them to worke in the hote Sunne for the ſpace of fortie daies. This drinke they uſe to give unto patients, for ſuch maladies as they feare wine would be hurtfull to. A ſecond made wine there, is called Millet wine, after this ſort: Take of Millet ſeed that is ripe, huske, head and all, a pound and a quarter, put it into two gallons of Muſt or new wine: after that it hath lien there infuſed ſeven moneths, let the liquor run from it into another veſſell, and keepe it for your uſe. As touching the wines of Lotus, as well the tree and ſhrub, as the hearbe, wee have ſhewed ſufficiently how they ought to be made. Moreover, there bee many wines made of ſundrie fruits, which wee will write of hereafter more at large: with a ſupplement and addition of ſuch interpretations onely as be neceſſarie. And in the firſt place commeth the Date-wine, which the Parthians, Indians, and all the nations of the Eaſt in generall

A nerall doe ordinarily uſe. A Modius or pecke of ripe and ſweet Dates, which they call Chydeæ, they let lye to ſteepe in three gallons of water, and ſo preſſe for a liquor for the Date wine. Alſo the Figge-wine Sycites, of the figge which ſome call Palmiprimum (as a man would ſay, Dates fellowes, or next to Dates) others Catorchites, is made after the ſame faſhion. But if a man liſt not to have it ſo ſweet, in ſtead of water they uſe to put as much of the ſtones, skins, and ſeeds of grapes. Of the Figge of Cypreſſe there is an excellent vinegre made: yea and a better than it of the Alexandrine figges, to wit, growing upon the Sycomore. Likewiſe a wine is made of the fruit in Syria, called Siliquæ; as alſo of peares and all kind of apples. As for the wine of Pomegranates, the Greekes name it Rhoïtes: beſides the fruit of the Corneil or wild Cherrie-tree; Medlars, Cerviſes, drie Mulberries, and Pine-nuts, doe yeeld ſeverall ſorts of wines. As for theſe Pine-nuts, they muſt lie ſteeped in new wines before the wine be preſſed out of them. The reſt
B all be pleaſant enough of themſelves, and will ſerve alone for to make wines. The manner of making Myrtle wine (according to the receit and preſcription of *Cato*) wee will declare ſoone hereafter. For the Greekes have another way of their owne, to wit, when they have ſodden in white Muſt or new wine, the tender braunches of the Myrtle, togither with the leaves, and then ſtamped the ſame, they put a pound thereof in three gallons more of Muſt, and cauſe it to boile untill ſuch time as a third part of the wine be conſumed. Now that which is made after the ſame manner of the wild Myrtle-berries, they call Myrtidanum; and this will colour and ſtaine ones hands blacke.

Furthermore, the hearbs of the garden doe affourd us many wines, namely Radiſh, Sparage, Savorie, and Majoran, Origan, Smallach ſeed, Southernwood, wild Mints, Rue, Nep or
C Calaminth, running Thyme, and Horehound. To make theſe wines, take of the hearbs aboveſaid, two handfuls, and when they be ſtamped, put them into a little barrell of new wine containing twelve or thirteene gallons, togither with a wine quart of Cuit ſodden to the thirds, and a pint of ſea water. But for the wine of Navewes, you muſt take eleven drams of them, and two quarts of new wine, and ſo put them togither in manner aforeſaid. In like ſort alſo the wine Squilliticum is made of the the root of Scilla, or the ſea Onion.

To proceed unto wines made of flowres, you have firſt and foremoſt wine Roſat, after this manner: Take the weight of fortie deniers [*i.* eight ounces] of Roſe-leaves well ſtamped, put them into a linnen cloth, togither with a little weight, that they may ſettle downward and not
D flote aloft; let them hang thus in twentie Sextars [*i.* three gallons] and two wine quarts of Muſt; keepe the veſſell cloſe ſtopped in any caſe for three moneths, then open it and ſtraine the ſaid floures unto the liquor. In like manner is there a wine made of the Celtick Spikenard, as alſo of the Nard-ſavage. I find alſo, that they uſe to make a kind of ſpiced wine or Ipocras, not for ſweet perfumes and ointments onely, but alſo for to drinke. At firſt (as I have ſhewed) they made theſe aromaticall wines with myrrhe only, but ſoone after they added thereto Nard Celtick, ſweet Calamus, and Aſpalathus: either ſlicing theſe drugs, or putting them by gobbets into new Muſt or ſome dulcet wine. Some aromatize their wine with Calamus, Squinanth, Coſtus, Spikenard,
E Amomum, Caſia, Cinamon, Saffron, Dates, and Azara-bacca, put thereto in like manner by gobbets. Others take Spikenard and Malabathrum, of each halfe a pound to two gallons of new wine. Much after the ſame manner we ſpice our wines now adaies alſo, but that we adde pepper and honey thereto: which ſome call Condite, others Pepper-wines. Moreover, there is deviſed a wine called Nectarites, made of Elecampane, named by ſome Helenium, of others Medica, Symphyton, Idæa, Oreſtion: and there be alſo that tearme this hearb Nectarea. Now the order of it, is to take of the root fortie drams to ſix Sextars of Muſt or new wine, and hang it in a cloth togither with a weight, in manner aboveſaid. Moreover, there be wines made of other hearbs, to wit of Wormwood, in this ſort: Take of Ponticke wormwood one pound, ſeeth it in fortie Sextars [about ſix gallons and a halfe] of new wine, untill a third part bee conſumed: or without boiling, put certaine handfuls or bunches thereof into a veſſell of wine, and ſo let it lye
F infuſed. After the ſame ſort is Hyſſope wine made, to wit, of three ounces (which is a quarter of a pound) of Cilician Hyſſope caſt whole as it is into two gallons of Muſt, and ſo let them worke togither: or elſe ſtampe the Hyſſope, and ſo put it into wine: but both theſe wines are made another manner of way, namely, by ſowing or ſetting Wormwood and Hyſſope at the verie root of the vine-plant: for ſo *Cato* teacheth us to make Ellebore wine, of blacke Ellebore or Bearefoot growing at the vine root. And in like manner alſo is made the Scammonite wine.

A wonderfull nature and propertie that these vines have, To draw and sucke into them the very taſt of other hearbs and plants that are set neare unto them: for even so all the grapes about Padua have a rellish of the Willowes and Osiers that grow there in the marish grounds. In this wise the men of Thasos doe plant and sow either Ellebore or wild Coucumber, or els Scammonea, about their vines, to make thereof their devilish wine Pthorium, so called, because it causeth a slip and procureth untimely birth. Of more hearbs besides, there bee other wines made: the vertues of which hearbs, we will set downe elsewhere in place convenient: and namely, of Stœchos, the root of Gentian, of Tragoriganum, of Dictamum, Asarabacca, of Daucus or yellow Carot, Sauge, Panace, Acorus or Galangal, Conyza or Cunilago, Thyme, Mandragoras, and Squinanth. More such wines there were yet, which the Greeks called Scyzinum, Iræomelis, and Lectispagites; but as they be growne now out of use, so the manner of making is unknowne.

As touching wines made of trees and shrubs, their manner was to seeth the berries or the greene wood of both the Cedars, the Cypresse, the Bay, Iuniper, Terebinth, Pine, Calamus, and Lentiske, in new wine. In like manner, the very substance of Chamelæa, Chamæpithys, and Germander. Last of all, the flowers also of the said plants serve to make wines, namely by putting in to a gallon of new wine in the vat, the weight of ten deniers or drams of the flowers.

Chap. xvii.

Of Hydromel, and Oxymel: [i. honyed water, and honyed vinegre.]

THere is a wine called Hydromel, made of water and honey onely: but to have it the bettet, some doe prescribe raine water, and the same kept five yeeres for that purpose. Others who are more wise and skilfull herein, doe take raine water newly falne, and presently seeth it untill a third part be boiled away; then they put thereto a third part also of old hony in proportion to it: and so let them stand togither in the Sunne for fortie daies togither, from the rising of the Dog-starre. Others, after they have remained thus mingled and incorporate togither ten daies, put it up and reserve it close stopped for their use; and this is called Hydromel: which when it is come to some age, hath the very taſt of wine: and no place affourdeth better than Phrygia.

Moreover, vinegre was wont to be tempered with honey, [See how curious men have been to trie conclusions in every thing!] which they called Oxymel, and that in this manner: *Recipe*, of honey, ten pounds or pints; of old vinegre, five pints; of sea salt, one pound; of raine water, five Sextares [i. a gallon within one quart:] Boile them all togither at a soft fire, untill they have had ten plawes or waulmes: which done, poure them out of one vessell into another, and so let the liquor stand & settle a long time, untill it be stale. All these wines and compositions thus brued, *Themison* (an Author highly renowmed) hath condemned and forbidden expressely to be used. And to say a very truth, it seemeth that the use of them was never but in case of necessitie: unlesse a man would beleeve and say, that Ipocras, spiced wines, and those that be compounded of ointments, are Natures worke; or that shee brought foorth plants and trees to no other end, but that men should drinke them downe the throat. Howbeit, the knowledge surely of such experiments, be pleasant and delectable unto men of great wit and high conceit, whose noble spirits cannot be at rest, but ever inventive and searching into all secrets. Now to conclude this point, certaine it is and past all question, that none of all these compositions (unlesse it be those which come to their perfection by age and long time) will last one yeere full out: nay most of them will not keepe good one moneth to an end.

Chap. xviii.

Certaine straunge and wonderfull kinds of wine.

WIne also hath prodigious and miraculous effects: for (by report) in Arabia there is a wine made, which being drunke will cause barrain women to beare children; and contrariwise drive men into madnes. But in Achaia principally about Carynia, the wine maketh women fall into untimely travell: nay if a woman great with child doe eat but the very grapes, they will slip the fruit of their wombe before their time: and yet both grape and wine differ not in taſt from others. They that drinke the wine comming from the cape of Trœzen, are thought unable for generation. It is reported, that the Thasiens doe make two kinds of wine of

contrary

contrary operations; the one procureth ſleepe, the other cauſeth watching. Among them there is a vine called Theriace, the grape whereof, as alſo the wine, cureth the ſtings and biting of ſerpents, as it were a moſt eſpeciall Treacle. As for the vine Libanios, it carrieth the odor and ſmell of Frankincenſe, and therefore is uſed in ſacrifices to the gods. But contrariwiſe another named Aſpendios, is utterly condemned for that purpoſe, and no wine thereof is employed at the altar: they ſay alſo, that no Foule will touch the grapes thereof. There is a kind of grape in Ægypt, which they call Thaſia, exceeding ſweet it is, and looſeth the bellie. But contrariwiſe there be in Lycia, that bind as much and cauſe coſtiveneſſe. The grapes Ecbolides in Ægypt, if they bee eaten, cauſe women with child to be delivered before their time. Some wines there be, that as they lie in the verie cellar, will turne and proove ſower about the riſing of the Dog-ſtarre; but afterwards will recover their verdure, and become quick and freſh againe. In like manner there be wines, that upon the ſea will chaunge: howbeit the agitation thereof, cauſeth thoſe wines that endure it to the end, to ſeeme twice as old as they be indeed.

Chap. xix.

What Wines they be that may not be uſed in Sacrifices: and what waies there are to ſophiſticate new wines.

FOraſmuch as our life ſtandeth much upon religion and divine ſervice, we are to underſtand; That it is held unlawful to offer unto the gods before ſacrifice, the wine of any vine that hath not been cut and pruned; or that hath been ſmitten and blaſted with lightning; or ſtanding neare to a jebbit or tree whereon a man hath hanged dead; or the grapes whereof have been troden by men whoſe leggs or feet have been wounded; neither is that wine allowable for this purpoſe, which hath been preſſed and run from the refuſe of grape-ſtones and skins once bruiſed and cruſhed in the preſſe; or laſt of all, if the grapes have been filed by any ordure or dung falne from above thereupon. Moreover, Greeke wines are rejected from this holy uſe, becauſe they have water in them. Furthermore the vine it ſelfe is holden good to be eaten, namely, when the burgens and tendrils bee firſt ſodden, and afterwards preſerved and kept in vinegre, brine, or pickle. Over and beſides, it were very meet and convenient to ſpeake alſo concerning the manner of preparing and ordering wine, ſeeing that the Greekes have travailed in that point ſeverally, and reduced the rules thereto belonging, into the forme of an Art; and namely, *Euphronius*, *Ariſtomachus*, *Contades*, and *Hiceſius*, are therein great profeſſors. The Africans uſe to mitigate and allay the tartneſſe of their wines with plaſtre, yea and in ſome parts of their countrey, with lime. The Greeks contrariwiſe doe fortifie and quicken them with clay, with powder of marble, with ſalt, or ſea water. And in ſome places of Italy, they uſe (to the ſame effect) the ſhavings and ſcrapings of ſtone-pitch. Alſo it is an ordinarie thing in Italy and the provinces thereto confining, for to condite their new wines and to ſeaſon them with roſin: yea and in ſome places they mingle therewith the lees of other old wine or vinegre. Oftentimes alſo they make ſlibber-ſauces of it ſelfe without any other mixture; namely, when they boile new wine ſufficiently to the proportion of the ſtrength, untill the hardneſſe do evaporate, and that it wax mild and ſweet: but being thus ordered, it will not laſt (they ſay) above one yeare. In ſome countries they uſe to ſeeth their new wine to the conſumption of a third part, and make it cuit, with which they are wont to delay the ſharpneſſe and ſtrength of other wines, and make them pleaſant. But both in this kind of wine and in all others, the veſſels ought to be prepared for the purpoſe, and ſeaſoned with pitch: the treatiſe of which, we will put off unto the next booke, where wee purpoſe to treat thereof, and the manner of making it.

Chap. xx.

Of divers kinds of Pitch and Roſins. The manner of the ſeaſoning and confecture of new Wines. Alſo of Vinegre and Salt.

AMong trees that yeeld from them a liquid ſubſtance, ſome there be in the Eaſt countries, and others in Europe, which ingender Pitch and Roſin. Aſia likewiſe between both, hath of either ſide of it, ſome ſuch trees. As for the Eaſt, the Terebinths put out Turpentine, the beſt and cleereſt Roſin of all others: next to them, the Lentiskes alſo have their Roſin, which

they call Maſtick. After which, the Cipreſſe bringeth forth a third roſin, but it is of a moſt ſharp and biting taſt. All theſe trees (I ſay) carie a roſin only, and the ſame thin and liquid: but the Cedar ſendeth out a thicke ſubſtance, and good to make pitch and tarre. As for the roſin or gum Arabicke, it is white of colour, ſtrong in ſmell, untoward & troubleſome to him that ſhall boile it. That of Iurie is harder, yea, and of a ſtronger ſavour than Turpentine. The Syriacke gum reſembleth the honie of Athens. The Cyprian excelleth all others: of a fleſhie ſubſtance it is, and like in colour to honie. The Colophonian is deeper of colour, and reddiſh: beat it to pouder in a morter, it proveth white: but it carieth a ſtrong ſmell with it; which is the reaſon, that the perfumers and makers of ointments have no uſe thereof. As for that which the Pitch trees of Aſia doe yeeld, it is paſſing white, and the Greekes call it Spagas. All roſins generally will diſſolve in oile. Some thinke verily, that potters clay will likewiſe doe the ſame. But I am abaſhed and aſhamed to report, how in theſe daies the ſame pitch whereof we ſpeak, ſhould be in ſo great account as it is, for making of pitch plaiſters, to fetch off the haire of mens bodies, and all to make them more ſmooth and effeminate. Howbeit, the manner of ſeaſoning new Muſt therewith (that when it is perfect wine it may ſmell of pitch, and bite at the tongues end) is to beſtrew it with the pouder of pitch at the firſt working, the heat whereof is commonly paſt and gone in nine daies. And ſome thinke, that the wine will bee the ſtronger, if the raw and greene flower of the roſin, as it iſſueth freſh out of the tree, bee put therein; for it will quicken a ſmall and weake wine. Now this mixture and medicine of wine [called Crapula] made thus of roſin, hath contrarie effects: for if the wine be over-headie and ſtrong, it allaieth and mortifieth the hurtfull force thereof: but if it be too weake, or drinke dead and flat, it reviveth againe, and giveth it a ſtrong taſt. In Liguria, and principally along the Po, they uſe to ſeaſon their wines, and bring them all to their ſeverall perfections in this manner. If the wine when it is new, be mightie and ſtrong, they put in the more of this medicine or confection called Crapula: if it be mild and ſmall, then the leſſe goes into it: and keeping this gage with their hand, they make both good. Some would have one wine brued with another, the weaker with the ſtronger, and ſo (forſooth) there muſt needs ariſe a good temperature of both together: and verily there is not a thing in the world againe, which hath in the nature thereof ſo great varietie.

In ſome countries, if new wine worke of it ſelfe a ſecond time, it is thought to bee a fault and meanes to corrupt it: and indeed, upon ſuch a chaunce and unhappie accident it looſeth the verdure and quicke taſt: whereupon it getteth the name of Vappa, and is cleane turned to bee dead or ſoure: in which regard alſo, we give a man that name by way of ſcorne and reproch, calling him Vappa, when he is heartleſſe, void of reaſon and underſtanding. If it were vinegre indeed, it were another matter: for ſurely although wine degenerat into it by way of corruption and putrifaction, yet a vertue and force it hath, good for many ſpeciall uſes, and without which it were not poſſible to live ſo delicately at our table as we doe. Moreover, the world is ſo much given to keepe a bruing, tempering, and medicining of wines, that in ſome places they ſophiſticate them with aſhes, as it were with plaiſter: in other, they fortifie, recover, and make them again by ſuch deviſes as are before ſpecified. But to this purpoſe they take the aſhes to chuſe, of vine cuttings, or of the oke wood, before any other. And forſooth if there be occaſion to occupie ſea-water for this buſines, they preſcribe them to fetch it far from land in the deep ſea; & kept beſides from mid March or the ſpring Æquinox, or at leaſtwiſe from mid-Iune or ſummer ſunne-ſtead; and drawne in the night ſeaſon, and when the North wind doth blow: but if it bee gotten neare the time of vintage, then it ought to be well boiled before it will ſerve the turn. As for the pitch in Italie, that of Brutium or Calabria is reputed for the beſt, to trim thoſe veſſels which are to keep wine. There is made of the roſin of the tree Picea (as alſo in Spain there commeth from the wild Pines) a certain pitch, which of all other is worſt: for the roſin of thoſe trees is bitter, drie, and of a ſtrong ſavor. The difference and ſundrie kinds of pitch, as alſo the manner of making the ſame, we will ſet down in the booke next following, in the treatiſe of wild & ſavage trees. The faults & imperfections of pitch, over and beſides thoſe even now rehearſed (to wit, bitterneſſe, drineſſe, & ſtrong ſent) are knowne by the ſoureneſſe, by the ſtinking ſmoke, and the very aduſtion thereof. But yee ſhall know good pitch by theſe experiments, If the peeces broken from it doe ſhine, if betweene the teeth it relent and be clammie like glew, and have a pleaſant ſharpeneſſe and ſoure taſt withall of the vinegre. In Aſia the pitch is thought beſt which commeth of the trees in mount Ida. The Greeks eſteem the trees of the hill Pieria cheefe for this purpoſe: and *Virgil* commendeth that of Narycia before all.

But

But to returne againe to our burning and ſophiſtication of wines, they that would ſeeme to be cunninger, or at leaſtwiſe more curious than their fellowes, doe mingle therewith blacke Maſticke, which is engendred in Pontus, and is like to Bitumen; and thereto adde the root of Iris or the flower de Luce, and oile. For this is found by experience, That if the veſſels be ſered with wax, the wines therein will not hold, but turne ſoure quickly. Moreover, we daily ſee, that better it is to put up wine into thoſe veſſels, wherein vinegre hath been kept afore, than into ſuch as had dulcet or honied wine. *Cato* ſetteth down a receit to trim and concinnate wine (for that is the very tearm which he uſeth) in this manner: Take of lie aſhes ſodden with cuit boiled to the halfe, one fortieth part; temper it with a pound and a halfe of peniroiall, or ſalt, and otherwhiles with marble braied and beaten into pouder among. Hee maketh mention alſo of brimſtone, but roſin hee nameth with the laſt. But above all he willeth to refreſh & renue the wine when it now beginneth to come unto maturitie & perfection, with new wine which he calleth Tortivum; & I take it, that he meaneth that which ran laſt out of the wine-preſſe: which hee preſcribeth alſo to bee put unto new wines for to get them a freſher colour, as the very tincture of wine: and ſo it will be alſo of a more fattie ſubſtance, and goe downe more glib and merrily. See, ſee, how many deviſes of medicines and ſlibber-ſauces the poore wine is forced to endure, and all to pleaſe our pallat, our eie, and other ſences: and yet ywis we marvell that it is ſo hurtfull to our bodies. Well, would you have an experiment to know when wine is going, or enclining to be dead and ſoure? dip therein a thin plate of lead; if it chaunge colour, take it for a ſigne, that it is in the way of decaying. Of all liquors, wine hath this propertie to vinew, to pall, and to change into vinegre. But a thouſand medicines it doth affoord, and bookes of Phyſicke are full thereof. Moreover, wine lees being dried, will ſerve as a match to keepe fire: and without any other fewell to feed it, yee ſhall have it burne and flame of it ſelfe. The aſhes thereof is of the nature of Nitre, and hath the ſame vertues: and in this regard ſomewhat more, for that it is found to be more fattie and uncteous.

Chap. xxi.

Of wine-cellars.

NOw when wine is made and tunned up in manner aforeſaid, there is as great difference and diverſitie in the beſtowing of it in cellars. They of Piemont about the Alpes, doe put up their wines in woodden barrels, bound well with hoopes, for warmth: and moreover, if the winter be very cold, they make fires in their cellars or butteries, to keep them for being frozen. I will tell you a ſtrange wonder, yet true and to be verified, not by heareſay but plain eieſight. There were ſeene upon a time whole heapes and huge lumpes of wine congealed into ice, by occaſion that the hoopes of the hogſheads burſt that contained the wine: and this was held for a prodigious token. For indeed wine of it owne nature will not congeale and freeze, onely it will looſe the ſtrength, and become appalled in extremitie of cold. In warmer climates and more temperate, they fill their wines into great ſtands and ſteanes of earth, which they ſet into the ground, either over the head all whole, or els by halfe; deeper or ſhallower, according to the ſituation and temperature of the region. Likewiſe they give the wine open aire in ſome places: whereas in other
E they keepe it cloſe within houſe in tavernes and cellars. And thereto belong theſe and ſuch like rules. Firſt, that one ſide of the wine-cellar, or at leaſtwiſe the windowes, ought to ſtand open to the North, or to the Eaſt in any wiſe, where the Sunne riſeth at the time of the Æquinoctiall. *Item*, that there be no muckhils nor privies neare: no roots of trees, nor any thing of a ſtrong and ſtinking ſavor: for that wine is of this nature, to draw any ſmell very quickly into it: and above all, Fig-trees (as well the wild as the tame) be hurtfull to wine-cellars. *Item*, as touching the order of placing the wine veſſels, they ought to ſtand a pretie diſtance one from another: for feare of contagion, for that wine is alwaies moſt apt to catch infection very ſoone. Moreover, it mattereth much of what proportion and faſhion the pipes, tubs, and ſuch veſſels be made. Thoſe with great bellies and wide mouths, are not ſo good. Alſo they muſt bee nealed with pitch, preſently upon
F the riſing of the dog ſtarre: afterwards douſed and waſhed all over either in the ſea or els ſalt water, then to bee ſeaſoned and ſtrewed with vine aſhes or cley: and when they bee ſcoured, they ought to ſweeten them with a perfume of Myrrhe; which were good to be done alſo unto the very cellars oftentimes. Furthermore, if the wines be weake and ſmall, they had need to be kept in tubs and hogſheads, let downe within the ground: but the ſtrong and mightie wines may lie above

ground in the open aire. Provided alway, that wine veſſels bee never filled top full: but the void part that is left, and ſtandeth above the wine, would be throughly dight with thicke wine made of withered grapes, or ſodden wine to the halfe, and ſaffron mingled withall, yea, and old pitch, together with cuit. Thus alſo ought the lids and bungs of the veſſels to bee ordered, with an addition beſides of maſticke and pitch. In the deepe of Winter they muſt not be unſtopped and opened in any caſe, unleſſe the weather bee faire and cleare. Neither when the wind is Southerly, or the Moone in the full. This alſo is to be noted, that the flower or mantle which the wine caſteth up to the top, is good when it is white: if it be red, it is a very bad ſigne, unleſſe the wine it ſelfe bee of that colour. Moreover, if the veſſels bee hote, or the lids doe ſweat, it is no good ſigne. Note alſo, that the wine which ſoone beginneth to mantle and caſt up a floure incontinently, or to yeeld another ſmell than the owne, will not continue long good. As for the cuits, whether they be ſodden to the halfe or the thirds, they ought to be boiled & made when the skie is without a Moon, that is to ſay, in the chaunge, and upon no day els. Moreover, the decoction muſt be in leads, and not in coppers; with walnuts among to receive all the ſmoke, which otherwiſe might infect the cuit. In Campaine they let their beſt wines lie abroad in veſſels, even in the open aire, to take the Sunne, the Moone, raine, and wind, and all weathers that come: and this is thought to bee beſt for them.

Chap. xxii.

Of avoiding Drunkenneſſe.

IF a man marke and conſider well the courſe of our life, we are in no one thing more buſie and curious, nor take greater pains, than about wine: as if Nature had not given to man the liquor of water, which of all others is the moſt holeſome drinke, and wherwith all other creatures are well contented. But we thinking it not ſufficient to take wine our ſelves, give it alſo to our Horſes, Mules, and labouring beaſts, and force them againſt Nature to drinke it. Beſides, ſuch paines, ſo much labour, ſo great coſt and charges we are at, to have it; ſuch delight and pleaſure wee take in it; that many of us thinke, they are borne to nothing els, and can skill of no other contentment in this life: notwithſtanding, when all is done, it tranſporteth and carrieth away the right wit and mind of man, it cauſeth furie and rage, and induceth, nay, it caſteth headlong as many as are given thereto, into a thouſand vices & miſdemeanors. And yet forſooth, to the end that we might take the more cups, and poure it downe the throat more luſtily, we let it run through a ſtrainer, for to abate and gueld (as it were) the force thereof: yea, and other deviſes there be to whet our appetite thereto, and cauſe us to quaffe more freely. Nay, to draw on their drinke, men are not afraid to make poiſons, whiles ſome take hemlocke before they ſit down, becauſe they muſt drink perforce then, or elſe die for it: others, the pouder of the *pumiſh ſtone, & ſuch like ſtuffe, which I am abaſhed to rehearſe and teach thoſe that bee ignorant of ſuch leaudneſſe. And yet wee ſee theſe that bee the ſtouteſt and moſt redoubted drinkers, even thoſe that take themſelves moſt ſecured of daunger, to lie ſweating ſo long in the baines and brothel-houſes for to concoct their ſurfet of wine, that otherwhiles they are caried forth dead for their labour. Yee ſhall have ſome of them againe when they have been in the hot houſe, not to ſtay ſo long as they may recover their beds, no not ſo much as to put on their ſhirts: but preſently in the place, all naked as they are, puffing and labouring ſtill for wind, catch up great cans and huge tankards of wine (to ſhew what luſtie and valiant champions they bee) ſet them one after another to their mouth, poure the wine downe the throat without more adoe, that they might caſt it up againe, and ſo take more in the place; vomiting and revomiting twice or thrice together that which they have drunke, and ſtill make quarrell to the pot: as if they had beene borne into this world for no other end but to ſpill and marre good wine: or, as if there were no way els to ſpend & waſt the ſame, but through mans bodie. And to this purpoſe, were taken up at Rome theſe forraine exerciſes, of vaulting and dancing the Moriske; from hence came the tumbling of wraſtlers in the duſt and mire together; for this, they ſhew their broad breaſts, beare up their heads, and carie their neckes farre backe. In all which geſticulations, what doe they elſe but profeſſe that they ſeeke means to procure thirſt, and take occaſion to drinke? But come now to their pots that they uſe to quaffe and drinke out of: are there not graven in them faire pourtraits thinke you of adulteries? as if drunkenneſſe it ſelfe were not ſufficient to kindle the heat of luſt, to pricke the fleſh, and to teach them wantonneſſe. Thus is wine drunke out of libidinous cups: and more than that, he that can quaffe beſt and play the drun-

*Vide lib. 36. cap. 21.

A drunkard moſt, ſhall have the greateſt reward. But what ſhall we ſay to thoſe (would a man think it?) that hire one to eat alſo as much as hee can drinke, and upon that condition covenant to yeeld him the price for his wine drinking, and not otherwiſe. Yee ſhall have another that will enjoyne himſelfe to drinke every denier that hee hath woon at dice. Now when they are come to that once, and be throughly whitled, then ſhall ye have them caſt their wanton eyes upon mens wives; then fall they to court faire dames and ladies, and openly bewray their folly even before their jealous and ſterne husbands; then (I ſay) the ſecrets of the heart are opened & laid abroad. Some ye ſhall have in the mids of their cups, make their wills, even at the very board as they ſit: others againe caſt out bloudie and deadly ſpeeches at randon, and cannot hold but blurt out thoſe words which afterwards they eat againe with the ſwords point: for thus many a man by a
B laviſh tongue in his wine, hath come by his death and had his throat cut. And verily the world is now growne to this paſſe, That whatſoever a man ſaith in his cups, it is held for ſooth; as if Truth were the daughter of Wine. But ſay they eſcape theſe daungers: certes ſpeed they never ſo well, the beſt of them all never ſeeth the ſun-riſing, ſo drowſie and ſleepie they are in bed everie morning; neither live they to be old men, but die in the ſtrength of their youth. Hence commeth it, that ſome of them looke pale, with a paire of flaggie blabd cheekes; others have bleared and ſore eyes: and there be of them that ſhake ſo with their hands, that they cannot hold a full cup, but ſhed and poure it down the floore. Generally they all dreame fearfully (which is the very beginning of their hell in this life) or els have reſtleſſe nights: and finally, if they chaunce to ſleepe (for a due guerdon and reward of their drunkenneſſe) they are deluded with imaginary
C conceits of *Venus* delights, defiled with filthie and abominable pollutions: and thus both ſleeping and waking they ſinne with pleaſure. Well, what becomes of them the morrow after? they belch ſowre, their breath ſtinketh of the barrell, and telleth them what they did over night; otherwiſe they forget what either they did or ſaid, they remember no more, than if their memorie were utterly extinct and dead. And yet our jollie drunkards give out and ſay, That they alone enjoy this life, and rob other men of it. But who ſeeth not, that ordinarily they looſe not onely the yeſterday paſt, but the morrow to come? In the time of *Tiberius Claudius* the Emperour, about fortie years ſince, certain out-landiſh Phyſicians and Monte-banks, who would ſeem to ſet themſelves out by ſome ſtraunge novelties of their owne, and ſo get a name, brought up at Rome a new deviſe and order, to drinke faſting; and preſcribed folke to take a good heartie draught of wine before meat, and to lay that foundation of their dinner. Of all nations, the Parthians would have the glory for this goodly vertue of wine-bibbing: and among the Greekes, *Alcibiades* indeed deſerved the beſt game for this worthy feat. But here with us at Rome *Novellius Torquatus* a Millanois, wan the name from all Romans & Italians both. This Lombard had gone through all honourable degrees of dignitie in Rome; he had been Pretor, and attained to the place of a Proconſull. In all theſe offices of ſtate he woon no great name: but for drinking in the preſence of *Tiberius*, three gallons of wine at one draught and before he tooke his breath againe, he was dubbed knight by the ſurname of *Tricongius*, as one would ſay, *The three gallon knight: and the Emperour, ſterne, ſevere, and cruell otherwiſe though he was, now in his old age (for in his youthfull daies hee was given overmuch to *drinking of wine) would delight to behold this renowmed and worthie knight, with great wonder and admiration. For the like rare gift and commendable qualitie, men thinke verily that *C. Piſo* firſt riſe: and afterwards was advanced to the Provoſtſhip of the citie of Rome, by the ſaid *Tiberius*: and namely, for that in his court being now Emperor, he ſat two daies and two nights drinking continually, and never ſtirred foot from the bourd. And verily *Druſus Cæſar* (by report) in nothing more reſembled his father *Tiberius*, than in taking his drinke. But to return again to noble *Torquatus*, herein conſiſted his excellencie, That he did it according to art [for this you muſt take withall, there is an art of Drinking, grounded upon certaine rules & precepts.] *Torquatus* (I ſay) drank he never ſo much, was not known at any time to falter in his tongue, never eaſed himſelfe by vomiting, never let it go the other way under bourd: how late ſoever he ſat up at the wine overnight, he would be ſure to relieve the morning watch & ſentinell. He drunke moſt of any man at one entire draught before the pot went from his head; and for ſmaller draughts beſides, he went beyond all other in number; his wind he never tooke while the cup was at his mouth, but juſtly obſerved the rule of drinking with one breath; he was not known to ſpit for all this: and to conclude, he would not leave a drop behind in the cup, not ſo much as would daſh againſt the pavement, & make the leaſt ſound to be heard: a ſpeciall point & preciſe law

*not The thrice-gallant knight.

* Whereupon he was called *Biberius Mero*, for *Tiberius Nero*.

to

to prevent the deceit of thoſe that drinke for a wager. A ſingular glorie no doubt in him, and a rare felicitie. *Tergilla* challenged *M. Cicero* the younger, ſonne to that *M. Cicero* the famous Oratour, and reproched him to his face, that ordinarily he drunke two gallons at ones: and that one time above the reſt when he was drunke, he flung a pot at *M. Agrippa* his head. And truly this is one of the fruits and feats of drunkenneſſe. But blame not young *Cicero*, if in this point yet hee deſired to ſurmount him that ſlew his father, *M. Antonius* I meane; for he before that time ſtrained himſelfe, and ſtrove to win the beſt game in this feat, making profeſſion thereof, as may appeare by a booke that he compiled and ſet forth with this title, *Of his owne drunkenneſſe*: wherein he was not aſhamed to avow and juſtifie his exceſſe and enormities that way: and thereby approved (as I take it) under pretence and colour of his drunkenneſſe, all thoſe outrages of his, all thoſe miſeries and calamities that hee brought upon the whole world. This treatiſe he vomited and ſpued out a little before the battell of Actium, wherein he was defeated: whereby it may appeare very plainely, that as hee was drunken before with the bloud of citizens, ſo ſtill hee was the more bloud-thirſtie. For this is a propertie that neceſſarily followeth this vice, That the more a man drinketh, the more he may, and is alwaies drie. And herein ſpake to good purpoſe a certaine Embaſſadour of the Scythians, ſaying, That the Parthians the more they drunke, they thirſtier they were.

As touching the nations in the Weſt part of the world, they have their drinkes alſo by themſelves made of *corne ſteeped in water, whereof they will drinke to the utterance, and be drunke: and namely in Spaine and Fraunce, where the manner of making the ſame is all one, howſoever they have *divers names. And in Spain they have deviſed means that theſe drinks (Ale or Beere) will abide age, and continue ſtale. In Ægypt likewiſe they have invented ſuch kind of drinks made of corne: ſo that no part or corner of the world there is, but drunkenneſſe reigneth. And verily theſe liquors howſoever they bee named, they uſe to drinke entire as they bee, and made of the very ſtrength of Malt: never delaying the ſame with water, as we doe wines. But it may bee ſaid, That Nature hath endowed and enriched thoſe countries with abundance of corn, and therfore they may well doe it. Oh how induſtrious we are to maintaine our vices! There is a deviſe found, (would ever any man have thought it?) how water alſo ſhould make men drunke. Two liquours there be, moſt pleaſing and acceptable to mens bodies, Wine within, & Oile without. Both proceed from two ſpeciall trees, howbeit, of the twaine, Oile is neceſſarie, and Wine may be better ſpared. And verily, men have not been idle in the making of good Oile: howbeit, they have been more addicted and given to make Wines for drinke; as may appeare by this, that reckoning but the generall kinds thereof, a man may find 195 ſorts of wine: but if a man would ſubdivide and deſtribute thoſe heads into their braunches, hee ſhould meet almoſt with twice as many: but of Oiles there bee not ſo many kinds by farre. Whereof wee purpoſe to treat in the booke next following.

*i. Malt.

*Zythus and Curmi, Ale and Beere.

THE XV. BOOKE OF THE HISTORIE OF NATVRE, WRITTEN BY C. PLINIVS SECVNDVS.

Chap. I.

The natures of Trees that beare Fruit.

THere were no Olive trees grew in Italie, but upon the coaſt ſide, and that within fortie miles of the ſea, about the 440 yeare after the foundation of the citie of Rome; if it bee true that *Theophraſtus* ſaith, who was one of the moſt famous and renowmed Authors among the Greekes. *Feneſtella* writeth moreover, and affirmeth, That during the reign of *Tarquinius Priſcus* (which was much about the 183 yeere from the foundation of the citie of Rome) there were no Olive trees at all to be found, either in Italie, Spaine, or Africk: whereas now at this day they are ſeene all Italie over, yea and bee come as farre as the regions beyond the Alpes, even into the mids and very heart of Fraunce and Spaine. Indeed, in the yeare after the foundation of Rome 505 (which was when *Appius Claudius*, the nephew of that great *Appius Claudius* ſurnamed The blind, and *L. Iunius* were Conſuls togither) a pound of the oyle was ſold for twelve aſſes: and not long after (namely, in the 680 yeere) *M. Seius* the ſonne of *Lucius* (one of the Ædiles-Curule for the time beeing) brought downe the market ſo well, that a man might have bought ten pound for one As; and at that price he ſerved the people of Rome thoughout all that yeere. Leſſe cauſe therefore a man hath to marveile hereat, who knoweth how not paſt 22 yeeres after that, (namely when *Cn. Pompeius* was the fourth time Conſull) Italy was able to furniſh other nations and provinces with oile of Olives. *Heſiodus* alſo (who was eſpecially addicted to the ſtudie of husbandrie, and of all things thought it moſt neceſſarie to be taught and publiſhed for the good of mankind) wrate thus much concerning the Olive, That never a man was knowne to that day for to have gathered the fruit of that Olive tree, which himſelfe had planted: ſo late of growth were thoſe trees in his time, and ſo ſlowly came they forward. But now adaies they come up of kernels and ſtones ſet in plots of ground for the purpoſe: and being tranſplanted againe, they beare Olives the ſecond yeare after. *Fabianus* ſaith, That Olives love not to grow either in the coldeſt or the hoteſt grounds.

Virgill hath ſet downe three kind of Olives, to wit, Orchitæ [*i.* the great round Olives:] Radij [*i.* the long Olives:] and thoſe which are called Pauſiæ. He ſaith moreover, That the Olive trees require no tending or dreſſing at all, and need neither the hooke to be pruned, nor the rake and harrow to be moulded, ne yet the ſpade to bee digged about. Doubtleſſe, the goodneſſe of the ſoile, and the temperature of the climat eſpecially, are very requiſite and much materiall alone, without farther helpe: howbeit they uſe to be cut and pruned, yea they love alſo to be ſcraped, poliſhed, and cleanſed betweene where the branches grow over-thick, even as well as vines, and at the ſame ſeaſon.

The time of gathering Olives enſueth preſently upon the vintage of grapes: but greater induſtrie and skill is required to the making and tempering of good oile, than about new wine: for ye ſhall have one & the ſelfeſame kind of Olive to yeeld a different juice, and divers oiles. Firſt and foremoſt, of the greene Olive and altogither unripe, there is drawne the Oile-olive; which hath of all other the beſt verdure, and in taſt excelleth the reſt: and of this oile, the firſt running that commeth from the preſſe, is moſt commended: and ſo by degrees better or worſe, as the

oile

oile is drawne before or after, out of the preſſe: or, according to a late invention, by treading them with mens feet in little paniers, and upon hardles made of ſmall and fine oſiers. This is a rule, The riper that the Olive is, the fatter will the oile bee, and more plentifull; but nothing ſo pleaſant in taſt. And therefore the beſt ſeaſon to gather Olives, both for goodneſſe and abundance of oile, is when they begin to ſhew blacke. And ſuch halfe-ripe Olives wee in Latine call Drupæ, & the Greekes Drypetæ. To conclude, it skilleth very much whether the berries ripe upon the tree, or mellow within their preſſe: alſo whether the tree bee watered, that is to ſay, the Olives hanging thereupon be drenched and refreſhed with ſprinckling water, or have no other moiſture than their owne, and that which they receive by dewes and raine from heaven.

Chap. ii.

Of oile.

OIle-Olive commeth to have a ranke and unpleaſant taſt if it be old kept and ſtale, contrarie to the nature of wine, which is the better for age. And the longeſt time that oile will continue good, is but one yeare. Wherein ſurely if a man would well conſider, hee may obſerve the great providence of Nature. For ſeeing that wines are made to ſerve for intemperance and drunkenneſſe, there is not that neceſſitie to drinke much thereof, and to ſpend them out of hand: and more than ſo, the daintie taſt that they have when they be ſtale, induceth men to lay them up and keepe them long. But contrariwiſe, ſhe would not have us make ſuch ſpare of oile: and therefore by reaſon of the generall uſe and need thereof, ſhe hath made it vulgar and common to all.

As touching this benefite and gift of Nature beſtowed upon mankind, Italie of all other nations in the world carieth the name for the goodneſſe thereof: but principally the territorie or countie of Venafrum, and namely, that quarter lying toward Licinia, which yeeldeth the oile called Licinianum: wherupon there be no Olives compatable to them of Licinia, both for to ſerve the perfumers, in regard of the pleaſant ſmell which that oile doth give, ſo appropriat unto their ointments; as alſo to furniſh the kitchin and the table (as they ſay that be fine-toothed, and have a delicate taſt:) which is the cauſe (I ſay) that this oile carieth the onely name. And yet theſe Olives of Licinia have this priviledge beſides, that birds love not to come near unto them. Next to theſe Licinian Olives, the queſtion is betweene them of Iſtria and Bætica, whether of them ſhould go away with the price for their goodneſſe? and hard it is to ſay, which is the better of the twaine. A third degree there is under thoſe two abovenamed, namely, of the Olives that come from all other provinces, ſetting aſide the fertile ſoile of that tract in Affricke, which yeeldeth ſo great increaſe of corne. For it ſhould ſeeme that Nature hath ſet it apart for graine onely, ſeeing it ſo fruitfull that way: and hath not ſo much envied it the benefite of wine and oile, which ſhee hath denied thoſe parts, as thought it ſufficient that they might glory, & have the name for their harveſts. As for other points belonging to Olives, men have erred and ben deceived very much: neither is there in any part concerning our life, to be found more confuſion, than is therein: as we will ſhew and declare hereafter.

Chap. iii.

The nature of the Olive berries: alſo, of young Olive plants.

THis fruit called the Olive, conſiſteth of a ſtone or kernill, of oile, a fleſhie ſubſtance, and the lees or dregs: now by theſe lees (called in Latine Amurca) I meane the bitter liquor of the grounds that the oile yeeldeth. It commeth of abundance of water: and therefore as in time of drought there is leaſt thereof, ſo in a rainie and waterie conſtitution, you ſhall have ſtore and plentie. As for the proper juice of the Olive, it is their oile: and the cheeſe is that which commeth of thoſe that are unripe, like as wee have ſhewed before, when wee treated of Omphacium, or the Olive verjuice. This oilie ſubſtance doth increaſe & augment within the Olive untill the riſing of the ſtar Arcturus, to wit, ſixteene daies before the Calends of October; after which time, their ſtones and carnous matter about them doe rather thrive. But marke, when there followeth a glut of raine and wet weather preſently upon a drie ſeaſon, the oile in them doth corrupt & turne all (well neare) into the trees abovеſaid, which may eaſily be perceived by the colour: for it cauſeth

ſeth the Olive berrie to looke blacke. And therfore when this blackneſſe beginneth to appeare, it is a ſign that they have ſomewhat (although very little) of the lees: but before that, they had none at all. And herein are men foulely deceived, taking this marke for the beginning of their ripeneſſe: which blacke hew indeed is a ſigne of their corruption, and betokeneth that then they are in the way to be ſtarke naught. They erre alſo in this, that they ſuppoſe an Olive the more growne it is in carnoſitie, to be the fuller of oile: whereas in very truth, all the good juice in them is converted then into the groſſe and corpulent ſubſtance thereof, and thereby alſo the ſtone and kernill come to bee big and maſſie: which is the cauſe, that they had need of watering at that time, moſt of all. Which being done by great paine and labour of man, or happening through raine and plentie of ſhewers; unleſſe there enſue a drie ſeaſon & faire weather to extenuate that groſſe ſubſtance into which the Olive had turned the foreſaid juice and humor, all the oile is conſumed and loſt. For it is heat and nothing els (as *Theophraſtus* ſaith) which engendreth oile: and therfore both about the preſſe at firſt, and alſo in the very garners where Olives be laid after, they uſe to keepe good fires, by that meanes to draw the more oile forth. A third default there is in oile, and that commeth of two much ſparing and niggardiſe: for ſome men there are, who being loth to be at coſt to plucke and gather Olives from the tree, wait ſtill and looke that they ſhould fall of themſelves. And ſuch folke as would ſeeme yet to keepe a meane herein, namely, to take ſome paines and be at a little coſt; beat and pell them downe with perches and poles: whereby they doe offer wrong to the poore trees, yea, and hinder themſelves not a little the yeare following, when they ſhall find how much it is out of their way, thus to breake their boughes and branches. Whereupon the law in old time provided well for this inconvenience, by an expreſſe inhibition to all gatherers of Olives, in theſe words, NO MAN SO HARDIE AS TO BREAKE, STRIKE, AND BEAT THE OLIVE TREE. But they that goe moſt warily and gently to worke, ſtand under the tree, and with ſome canes ſhake the boughs and branches therewith, or lightly ſmite them: but in no caſe let drive and lay at them either with full down-right or croſſe-blowes. And yet, as heedfull as they be in ſo doing, this good they get by ſtriking and knapping off the young ſhoots and ſprigs which ſhould beare the next year, that they have the trees carie fruit but once in two years for it. The like happeneth alſo, if a man ſtay till they fall of themſelves: for by ſticking on the tree beyond their due time, they rob the Olives to come after, of all their nutriment wherewith they ſhould be fed, and deteine the place likewiſe where they ſhould come forth and grow. An evident proofe hereof is this, That Olives unleſſe they be gathered before the ordinarie and yearely Weſterne winds doe blow, they gather heart againe upon the tree, and will not ſo eaſily fall as before. Men uſe therefore to gather the Pauſian Olives firſt after Autumne, which are fulleſt of carnoſitie, not ſo much by nature as by miſgovernment and diſorder; ſoone after, the round Orchitæ, which have plentie of oile; and then the Olives Radij: and theſe, for as much as they be moſt tender, & ſooneſt overcome with abundance of the lees (which we called before Amurca) are therby forced to fall. Howbeit, ſuch Olives as be thick skinned and hard; tough alſo & admitting no wet and raine (by which means they are the leaſt of all others) will abide on the tree untill March: and namely, the Licinian Olives, the Cominian, Contian, & Sergian, which the Sabins call Roiall: all which change not colour & look black before the foreſaid Weſterne wind bloweth, that is, about the ſixt day before the Ides of Februarie; for by that time folke think they begin to ripen. Now for as much as the beſt & moſt approved oile is made of them, it ſeemeth that reaſon alſo being conformable to this defect of theirs, juſtifieth & approveth the ſame in the end. And this is commonly received and held among them, that cold winters breed ſcarſitie and dearth: but full maturitie brings plentie, namely when they have leiſure to ripen upon the tree: howbeit this goodnes is not occaſioned by the time, but by the nature rather of thoſe kind of Olives, which bee long ere they turn into the foreſaid dregs Amurca. Men are likewiſe as much deceived in this, that when Olives be gathered, they keep them upon bourded floores in ſollars and garners, & will not preſſe them before they have ſweat: whereas, in truth, the longer they lie, the leſſe oile they yeeld, & the more dregs of lees. For by this meanes the ordinarie proportion they ſay is, to preſſe out of every Modius of Olives, not above ſixe pound of oile. But no man maketh any reckoning of the lees, how much it increaſeth in meaſure day by day, in one and the very ſame kind of Olives, the longer that they be kept ere they be preſſed. In one word, it is a common error ſetled every where, that men do think the abundance of oile is to be eſteemed according to the bignes of the Olives: conſidering that the plentie of oile conſiſteth not in the greatneſſe of the fruit: as may appear by thoſe which

of

of ſome are called Roiall, of others Majorinæ, and Phauliæ, which every man knoweth, are the biggeſt and faireſt Olives to ſee to, and yet otherwiſe have leaſt oile in them of any others. Likewiſe in Ægypt the Olives are moſt fleſhie & full of pulpe, howbeit, leaſt oileous. As for the countrie Decapolis of Syria, the Olives indeed be very ſmall there, & no bigger than Capers: yet commended they are for their carnoſitie. And for that cauſe, the Olives from the parts beyond ſea are preferred before the Italian, for goodneſſe of meat, and as better to be eaten; yet thoſe of Italie yeeld more oile. And even within Italie, the Picene and Sidicine Olives ſurpaſſe the reſt. For in truth, theſe are firſt confected and ſeaſoned with ſalt: or els (as all others) prepared and condite either with lees of oile, or wine-cuit. Some Olives there bee, which they ſuffer to ſwim alone as they be, in their own oile, without any helpe and addition of other things; and ſuch be called Colymbades. And the ſame they uſe otherwhiles to bruiſe and cleanſe from their ſtones, and then confect them with greene hearbs, which have ſome pleaſant & commendable taſt. Others there are, which being otherwiſe very greene and unripe, are preſently brought to maturitie, and made mellow, by lying infuſed and ſoking in hote ſcalding water. And a wonder it is to ſee, how Olives will drinke in a ſweet liquor, and how by that meanes they may be made toothſome, yea, and to carie the taſt of any thing that a man would have them. Among Olives there be alſo that are of colour purple, like to thoſe grapes which change colour when they begin to ripen. Moreover, beſides the abovenamed ſorts of Olives, there be ſome named Superbæ [*i.* prowd.] Alſo there are Olives to be found, which being dried by themſelves onely, are paſſing ſweet, yea, and more delicate than raiſins: marie theſe are very geaſon, and yet ſuch are in Affricke and about the citie Emerita in Portugall.

As touching the very oile it ſelfe, the way to preſerve it from being overfat and thicke, is with ſalt. If the barke of an Olive tree be ſlit and cut, it will receive the rellice and ſmell of any medicinable ſpice, and the oile thereof will ſeeme aromatized: otherwiſe pleaſant in taſt it is not, like as wine is: neither is there ſuch difference in ſo many kinds of Olives as there is in wine: for ſurely we cannot at the moſt obſerve above three degrees in the goodneſſe of oiles, namely, according to the firſt, ſecond, and third running out of the preſſe. Finally, the thinner that oile is, and the more ſubtile, the finer and daintier is the ſmell thereof: and yet the ſame ſent, in the very beſt of them all, continueth but a ſmall time.

Chap. iiii.

The nature of oile Olive.

THe propertie of Oile, is to warme the bodie, and to defend it againſt the injuries of cold: and yet a ſoveraigne thing it is to coole and mitigate the hote diſtemperature of the head. The Greekes, whom we may count the very fathers and foſters of all vices, have perverted the true and right uſe thereof, to ſerve for all exceſſe and ſuperfluitie: even as farre as to the common annointing of their wraſtlers with it, in their publicke place of exerciſe. Knowne it is for certaine, that the governours and wardens of thoſe places, have ſold the oile that hath been ſcraped from the bodies of the ſaid wraſtlers for 80 Seſterces at a time.

But the ſtately majeſtie of Rome contrariwiſe hath done ſo great honour to the Olive tree, that every yeare in Iulie, when the Ides come, they were wont to crowne their men of armes and gentlemen marching by their troups and ſquadrons in ſolemne wiſe, with chaplets of Olive; yea and the manner was of captaines likewiſe to enter ovant in petie triumphs into Rome, adorned with Olive coronets. The Athenians alſo honoured their conquerors with Olive guirlands. But generally the Greekes did ſet out their victors at the games of Olympia, with braunches of the wild-Olive.

Chap. v.

The manner how to order Olives.

NOw will I report the precepts and rules ſet downe by *Cato*, as touching Olives. His opinion is, that the greater long Olive Radius of Salentum, the big Orchites, the Pauſia, the Sergiana, Cominiana, and the Albicera, ſhould be planted in hote and fat grounds. Hee addeth moreover (as he was a man of ſingular dexteritie and prudent ſpirit) which of them in the neigh-

neighbour territories and places adjoyning, were taken for the beſt. As for the Licinian Olives, he ſaith, They would be planted in a weelie and cold hungrie ground: for if it be a fat ſoile and a hot, the oile will be corrupt and naught, and the very tree it ſelfe will in ſhort time be killed with overmuch fertilitie and bearing too great a burden. Moreover, they will put forth a red kind of moſſe, which eateth and conſumeth the tree. To conclude, his mind is, that Olive hort-yards ſhould be expoſed to the ſunne, yet ſo, as they regard the Weſt wind alſo in any caſe, for otherwiſe he commendeth them not.

Chap. vi.

How to keepe Olives, and the way to make oile of them.

Cato alloweth of no other means to keep and preſerve Olives (and ſpecially the great ones made like cullions, named thereupon Orchita, and the Pauſiæ) but either in brine and pickle when they are greene, or elſe among Lentiske braunches when they are bruiſed and broken. The beſt oile is made (ſaith he) of the greeneſt and ſowreſt Olives. Moreover, ſo ſoon as ever they be falne, they muſt be gathered from off the ground; and if they be fouled and berayed with the earth, they ought to be waſhed clean, and then laid to dry three daies at the moſt. Now if it fall out to be weather diſpoſed unto froſt, they ſhould be preſſed at foure daies end. He giveth order alſo, to beſtrew and ſprinkle them with ſalt: ſaying moreover, That if they be kept in boarded ſollars or garners, the oile will be both leſſe in quantitie, & worſe withall. So it will be alſo, if it be let lie long in the lees, or togither with the cake and grounds, when they be bruſed & beaten: for this is the very fleſhie and groſſe ſubſtance of the Olives, which cannot chuſe but breed filthy dregs. And therfore he ordaineth, that oftentimes in a day it ſhould be poured out of one veſſell into another, and ſo by ſetling clarified from the grounds; and then to put it up afterwards into pans and panchions of earth, or els into veſſels or kimnels of lead, for braſſe mettall will marre oile. All this ſhould be done within cloſe preſſes and rowmes, and thoſe kept ſhut, where no aire or wind may come in, that they might be as warme and hot as ſtouves. He forbiddeth alſo to cut any wood or fuell there, to maintain fire; for that the fire made of their ſtones & kernels, is moſt kindly of any other. To the end alſo that the grounds and lees ſhould be liquified and turne inro oile, even to the very laſt drop, the oile ſhould be let run out of thoſe veſſels or kimnels aforeſaid into a vat or ciſtern: for which purpoſe the veſſels are often to be cleanſed, and the oiſier paniers to be ſcoured with a ſpunge, that the oile might ſtand moſt pure and cleare. But afterward came up the deviſe to waſh Olives firſt in hot water, and then immediatly to put them whole as they are, into the preſſe; for by that means they ſquize forth lees and all: and then anon to bruſe and cruſh them in a mill, & ſo preſſe them in the end. Moreover, it is not thought good to preſſe the ſecond time above 100 Modij, which is the full proportion of one preſſure, & it is called Factus. That which after the mill commeth firſt, is named The floure of the oile, or the Mere-gout. Laſt of all, to preſſe 300 Modij, is thought to be foure mens worke ordinarily in one night and a day.

Chap. vii.

Of Oile artificiall.

IN *Cato* his time there was no artificiall Oiles, I meane, no other but that of the Olive; and therefore I ſuppoſe it was, that he made no mention thereof: but now adaies there bee many kinds. Firſt will we treat of thoſe that are made of trees, and principally before all the reſt, of the oile of the wild Olive: Thin it is, and much more bitter than that of the other gentle & true Olive, but good for medicines only.

Very like to it, is that which is made of Chamelæa, an herb or ſhrub growing in ſtonie places, to the heigth of a ſpan and no more, with leaves and berries reſembling thoſe of the wild Olive.

The next is that which commeth of Cici, or Ricinus, [*i.* Palma Chriſti] a plant which groweth plentifully in Ægypt, which ſome call Croto, others Trixis or wild Seſame; but long it hath not been there. In Spaine likewiſe this Ricinus is found of late to riſe ſodainly to the heigth of an Olive tree, bearing the ſtalke of Ferula or Fenell-geant, clad with leaves of the vine, and repleniſhed with ſeed reſembling the graines or kernels of ſmall and ſlender grapes, and of a pale colour withall: wee in Latine call it Ricinus, of the reſemblance that the ſeed hath to a ticke,

which is a vermin that annoieth ſheepe. For to gather an oile thereof, the manner is to ſeeth the ſeeds in water; the oile will ſwim aloft, and ſo it is ſcummed off. But in Ægypt (where there is abundance thereof) they never uſe any fire or water about it; only they corne it well with ſalt, and then preſſe out the oile, which is very fulſome and naught to be eaten, good only for lamps.

The oile of Almonds, which ſome call Metopium, is made of the bitter Almonds dried, ſtamped, and reduced into a maſſe or lumpe, which being ſprinkled and ſoked with water, and then beaten againe in a mortar, is put into a preſſe or mill, and the oile drawne thereout.

There is an oile made alſo of the Bay, togither with the oile of ripe olives readie to drop from the tree. Some take the Bay berries onely, & thereout preſſe oile de-Bayes: others uſe the leaves and nothing els: and there be againe, who with the leaves take alſo the rind of the Bay berries; yea and put thereto Storax Calamita, and other ſweet odors. Now for this purpoſe, the Lawrell with broad leaves, growing wild, and bearing blacke berries, is the beſt.

Like unto this oile, is that which they make of the blacke Myrtle; and the broad leafed kind thereof is the better: the berries of it ought to lie infuſed firſt in hot water, and afterwards to be boiled. Some ſeeth the tendereſt leaves that it hath in Oile-olive, and then preſſe them forth. Others put the leaves firſt in the oile, and then let them ſtand confected in the ſunne, and there take their ripening.

After the ſame manner is the oile made of the garden Myrtle; but that of the wild which hath the ſmaller ſeed is the better: and this Myrtle ſome call Oxymyrſine, others Chamæmyrſine; and ſome againe name it for the ſmalneſſe, * Acaron, for ſhort it is and full of little braunches.

* *i.* Indiviſible, or, ſo ſmal that it cannot be cut.

Moreover, there be oiles made of the Citron and Cypreſſe trees: likewiſe of wallnuts which they call Caryinon: alſo of the fruit of the Cedar, named Cedrelæon.

Semblably of the graine called Gnidium, to wit, the ſeed of Chamelæa and Thymelæa, well cleanſed and ſtamped. In like manner of the Lentiske. As for the oile Cyprinum, how it ſhould be made of the Ægyptian nut and of Ben for to ſerve perfumers, hath been ſhewed before. The Indians (by report) doe make of Cheſtnuts, of Seſame ſeed, & Rice. The people Ichthyophagi as they live by eating fiſh only, ſo they make oile of fiſhes. And in caſe of neceſſitie, otherwhiles men uſe to draw an oile out of the berries of a Plane tree alſo, beeing ſteeped in water and ſalt, which ſerveth for lamp oile. Yea and there is an oile made of the wild vine Oenanthe, as we have ſaid alreadie in the treatiſe of Ointments.

As touching the oile which the Greekes call Gleucinum, it is made with new wine and oile-olive, boiled at a ſoft fire. Others there be that let the wine conſume all into oile, and without any fire at all, doe compaſſe the veſſell wherein this compoſition is made, with the cake and the refuſe of grapes when they be preſſed, and cover it all over for the ſpace of 22 dayes, ſo as twice a day they be all mixed throughly togither. Some there be who put thereto not only Majoram, but alſo the moſt precious and exquiſite odours that they can meet withall: and our common fencing-halls and places of publicke exerciſes be perfumed with theſe ſweet oiles, and doe ſmell of them; but ſuch they be as are the cheapeſt of all other.

Over and beſides, there is made an oile of Aſpalathus, ſweet Calamus, Baulme, Iris or flour-de-lis, Cardumome or graines of Paradiſe, Melilot, French Nard, Panace, Marjoram, Elecampane, and the root of Cinamon, taking all theſe and letting them lie infuſed in oile, and ſo preſſing out the juice thereof. So is oile Roſat made of Roſes: the oile of Squinanth of the ſweet ruſh, which is moſt like to the oile Roſat. Likewiſe of Henbane, Lupines, and the Daffadill. The Ægyptians get great ſtore of oile out of Radiſh ſeed, or the graſſe called Gramen (which is Dent-de-chien or Quich-graſſe) and this oile they call Chortinon. After the ſame manner the Seſame-ſeed doth yeeld an oile; as alſo the Nettle, which in Greeke they call Cnecinon, or rather Cnidinum. As for the oile of Lilies, it is made in ſome places, where they feare not to let it ſtand abroad in the aire infuſed to take both ſunne and moon-ſhine, yea and froſtie weather.

They that inhabit between Cappadocia and Galatia, do compound a certaine oile of hearbs growing among them, which is a ſoveraigne remedie for ſinewes either wounded or otherwiſe grieved, and they call it Selgiticum: it is much in effect like to that oile which is made in Italie of Gums, by the people Eguini.

Now for the oile of Pitch, which they call Picinum, it is made of the vapours and ſmoke that ariſe from Pitch whiles it boileth, and received in fleeces of wooll ſpread over the pots mouth wherein

A wherein the ſaid Pitch is ſodden: which fleeces are afterwards well wrung, and the oile is preſſed out therof. The beſt oile is that which commeth from the Brutian or Calabrian Pitch: the ſame is moſt fat of all others, and fulleſt of Roſin. The colour of the oile is reddiſh.

Vpon the coaſts and maritime parts of Syria, there is an oile engendreth of it ſelfe, which the Greekes call Elæomeli: a fattie and greaſie ſubſtance it is, thicker than honey, and thinner than Roſin, of a ſweet taſt, iſſuing out of trees; and is onely medicinable and good in Phyſicke.

As touching old oile, it ſerveth in right good ſtead for ſundrie ſorts of maladies. It is thought alſo very ſingular for to preſerve Ivorie from putrefaction: for this is certein, that the image of *Saturne* at Rome is full of oile-olive all within.

B

Chap. viii.

Of the lees or dregs of Oile-olive, called Amurca.

C *Ato* hath highly commended above all, the lees of Oile-olive: for he would have the barrels, hogſheads, and other veſſels which hold oile, to bee therewith beſmeared, that they ſhould not drink up the oile. He deviſed alſo, that the threſhing floors ſhould be wrought and tempered with oile lees, that they might not chawn and gape, nor no Ants breed within the chinkes and cranies thereof. Moreover, he thinketh it very good that the mortar, plaſtre, and parget uſed about the walls of corne-barnes, as alſo their floores, ſhould be well ſprinckled and tempered with the ſaid lees: yea and the preſſes and wardrobes where apparell is kept, ought to
C be rubbed therewith to keepe out mothes, wormes, ſpiders, and ſuch vermine that doe hurt to clothes. He affirmeth beſides, that it is good againſt certaine diſeaſes of foure-footed beaſts, as alſo to preſerve trees, yea and excellent for inward ulcers of a mans bodie, but eſpecially thoſe of the mouth. Being ſodden, it is ſingular good (as he ſaith) for to annoint and make gentle and ſupple all bridle reines, leather thongs, ſhoes, and axeltrees of carts and wagons: likewiſe to keepe all veſſels of braſſe from ruſt, and alſo to give them a bright and pleaſant colour: moreover, all the wooden implements of an houſe generally throughout, and veſſels made of earth and clay, wherein one would keepe drie figges in their verdure, would bee annointed therewith:
D or if one were deſirous to preſerve the Myrtle, leaves, fruit, and all, upon the braunches, or any ſuch thing, there is nothing better than the ſaid Amurca. Laſt of all, he ſaith, that what wood ſoever for fewell is dipped in theſe lees, it will burne cleare without any ſmoke.

M. Varro affirmeth, that if a Goat chaunce to licke with his tongue, or to brouſe an Olive when it buddeth the firſt ſpring, the ſame tree will ſurely be barrain and lie in great daunger to miſcarrie and die. Thus much of the Olive tree, and of the oile of Olives.

Chap. ix.

All kinds of Fruit good to eat, and their nature.

AS for all other fruits of trees, they are hardly to be numbred and reckoned by their forme and figure; much leſſe by their ſundrie taſts and divers juices that they yeeld, ſo intermin-
E gled they are togither by varietie of graffing one into another.

Chap. x.

Of Pine-nuts or Pine-apples, foure ſorts.

THe Pine-nuts (which are the biggeſt of that kind and hanging higheſt upon the tree) doe contain and nouriſh ſlender kernels encloſed within certain hollow beds full of holes, and beſides clothed and clad with another coat or huske of a dark murrey colour: wherein may be ſeene the wonderfull care and providence of Nature, to beſtow the ſeeds ſo ſoft. A ſecond kind there be of theſe nuts called Terentines, having a ſhell or huske very brittle and eaſie to be
F cruſhed betweene ones fingers; and as ſoone are they pecked through with birds bills, who after that manner filch and ſteale them from off the tree. A third ſort yet there is of them, which come of the gentle Pitch trees, having their kernels couched within a thin huske or skin more like than a ſhell, and the ſame ſo ſoft, that it may bee chewed and eaten togither with the kernell. Now there is a fourth fruit growing of the wild Pine, and called thoſe Nuts are of the Grecians, Pity-

dia; and theſe be ſingular good againſt the cough. The Taurines in Calabria, have a device to confect Pine-nut kernels, by ſeething them in honey; and being thus condite, they call them Aquiceli. To conclude, at the ſolemne and feſtivall games holden at Iſthmus, they who win the beſt prize, are woont to be crowned with a chaplet of the Pine.

Chap. xi.

☞ *Of the Quince.*

NExt to Pine apples, for big and large, are the Quinces, which we call Cotonea, the Greeks Cydonea, becauſe they were firſt brought out of Candie. So heavie and maſſie they be, that they bend the boughs to the ground as they hang upon the tree, and will not ſuffer their mother to grow.

Many kinds there be of Quinces, to wit, Chryſomela, of a colour inclining to gold, & divided by certain cut lines. Secondly, there be the Quinces of our owne country, and ſo called: theſe be whiter, & of an excellent ſmell. They alſo that come out of the realm of Naples, be highly eſteemed. Now there be a ſmaller ſort of the ſame kind called Struthea [*i.* the Peare-quince] & thoſe doe caſt a more odoriferous ſmell: late they be ere they come to ripeneſſe or perfection; whereas contrariwiſe the greene Quinces called Muſtea, be as haſtie and ſoone melow. Now if a man doe graffe the great Quinces upon the Struthea, the tree will bring foorth a kind of Quinces by themſelves called Mulviana; and theſe are the Quinces alone of all other that may be eaten raw. In ſumme, all the ſort of theſe are come now adaies to be entertained within the waiting or preſence chambers of our great perſonages, where men give attendance to ſalute them as they come forth every morning; and in bed-chambeis alſo they are to garniſh the images ſtanding about the beds head and ſides.

There are beſides ſmall wild Quinces, next to the Peare-quince Struthea, for pleaſant and odoriferous ſmell; and they grow commonly in hedge-rowes.

Moreover, as well Peaches as Pomegranats, notwithſtanding they be of a divers kind, yet we call Mala [*i.* Apples.] As for the Pomegranats, we have ſpoken of nine ſorts of them in our treatiſe of their trees, and others in Affricke: and theſe are full of certaine graines or kernels lying encloſed under their rind; whereas Peaches have in ſtead thereof, a groſſe ſtone or woodie ſubſtance within the carnous pulpe of the fruit. To conclude, there be certaine Peares weighing a pound, in regard of which poiſe and bigneſſe that they beare, called they are Libralia.

Chap. xii.

☞ *Of the Peach, and foure kinds thereof.*

OF all Peaches, the principall be thoſe which are named Duracina, for the ſolide ſubſtance of the meat within them. As for the French and Aſiaticke Peaches, they beare the name of the regions and nations from whence they come. This fruit ordinarily waxeth ripe after the fall of the leafe, or Autumne: but the Abricocts are readie to be eaten in Summer. Theſe have not been knowne full thirtie yeares, and at their firſt comming up, were ſold for Romane deniers apeece: whereof there be two ſorts; Supernatia, which we have from the high countries, and namely the Sabines; and Popularia, which grow common every where. Theſe fruits bee harmleſſe, and much deſired of ſicke folke: and for that they are in ſuch requeſt, there would be given otherwhiles thirtie Seſterces for one of them; which is a price as high as of any other fruit whatſoever: whereat we may marvell the rather, for that there is not any ſooner gone, and laſteth leſſe while than they: for being once gathered from the tree, they will not be kept above two daies at the moſt, and therefore muſt of neceſſitie be ſold and ſpent out of hand.

Chap. xiii.

☞ *Of the Plum-tree, eleven kinds of them.*

TO come now to Plums, there is a world of them: ſome of ſundrie colours, others blacke, and ſome againe white. There be that are called Hordearia, becauſe they be ripe in barley-harveſt: and ſome there be of the ſame colour, yet later ere they ripen, and bigger beſides; and

A and for that they be of ſmall reckoning, named they are Aſinina [*i.* *Aſſe-plums.] Ye ſhall have of them that be black, howbeit the yellow wheat-plum like virgin wax, and the purple, are better eſteemed. Moreover, there are a kind of Abricots come from a forraine nation, and they be called thereupon Armeniaca, which alone for their ſmell alſo, are commendable. But there is a peculiar braverie and a ſhameleſſe, which thoſe Plums have by themſelves that are graffed in Nut-tree ſtocks; they retaine the face and forme ſtill of the mother graffe, but they get the taſt of the ſtocke wherein they are ſet, as it were by way of adoption: of them both they carrie the name, and are called Nut-plums. Now, as well theſe, as Peaches, yellow wheat-plums, and the wild Bullaiſe, may be kept and preſerved as grapes in Autumne, within certaine barrels or earthen veſſels, and ſo they will continue good till new come. As for all other Plums, as they be ſoon ripe; B ſo they are as ſoone gone.

* As our hoſt plums.

It is not long ſince, that in the realme of Granado and Andaluſia, they began to graffe plums upon apple-tree ſtocks, and thoſe brought forth Plums named Apple-plums: as alſo others called Almond-plums, graffed upon Almond ſtocks; theſe have within their ſtone a kernell like an Almond: and verily there is not a fruit againe wherein is ſeene a wittier deviſe to conjoyne and repreſent in one and the ſame ſubject, two divers ſorts.

As for Damaſcene-plums (taking name of Damaſco in Syria) wee have ſufficiently ſpoken thereof in our treatiſe of ſtraunge trees: and yet long ſince they have been knowne to grow in Italy: which although they have a large ſtone and little carnoſitie about them, yet they never wither into wrinkles and rivels when they be drie, for that they want the full ſtrength of the kind C ſunne which they had in Syria.

We ſhould do well to write togither with them, of the fruit Sebeſten, which alſo come from the ſame Syria, albeit now of late they begin to grow at Rome, beeing graffed upon Sorvices. As touching Peaches in generall, the very name in Latine, whereby they are called Perſica, doth evidently ſhew that they were brought out of Perſis firſt; and that it is a fruit not ordinarie either in Greece or Natolia, but a meere ſtraunger there. Contrariwiſe wild plums (as it is well known) grow every where. I marvell therefore ſo much the more, that *Cato* made no mention thereof, conſidering that of purpoſe he ſhewed the manner, how to preſerve and keepe divers wild fruits, untill new came: for long it was firſt ere Peach trees came into theſe parts, and much adoe there was before they could be brought for to proſper with us, ſeeing that in the Iland Rhodes (which D was their place of habitation next to Ægypt) they beare not at all, but are altogither barraine. And whereas it is ſaid, That Peaches be venimous in Perſia, and do cauſe great torments in them who doe eat therof; as alſo that the KK. of Perſia in old time cauſed them to be tranſported over into Ægypt by way of revenge to plague that country; and notwithſtanding their poiſonous nature, yet through the goodnes of that ſoile they became good and holeſome: all this is nothing but a meere fable and a lowd lie. True it is indeed, that the beſt writers who have been painfull above others to ſearch out the truth, have reported ſo much concerning the tree Perſea; which is far different from the Peach tree Perſica, & beareth fruit like unto Sebeſten, of colour red, and willingly would not grow in any countrey without the Eaſt parts. And yet the wiſer and more learned Clarkes do hold, That it was not the tree Perſea which was brought out of Perſis into Æ-E gypt, for to annoy and plague the countrey, but that it was planted firſt by king *Perſeus* at Memphis. Whereupon it came, that *Alexander* the Great ordained, That all victors who had woon the prize at any game there, ſhould be crowned with a chaplet of that tree, to honour the memoriall of his great grandſires father. But how ever it be, certain it is that this tree continueth green all the yeare long, and beareth evermore fruit one under another, new and old togither. And to returne againe to our Plum-trees, evident it is that in *Catoes* time they were not knowne in Italie, but all the Plum-trees which we now have, are come ſince he died.

Chap. xiiii.

Of nine and twentie kinds of Fruits, contained under the names of Apples.

F

OF Apples (that is to ſay, of fruits that have tender skins to be pared off) there be many ſorts. For as touching Pome-citrons, together with their tree, we have alreadie written. The Greekes call them Medica, according to the name of the countrey from whence they firſt came in old time. As for Injubes, as alſo the fruit Tuberes, they be likewiſe ſtraungers as

well as the reſt: and long it is not ſince they arrived firſt in Italie; the one ſort out of Affricke, the other (namely Injubes) out of Syria. And *Sextus Papinius* (whome my ſelfe in my time ſaw Conſull of Rome) was the firſt man that brought them both into theſe parts; namely, in the latter end of *Auguſtus Cæſar* the Emperour, and planted them about the rampiers of his camp for to beautifie the ſame: howbeit (to ſay a truth) their fruit reſembled rather berries than apples; yet they make a goodly ſhew upon the rampiers: and no marveile, ſince that now adaies whole groves of trees begin to over-top and ſurmount the houſes of privat perſons.

Concerning the fruit Tuberes, there be two ſorts thereof, to wit, the white, and the reddiſh, called alſo Sericum, of the colour of ſilke.

The apples named Lanata, are held in manner for ſtrangers in Italie, and are known to grow but in one place thereof, and namely within the territorie of Verona. Covered they be all over with a kind of down or fine cotton, which albeit both Quince and Peach be clad and overgrown with in great plentie, yet theſe alone carie the name thereof: for otherwiſe no ſpeciall propertie are they knowne by, to commend them.

A number of apples there are beſides that have immortalized their firſt founders and inventors, who brought them into name, & cauſed them to be known abroad in the world; as if therin they had performed ſome worthy deed beneficiall unto all mankind. In which regard, why ſhould I thinke much to rehearſe and reckon them up particularly by name? for if I be not much deceived, thereby will appeare the ſingular wit that ſome men emploied in graffing trees; and how there is not ſo ſmall a matter, ſo it be well & cunningly done, but it is able to get honor to the firſt author, yea and to eternize his name for ever. From hence it commeth, that our beſt apples take their denominations, of *Matius*, *Ceſtius*, *Manlius*, and *Claudius*. As for the Quince-apples (which come of a Quince graffed upon an apple ſtocke) they are called Appiana, of one *Appius* who was of the *Claudian* houſe, and firſt deviſed and practiſed that feat. Theſe apples carrie the ſmell with them of Quinces: they beare in quantitie the bigneſſe of the Claudian apples, and are of colour red. Now leaſt any man ſhould thinke, that this fruit came into credit by reaſon onely of partiall favour, for that the firſt inventor was a man deſcended from ſo auncient and noble a familie, let him but thinke of the apples Sceptiana, which are in as great requeſt as they, for their paſſing roundneſſe; and they beare the name of one *Sceptius* their firſt inventor, who was no better than the ſonne of a ſlave lately enfranchiſed. *Cato* maketh mention of apples called Quiriana, as alſo of Scantiana, which he ſaith the manner is to put up in veſſels, and ſo to keepe them. But of all others, the laſt that were adopted and tooke name of their patrons and inventors, be Petiſia: litle though they be, yet are they paſſing ſweet and pleaſant to be eaten.

Others apples there are that have ennobled the countries from whence they came, and caried their names, to wit, Camerina and Græcula. All the reſt tooke name, either upon ſome occaſion or propertie that they have: to wit, of brotherhood, as the twin-apples Gemella, which hang one to another by couples, and never are found ſingle, but alwaies grow double: of their colour, as the Serica, which for their freſh hew be ſo called: of kinred and affinitie, as the Melapia, for their reſemblance and participation of apples and Peares togither; as a man would ſay, Peare-apples, or Pom-poires: of their haſtie ripeneſſe, as the Muſtea, [*i.* haſtie-apples;] which now of their ſweet taſt of hony, are called Melimela, [*i.* hony-apples:] alſo of their exquiſite roundneſſe like a ball, as the Orbiculata, [*i.* the round-apples.] That theſe apples came firſt from their native countrey Epirus, appeareth by the Greeks who call them Epirotica. Againe, ſome there be that take their denomination of their forme, reſembling womens paps or breaſts, as namely, Orthomaſtica, [*i.* the Breſt-apples.] Others, for that their condition is to have no pepins or ſeed within them, be called of the Belgians, Spadoma, as one would ſay, Guelded-apples. As for the Melofolia, [*i.* the Leaſe-apples] they be ſo called, becauſe they have one leafe and otherwhile twaine breaking foorth of their ſide in the very mids. The ragged apples Pannucea take this name, for that of all others they ſooneſt be riveld. The Puffes named Pulmonea, are hoven fooliſhly, and ſwell I cannot tell how, with little or nothing in them. Some in colour reſemble bloud, they are ſo red, becauſe at firſt they were graffed upon a mulberry. But all apples ordinarily are red on that ſide that regardeth the ſunne.

As for Wildings and Crabs, little they be all the ſort of them, in compariſon: their taſt is well enough liked, and they carie with them a quicke and ſharp ſmell: howbeit this gift they have for their harſh fourneſſe, that they have many a foule word and ſhrewd curſe given them, and that they

A they are able to dull the edge of any knife that ſhall cut them. To conclude, the Dacian Apples are of all others in manner leaſt accepted, notwithſtanding they be firſt mellow, and would bee gathered betimes.

Chap. xv.

Of Peares. And of the varietie of graffing.

VPon the ſame cauſe there be Peares alſo reproched with the name of Pride, and are called the Proud-peares: little they are, but quickly ripe, and as ſoone gone. Of all others the Cruſtumine peares be moſt delicat and pleaſant in taſt. Next to them in requeſt are the Falerne peares, ſo called for their great abundance of liquor, as it were wine, whereof they are full. And theſe are named likewiſe the milke-peares: but ſuch of them as are of colour blacke, be called the Syrian peares. As for other peares, they have ſundrie names according to the countries wherein they grow. Howbeit theſe peares following, retaine their name ſtill in all places, and repreſent alwaies the memoriall of thoſe that firſt planted or graffed them, to wit, Decimiana of one *Decimus*, a knowne citizen of Rome: of which is alſo a baſtard kind which they call Pſeudodecimiana. Likewiſe, the Dolobellian peare, of one *Dolabella*: and thoſe are of all other the longeſt tailed. As touching the Pompeian peares, which be alſo called the Pap or Teat-peares, the Licerian, the Severian, and of their race the Tyrannian, they differ one from another in the length of their ſteale. The red Favonian peares be ſomewhat greater than the abovenamed Proud-peares. As for the Laterian and Anitian, which be not gathered nor ripe untill Autumne be paſt, they
C have a pretie tart and ſouriſh taſt, but natheleſſe pleaſant ynough. The Tyberian peares beare the name of *Tiberius* the Emperour, for that of all others he loved that fruit beſt: they might goe for Licerians well ynough, ſo like they be unto them, ſave onely that they grow big, and are more deepely coloured with the Sunne.

Moreover, there be peares which are known by no other name than of the countries where they grow, namely, thoſe of Ameria which are more lateward than any other: the Picentine, Numantine, Alexandrine, Numidian, Grecian, and among them the Tarentine. Alſo the Signine pears, which many call Teſtacea, of the colour of earthen pots which they reſemble; like as others be named Onychinum, for that they repreſent the Onyx ſtone, or a mans naile; as alſo thoſe which be called Purple-peares.

Furthermore, peares take their name of the odour which they yeeld: thus there be Myrapia, to wit, Aromaticall-peares, Laurell, and Nard-peares. Of the time alſo when they be ripe, as the Barley-peares: of the forme of their neck, as the Bottle-peares called Ampullacea: of their thick skin, as the Coriolana. As for the Gourd-peares, they are by nature of a bruiſh and ſavage kind; ſo harſh, ſo ſoure and eager a liquor they doe yeeld.

Many ſorts of peares there are, whereof we can give no certaine reaſon for their denomination, namely, the Barbarian and Venerian peares, which alſo be called Coloured: likewiſe, the roiall peares, which hang or rather ſticke flat to the tree, ſo ſhort a ſteele they have. The Patritian alſo and Voconian peares, which are both greene and long. Moreover, *Virgil* hath ſpoken of the Volemian peares or wardens, which he had from *Cato*, who alſo nameth the Sementium or the haſtie and ſoone ripe peares. So as in this point verily the world is growne alreadie to the higheſt pitch, inſomuch, as there is not a fruit, but men have made triall and many experiments, for even in *Virgils* daies the deviſe of graffing ſtrange fruits, was very riſe: conſidering that he ſpeaketh of the Arbute tree graffed upon Nut-trees, the Plane upon Apple trees, and the Elme upon Cherie ſtockes. In ſuch ſort, as I ſee not how men can deviſe to proceed farther. And certes for this long time, there hath not been a new kind of Apple or other fruit heard of.

And yet as induſtrious as men have been that way, they are not permitted to graffe all manner of trees indifferently one in another, no more than it is lawfull to graffe upon buſhes and thornes: ſeeing that it is not ſo eaſie a matter to appeaſe lightnings: for looke how many ſorts of trees are thus engraffed contrarie to nature, ſo many kinds of lightnings and thunderbolts by report, are flaſhed and ſhot at once.

Peares naturally are more ſharpe-pointed at one end than Apples. And among them, the Greeke peares, the Gourd and Lawrell peares are laſt of all others ripe: for they hang upon the tree untill Winter, and they mellow with very froſt: like as the Amerine and Scantiane apples.

Furthermore, peares are kept and preſerved as grapes, and after ſo many waies: but none of them

them are put in barrels as plums be. Finally, Peares and Apples both, have the properties of wine; and in like sort Physicians be warie how they give them to their patients. Howbeit, when they be sodden in wine and water, they serve in stead of a broth or grewell: and so doe no fruit else but Pome and Peare-Quinces.

Chap. XVI.

The manner how to preserve Apples.

THe generall rules to keepe and preserve Apples, are these. *Imprimis*, That the solars be well planked and boorded in a cold and drie place; provided alwaies, that the windowes to the North doe stand open, especially every faire day. *Item*, to keepe the windows into the South shut, against the winds out of that corner: and yet the North winds also where they blow, do cause Apples to shrinke and rivell ilfavouredly. *Item*, That Apples bee gathered after the Æquinox in the Autumne: and neither before the full of the Moone, nor the first houre of the day. Moreover, that all the Apples which fell, be severed from the other by themselves, and laid apart: also that they be bedded upon straw, mats, or chaffe under them: that they be so couched, as that they touch not one another, but have spaces betweene to receive equall aire for to be vented. To conclude, this is well knowne, that the Amerine Apples do last and keepe good long, wheras the honie Apples will abide no time.

Chap. XVII.

How to keepe Quinces, Pome-granates, Peares, Sorvises, and Grapes.

FOr the good keeping and preserving of Quinces, there must be no aire let into them where they are enclosed: or els they ought to be confected in sodden honey, or boiled therein.

Pomgranates should be plunged into sea-water boiling, and so hardened therein: and after that they be dried in the Sunne three daies, (so as they be not left abroad in the night to take dew) they would be hanged up in a solar, and when a man list to use them, then they must be well washed in fresh water. *M. Varro* setteth downe the manner to keepe them within great earthen vessels, in sand. And if they be not ripe, he would have the earthen pots bottomes broken off, and so the Pomgranates to be put in, and covered all over with mould: but the mouth thereof must be well stopped for letting any aire in; provided alwaies, that the steele and the braunch whereto the fruit groweth, be pitched. For so (quoth he) they will not give over to grow still, yea, & prove bigger than if they had remained upon the tree. As for other Pomgranates [*i.* that are ripe] they may be wrapped and lapped one by one in fig-leaves, such as are not fallen, but plucked from off the tree greene, and then to bee put into twigge paniers of oisiers, or els daubed over with potters clay.

He that would keepe Peares long, must put them in earthen vessels turned with the bottomes upward, well varnished or annealed within, covered also with saw dust or fine shavings, and so enterred. As for the Tarentine Peares, they abide longest on the tree ere they be gathered. The Anitian Peares be well preserved in cuit-wine.

As for Sorvisses, they are kept also in trenches within the ground, but the cover of the vessell whereinto they are put, ought to be well plastered all over, and so to stand two foot covered with earth: also they may be set in a place exposed open to the Sunne, with the bottome of the vessels upward: yea, and within great barrels they may be hung up with their braunches and all, after the manner of grape-clusters.

Some of our moderne writers handle this argument more deepely than others, and fetch the matter farre off, giving out rules in this manner, saying, That for to have Apples or Grapes *de garde*, that is to say, fit to be preserved, and to last long; the trees that beare the one and the other, ought to be pruned and cut betimes, in the waine of the Moone, in faire weather, and when the winds blow drie. Likewise they affirme, That fruits to be preserved, would be chosen from drie grounds: gathered before they be full ripe: and this would be looked unto in any hand, that the Moone at the gathering time, be under the earth, and not appearing in our hemisphære. And more particularly, for Grape bunches they would be gathered with a foot or heele from the old hard wood, and the Grapes that are corrupt and rotten among the rest, be clipped off with a

paire

paire of ſheeres,or plucked out with pincers: then to be hung up within a great new earthen veſſell well pitched; with the head or lid thereof throughly ſtopped and plaſtered up cloſe, to exclude all aire. After which manner, they ſay Sorviſſes and Peares may be kept, but ſo,as in any caſe the twigs and ſteeles whereby they hang, be well beſmeared with pitch. Moreover, order would be given,that the barrels or veſſels wherein they are kept,be far ynough from water.Some againe there be who keepe Grapes together with their braunch,after the ſame manner in plaſter: but ſo, as both ends of the ſaid braunch ſticke in the head of the ſea-Onion Squilla: and others let Grape-cluſters hang within hogſheads and pipes having wine in them: but ſo, as the Grapes touch not the wine in any caſe. There be alſo that put Apples and ſuch fruits in ſhallow pans or pancheons of earth,and let them ſwim and flote aloft upon the wine within their veſſels: for beſides that this is a way to preſerve them, the wine alſo (as they thinke) will thereby get a pleaſant and odoriferous taſt.Others yee have beſides,that chuſe rather to preſerve all theſe fruits, as well Apples,Peares, &c.as Grapes, covered in Millet ſeed. Howbeit, the moſt part dig a trench or ditch two foot deep in the ground,they floore it with ſand in the bottome,& lay their fruits therupon; then they ſtop the top with an earthen lid,and afterwards cover all with earth.Some there are which ſmeare their bunches of Grapes all over with potters clay,and when they are dried in the Sunne, hang them up in ſolars for their uſe: and againſt the time that they ſhould occupie them,ſteepe them in the water,and ſo waſh off the foreſaid clay. But for to keepe Apples that are of any worth,they temper the ſame clay with wine,and make a morter thereof,wherein they lap the ſaid Apples.Now if thoſe Apples be of the beſt kind and right ſoveraigne,after the ſame ſort they cover them with a cruſt of the like paſt or morter,or elſe clad them within a coat of waxe: and if they were not fully ripe before,they grow by that meanes, and breake their cruſt or cover what ever it be.But this would not be forgotten,that they uſe alwaies to ſet the Apple or fruit upright upon the taile,howſoever they be kept. Some there are who gather Apples and ſuch like fruit with their ſlips & ſprigs, hide them within the pith of an Elder tree,and then cover them in earth,as is before written.And others there are,who for every Peare or Apple,have a ſeverall earthen pot,and after that their lids be well cloſed and ſtopped with pitch,then they encloſe them againe with great veſſels or tuns.Nay, ye ſhall have ſome to lap them with flockes and wooll,and ſo put them in caſes,and them they ſee well luted with morter made of clay and chaffe tempered together. Some order them in the ſame ſort,but they put them in earthen pans:and others make no more adoe, but digan hole in the ground, floore the bottome with a courſe of ſand,put the Apples or fruit within,and then anone when they are thus buried,cover all with mould. There be that uſe Quinces in this wiſe; they take them,annoint them with waxe comming out of Pontus,and ſuffer them afterwards to lie covered in honie.

Columella mine author reporteth,That fruits will keepe well in earthen pots throughly pitched,and afterwards ſet in pits,and drenched in ceſternes of water. In the maritime coaſts of Liguria next to the Alpes, they uſe to take Grapes after they are dried in the Sun, and wrap them within bands of ruſhes and reeds,put them up in little barrels,and ſtop them cloſe with plaſter. The Greekes have the ſame faſhion: but they take for that purpoſe, the leaves of the Plane-tree,of the vine it ſelfe,or elſe the fig-tree,after they be dried one day in the ſhade: and when they be in the barrell,betweene every bed of grape cluſters, they couch a courſe of grape kernels, and ſuch refuſe remaining after the preſſe. And in this manner are the grapes of Coos and Berytus preſerved: and for ſweetneſſe and pleaſant taſt,there are no better to be found. And ſome there be, that for to counterfeit theſe excellent Grapes, beſmeare them with lie aſhes ſo ſoone as ever they be pulled from the Vine, and preſently drie them in the Sunne: which done, they enwrap them within leaves,as hath been ſaid before,and ſo couch them cloſe within the cake of preſſed grapes. Nevertheleſſe, there be divers that chuſe rather to keepe Grapes in the ſaw duſt or ſhavings of Firre wood, Poplar, or Aſh. Some are afraid to let Grapes hang neare to Apples, Pomegranates, and ſuch like fruit, and therefore give in charge to let them preſently after they bee gathered,for to bee hung up in garners or bourded lofts: ſuppoſing that the duſt which they gather from above, is the beſt cover to defend and preſerve them. The remedie to keepe Weſpes from them,is to ſpurt or ſquirt oile out of a mans mouth upon them. And thus much concerning the way to preſerve Grapes and other fruits aforeſaid. As for Dates, we have ſpoken ſufficiently before,of them.

CHAP.

Chap. xviii.

Of Figs, 29 ſorts of them.

OF all other fruits which have tender pils or skins, and are called in Latine, Poma, Figs are the biggeſt: for ſome of them are found to be as great as Peares. As touching the Sycomores of Ægypt and Cypres, and of their admirable fruit, we have written ynough in the treatiſe of forraine Trees. The Idæan Figs that come from the mountaine Ida, are of colour red, of the bigneſſe of Olives, onely rounder they be, & in taſt reſemble Medlars. In the region about Troas neare unto the ſaid hill Ida, they call that fig-tree Alexandrina. It is as thicke as a mans arme about at the cubite or elbow, and full of braunches: the wood thereof is tough and ſtrong, howbeit, pliable to wind and bend which way a man would have it. Void of milkie ſubſtance it is, clad with a greene barke, bearing leaves like the Tillet or Linden tree, but that they be ſoft. *Oneſicritus* writeth, that the Fig-trees in Hyrcania beare more pleaſant fruit than ours in Italie, without all compariſon: alſo that they carie a greater burden, and be farre more plentifull, inſomuch, as one of them doth ordinarily yeeld 270 Modij of Figs. We have here alſo in Italie many Fig-trees brought out of other forraine countries, to wit, from Chalcis and Chios: whereof there be many ſorts. For both our Lydian Figs which are of a reddiſh purple colour, and alſo the Mamillane or teat-Figs, have a reſemblance of the ſaid Chalcidian and Chian Figs, yea, and the Calliſtruthion Figs beyond others not a little, in goodneſſe of taſt: and theſe of all the reſt are the coldeſt. For as touching the Affricane Figs, which many men prefer before all others, they hold the name of Affricke, as if it were their native countrey: and yet there is a great queſtion thereabout, and I wot not well what to ſay thereof, conſidering that it is not long agoe that Affricke begun firſt to have Fig-trees. For the Alexandrine Figs are of the blacke kind, having a white rift or chamfre, and are ſurnamed Delicate. The Rhodian Fig is likewiſe blacke of hue: and ſo is the Tiburtine, which alſo is of the haſtie kind, and ripe before others.

Moreover, there be certaine Figges which beare the names of thoſe that brought them firſt into Italie: namely, the Livian and Pompeian, and ſuch are fitteſt to bee dried in the Sunne, and ſo to be kept all the yeare long for a mans uſe: like as the illfavoured, fooliſh, and gaping Figges Mariſcæ: as alſo thoſe that are ſpeckled with ſpots like the leaves of the Laconian reeds.

There are beſides the Herculanean, Albicerate, and Aratian white Figs, which of all other are moſt flat and broadeſt, and withall have the leaſt taile or ſteele whereby they hang. The Porphyrite Figs firſt ſhew upon the tree, and ordinarily are longeſt tailed. The ſmalleſt Figs called the popular Figs, which alſo are of all others the baſeſt and of leaſt account, come next after and beare the Porphyrites companie. Contrariwiſe, the Chelidonian Figges be the laſt: and ripen againſt Winter.

Moreover, certaine Figs there be which are both early, and alſo lateward: namely, ſuch as bear twice a yeare: and be both blacke and white: for they are ripe firſt in harveſt, and afterwards, in time of vintage. Late alſo it is before the Duracinæ be ripe, ſo called of the hard skin which they have. Alſo ſome there be of the Chalcidian kind which beare thrice a yeare. At Tarentum there grow none but ſuch as are exceeding ſweet, and thoſe they call Omas [or rather Oenadas, taſting of wine.]

Cato in his treatiſe of Figs writeth thus, The unſavorie Fig dotes, Mariſcæ, would be ſowne in an open, light, and chalkie ground. But the Affricane, Herculane, and the Winter Saguntine Figges, as alſo the Telliane (which are blacke and long tailed) love a fatter ſoile, or elſe well dunged.

After this, Figges have chaunged into ſo many kinds, and altered their names very often: in ſuch ſort, that by this point it is evident, how the world is altered, and to what varietie this life is ſubject. In ſome provinces, as namely in Mœſia, there be winter Figs that hang all Winter long: but they come to be ſuch, more by art and cunning, than naturally of themſelves. For ſo ſoone as Autumne is paſſed, and Winter approcheth, they uſe to cover with dung certaine little Fig-trees which they have, and together with them the greene yong Figs which they find upon them in Winter: and when they have continued ſo the ſharpe time of dead Winter, ſo ſoone as the weather beginneth to be more warme and temperate, they diſcharge both fruit and tree of their dung: which being thus let out againe (as it were) where they ſeemed buried, and now comming

A to light; they no ſooner find the freſh aire, and another kind of nouriſhment differing from that, whereby they lived, but doe embrace and receive the comfort of the new Sunne moſt greedily, as if they were new born and revived: in ſuch ſort, as that in Mœſia, notwithſtanding it be a moſt cold region, ye ſhall have the figs of theſe trees to ripen, when others begin to bloſſome: and by this meanes become early and haſtie figs in another yeare.

Now for as much as we are fallen to mention the figs in Affricke, which were in ſo great requeſt in the time of *Cato*, I am put in mind to ſpeake ſomewhat of that notable opportunitie and occaſion, which by the meanes of that fruit he tooke for to root out the Carthaginians, and raſe their very citie. For as he was a man who hated deadly that citie, & was otherwiſe carefull to provide for the quiet and ſecuritie of his poſteritie, he gave not over at every ſitting of the Senate, to
B importune the Senators of Rome, and to crie out in their eares, That they would reſolve and take order to deſtroy Carthage. And in very truth, one day above the reſt, he brought with him into the Senate houſe an early or haſtie fig which came out of that countrey: and ſhewing it before all the lords of the Senate, I would demaund of you (quoth he) how long agoe it is (as you think) ſince this figge was gathered from the tree? And when none of them could denie but that it was freſh and new gotten. Lo (quoth he) my maiſters all, this I doe you to weet, It is not yet full three daies paſt, ſince this figge was gathered at Carthage: ſee how neare to the wals of our cittie wee have a mortall enemie. Vpon which remonſtrance of his, preſently they concluded to begin the
C third and laſt Punicke warre, wherein Carthage was utterly ſubverted and overthrowne. Howbeit *Cato* ſurvived not the raſing and ſaccage of Carthage, for he died the yeare immediatly following this reſolution. But what ſhall we ſay of this man? whether was more admirable in this act, his provident care and promptneſſe of ſpirit; or the occaſion preſented by the ſuddaine object of the fig? was the preſent reſolution and forward expedition of the Senate, or the vehement earneſtneſſe of *Cato*, more effectuall to this enterpriſe? Certes, ſomewhat there is above all, and nothing in mine opinion more wonderfull, that ſo great a ſignorie and ſtate as Carthage, which had contended for the Empire of the world for the ſpace of a hundred and twentie years, & that, with the great conquerors the Romanes, ſhould thus be ruined and brought to nought, by occaſion of one fig. A deſſeigne, that neither the fields loſt at Trebia and Thraſymenus, nor the diſgrace received at the battell of Canna, wherein ſo many brave Romanes loſt their lives and left their dead bodies on the grounde to be enterred, could never effect: nay not the diſdain that they tooke to ſee the Carthaginians encamped and fortified within three miles of Rome, ne yet the bravadoes of *Annibal* in perſon riding before the gate Collina, even to dare them, could ever bring to paſſe. See how *Cato* by the meanes of one poore fig, prevailed to bring and preſent the forces of Rome to the very wals of Carthage.

There is a fig-tree called Navia, honoured with great reverence, in the common Forum and publicke place of juſtice at Rome, even where the ſolemne aſſemblies are held for elections of magiſtrates neare to the Curia, under the old ſhops called Veteres: as if the gods had conſecrated it for that purpoſe: neare (I ſay) it is to the Tribunall named Puteoli Libonis, & planted there by *Actius Navius* the Augur, where the ſacred reliques of his miracle, to wit, the Raſour and the Whetſtone, were ſolemnely enterred: as if it came of the owne accord from the ſaid Curia into the Comitium, and had not been ſet by *Navius*. This tree if it begin at any time to wither, there is another replanted by the Prieſts, who that way are very carefull & ceremonious. But a greater reſpect there is had of another in remembrance of the firſt fig-tree named Ruminalis (as it were) the nource of *Romulus* & *Remus*, the two young princes fondlings, and founders alſo of the citie of Rome: for that under it was found a ſhee Wolfe giving to thoſe little babes the teat (which in Latine they called Rumen:) and for a memoriall hereof there is a monument of Braſſe erected neare unto it, repreſenting that ſtraunge and wonderfull ſtorie. There grewalſo a third fig-tree before the temple of *Saturne*, which in the yeare 260 after the foundation of the citie of Rome, was taken away: at what time as a chappell was built there by the Veſtall nuns, and an expiatorie ſacrifice offered, for that it overthrew the image of *Sylvanus*. There is a tree of the ſame kind yet living, which came to grow of it ſelfe, no man knoweth how, in the middeſt of the Forum Romanum, and in that very place where was the deepe chinke and gaping of the ground, that menaced the ruine of the Romane Empire; which fatall and portentious gulfe, the renowned knight *Curtius* filled up with the beſt things that were to be found in the citie, to wit, his Vertue & Pietie incomparable, teſtified by a moſt brave and glorious death. In the very ſame place likewiſe there is

an

an Olive and a Vine,which came thither by as meere a chaunce,but afterwards well looked and trimmed by the whole people for to enjoy the pleasure of the shade therof. And there also stood an altar, which afterwards was taken away by occasion of the solemne shew of sword-fencers, which *Julius Cæsar* late Emperour,exhibited to doe the people pleasure,which were the last that plaied their prices and fought at the sharpe in the said Forum. To conclude,wonderfull it is to see, how the fruit of this tree maketh hast to ripe: a man would say that Nature therein sheweth all her skill and force to ripen figs all together at once.

Chap. xix.

Of the wild Fig-trees: and of caprification.

THere is a kind of wild fig-trees, which the Latines call Caprificus,that never bringeth any fruit to maturitie: but that which it selfe hath not, it procureth to others,and causeth them to ripen. For such is the interchangeable course & passage of causes in Nature,that as this thing putrifieth,that engendreth; and the corruption of one is the generation of another. By this it comes to passe, that the wild fig-tree breedeth certaine flies or gnats within the fruit thereof: which wanting nourishment, and not having to feed upon in those figs, because they become rotten and putrified as they hang upon the tree,they flie unto the other kind of gentle and tame fig-trees, where they settle upon the figs, and greedily nibble thereupon, untill they have made way,and pierced into them; and by that means let in at first the breath of the warme Sunne,and that comfortable and vegetative aire besides,that helpeth to ripen them. Soone after they sucke up and spend the milkie humor which they find there, and which keepeth the figs still as it were in their infancie,and hindereth their speedie and timely maturitie. True it is,that the figs in time would ripen of themselves by the power and benefite of Nature onely: howbeit, skilfull and industrious husbandmen take order alwaies to set these wild fig-trees near to the place where other fig-trees grow,but with due regard of the wind side,that when the foresaid gnats breake forth and are readie to flie out,a blast of wind might carie them to the other. And hereupon came the devise and invention to bring whole swarmes and casts of them as they hang one to another, from other places, that they might settle upon the figs to consume the raw moisture within. Now, if the soile be leane and hungrie,and the fig-trees growing thereupon exposed to the North wind, there is no such need of this help: for the figs will drie sufficiently of themselves,by reason as well of the situation of the place,as the clifts & rifts in them, which will effect that which the gnats or flies abovenamed might performe. The like effect is to be seene also where much dust is,namely, if a fig-tree grow neare unto an high way,much frequented and travelled by passengers. For the nature of dust is to drie and soke up the superfluous moisture of the milke within figges. And therefore when they are thus dried, whether it be by the meanes of dust,or of the said flies feeding, which is called Caprification, they fall not from the tree so easily: by reason they are discharged of that liquid substance,which maketh them both tender and also ponderous,weightie, and brittle withall.

All figges ordinarily are tender and soft in handling. Those which be ripe,have small graines within them: their succulent substance besides,when they begin to ripen,is white like milke: but when they are perfectly ripe,it is of the colour of honie. They will hang upon the tree untill they be old: and when they are aged, they yeeld a certaine liquor which distilleth from them in manner of a gum,and then in the end become drie.

The better sort of figges have this honour and priviledge,to be kept in boxes and cases for the purpose: and principally those that come from the Isle Ebusus, which of all others are the very best and largest: yea, and next to them those that grow in the Marrucines countrey. But where they are in more plentie,they put them up in great vessels called Orcæ,as namely in Asia: also in barrels and pipes,as at Ruspina,a citie in Barbarie. And in very truth,the people of those countries make that use of them when they be drie,that they serve both for bread and meat. For *Cato* setting downe an order for diet and victuals fit and sufficient for labourers, ordained, that they should be cut short of their other pittance,when figs are ripe,and make up their full meales with it. And it is not long since the manner came up, to eat fresh new figges with salt and poudered meats, in stead of cheese. And for to be eaten in this sort, the figges called Coctana, (wherof we have written before)and the dried figs Caricæ are commended: as also the Cauneæ,

which

A which when *M. Craſſus* ſhould embarke, in that expedition againſt the Parthians (wherein hee was ſlaine) preſaged ill fortune, and warned him not to go forward: namely, when at the very inſtant that he was readie to ſet foot a ſhipbourd, there was a fellow heard to crie thoſe figs for to be ſold, pronouncing alowd, Cauneas, Cauneas; which word in ſhort ſpeaking was all one with *Cave ne eas*, [*i.* Beware of this voiage, and goe it not.] All theſe ſorts of figs, *L. Vitellius* brought out of Syria, unto his ferme or manour that he had neare Alba, having been L. governour or Lieutenant generall in thoſe parts, namely, in the latter end of *Tyberius Cæſar* the Emperour: and the ſame *Vitellius* was afterward Cenſor at Rome.

Chap. xx.

B

Of Medlars: three kinds of them.

MEdlars and Serviſes, may well and truly be raunged in the ranke of Apples and Peares. Medlars be of three ſorts; namely, Anthedon, and Setania, and the third which they call Gallicum, [*i.* the French medlar] which is of a baſtard nature, yet it reſembleth the Anthedon, rather than the other. As for the Setanian medlar, the fruit is greater and whiter than the reſt; alſo the kernels or ſtones within are of a more ſoft ſubſtance, and not altogither ſo woodie and hard. The reſt are ſmaller than theſe Setania or common Medlars, but they have a better ſmell and more odoriferous, and withall will laſt longer. The tree it ſelfe that beareth Medlars, is reckoned among the greateſt ſort: the leaves before they fall, wax red: the roots be many
C in number, and run downe right deepe into the ground; by which means, unneth or very hardly, they be quite rooted up. This tree was not known in Italie by *Catoes* daies.

Chap. xxi.

Of Serviſes, foure kinds.

OF Serviſes there be foure ſundry ſorts, differing one from the other: for ſome of them are round like apples; others pointed at one end as Peares; a third kind are faſhioned like egs, as ſome long or tankard apples: and theſe are apt to be ſoone foure. For ſweet ſent and pleaſant taſt, the round excell all others: the reſt have a relliſh of wine. The beſt kind of
D them are they that have ſoft and tender leaves about their ſteles whereby they hang. The fourth ſort they call Torminale, allowed onely for the remedie that they affourd to mitigate the torments and wringing of the cholique. This tree is never without fruit, howbeit the ſmalleſt of all the reſt, and differeth from the other, for it beareth leaves very like to the Plane. There are none of them that beare fruit before they be three yeares old. Laſtly, *Cato* would have Serviſes to be preſerved and condite in Cuit.

Chap. xxii.

Of the Walnut.

E THe next place to theſe for bigneſſe, the Walnuts do challenge, which they cannot claime for their credit and authoritie; & yet they are in ſome requeſt among other licentious and wanton Feſcennine ceremonies, at weddings: for leſſe they be than Pine-nuts, if a man conſider the groſſeneſſe of the bodie outwardly; but in proportion therto they have a much bigger kernell within. Moreover, Nature hath much graced and honoured theſe nuts with a peculiar gift that ſhe hath endued them with, namely, a double robe wherewith they are clad: the firſt, is a tender and ſoft huske; the next, a hard and woodie ſhell: which is the cauſe, that at marriages they ſerve for religious ceremonies, reſembling the manifold tunicles and membranes wherein the infant is lapped and enfolded within the wombe: and this reaſon ſoundeth more probable, than that they ſhould bee ſcattered, becauſe in their fall they rebound and make a ratling [to
F drowne (forſooth) all other noiſes from the bride-bed or chamber.] That theſe Nuts alſo were brought out of Perſis firſt by commaundement of the Kings, is evident by their Greeke names; for the beſt kind of them, they call Perſicon, and Baſilicon; as one would ſay, the Perſian and Roiall nut: and theſe indeed were the firſt names. Afterwards, the nut came to be named Caryon, (by all mens confeſſion) for the heavineſſe of head which it cauſeth, by reaſon of the

ſtrong ſmell. Their outward huske ſerveth to die wooll, and the little nuts when they come new forth, are good to give the haire of the head a reddiſh or yellow colour: the experiment thereof was firſt found, by ſtaining folkes hands as they handled them. The elder that nuts be and longer kept, the more oleous and fatter they are. The onely difference of the ſundrie kinds, conſiſteth in the ſhell, for that of ſome it is tender and brittle, in others hard; in one ſort it is thin, in another thicke: laſtly, ſome have ſmooth and plaine ſhels, others againe be as full of holes and cranies. C

Walnuts be the fruit alone that Nature hath encloſed with a cover parted in twaine, and ſo is joined and ſet togither; for the ſhell is divided and cleft juſt in the mids, and ech halfe reſembleth a little boat. The kernell within is diſtinguiſhed into foure parts, and betweene every one there runneth a membrane or skin of a woodie ſubſtance. As for other nuts, their meat is ſolide and compact, as we may ſee in Filberds and Hazels, which alſo are a kind of nut, and were called heretofore Abellinæ, of their native place, from whence came good ones at firſt. They came out of Pontus into Natolia and Greece, and therefore they bee called Ponticke nuts. Theſe Filberds likewiſe are covered with a ſoft bearded huske, and as well the ſhale as the kernell is round and ſolide, all of one entire peece. Theſe nuts alſo are parched for to be eaten: and within their belly they have in the mids a little chit or ſpurt, as if it were a navill. H

As for Almonds, they are of the nature of nuts, and are reckoned in a third ranke. An upper huske they have like as Walnuts, but it is thin: like as alſo a ſecond coverture of a ſhell. The kernell differeth ſomewhat; for broader it is and flatter, and their skin more hard, more ſharpe, and hoter in taſt than that of other nuts. Now whether the Almond tree were in Italie during the life of *Cato*, there is ſome doubt and queſtion made; becauſe he nameth the Greeke nuts, which ſome doe hold for a kind of Walnut. Mention maketh he beſides of the Hazle nuts or Filberds, I

* or *Calvæ*, *i.* Bald.

as well the * Galbæ, as the Preneſtine, commended by him above all others, which he ſaith, are put up in pots and kept freſh and greene within the earth. Now adaies the Thaſian and Albeuſian nuts be in great account: and two ſorts beſides of the Tarentine; whereof the one hath a tender and brittle ſhell, the other as hard: and thoſe are the biggeſt of all other, and nothing round. He ſpeaketh alſo of the ſoft-ſhaled Filberds Molluſcæ, the kernels whereof doe ſwell and cauſe their ſhells to cleave in ſunder.

But to returne againe to our Walnuts: ſome to honour them, interpret their names Iuglandes, as a man would ſay, the nuts of *Iupiter*. It is not long, ſince I heard a knight of Rome (a gentleman of high calling and who had been Conſull) profeſſe and ſay, That he had certaine Walnut trees that bare twice a yeare. As for Fiſticks, we have ſpoken alreadie of them. To conclude, K
theſe kind of nuts the above-named *Vitellius* brought firſt into Italy at the ſame time, namely, a little before the death of *Tyberius* the Emperour: and withall, *Flaccus Pompeius* a knight of Rome, who ſerved in the warres togither with him, carried them over into Spaine.

Chap. xxiii.

Of Cheſtnuts, eight kinds.

WEe entitule Cheſtens alſo by the name of Nuts, although indeed they are more aptly to be called a kind of Maſt. This fruit what ever it be, is encloſed within an huske, L
and the ſame defended and armed all over with a rampier and palaiſade (as it were) of ſharpe pricks like the skin of an Vrchin; whereas the Acorne and other maſt is but halfe covered, and that defence in them, is begun only. And certes, a wonderfull matter it is, that we ſet ſo little ſtore by this fruit, which Nature is ſo carefull to hide and defend. Vnder one of theſe husks ye ſhall find ſometime three Cheſtnuts, and thoſe having certain tough pills or ſhells very pliable. But the skin or filme within, and which is next to the bodie or ſubſtance of the fruit, unleſſe it bee pilled off and taken away, marreth the taſt of it, like as it doth alſo in other nut-kernels. Cheſtnuts, if they be roſted, are better and more pleaſant meat than otherwiſe. They uſe alſo to grind them to meale, and therof is made a kind of bread that poore women for hunger will eat. The firſt Cheſtnuts were knowne to grow about Sardis, and from thence were brought, & there- M
fore the Greekes call them Sardinian nuts: but afterwards they came to he named Διὸς Βαχανί, [*i. Iupiters* nuts] when as men began to graffe them; for thereby they became more excellent: and at this day there be many ſorts of them. The Tarentine be gentle, and not hard of digeſtion, and in forme flat and plaine. That which they call Balanitis, is rounder, it will ſoone be pilled and cleanſed,

cleanſed, and of it ſelfe will leape out of the skin. And of this kind, the Salarian is more neat, flat, and ſmooth: the Tarentine not ſo eaſie to bee handled and dealt withall: the Corellian is more commended than the reſt; as alſo the Meterane, which commeth of it by graffing: the manner whereof wee will ſhew when wee come to treat of graffes. Theſe have a red pilling, in which regard they are preferred before either the three cornered, or the blacke common ones, which be alſo called Coctivæ, [*i.* Cheſtnuts to be boiled.] The beſt Cheſtnuts are they which grow about Tarentum, and Naples in Campaine. All the reſt are good in manner for nothing but to feed ſwine: * ſo cloſe ſticketh the pill or inner skin alſo, as if it were ſoudered to the kernell within, and ſo hard is it to ſeparate the one from the other.

* *Scrupuloſa corticis interioris circa nucleos quoque ferrumination.*

Chap. XXIIII.

Of Carrobes: of fleſhie and pulpous fruits: of Mulberries: of liquid kernels or graines, and of berries.

THe fruit called Carobes or Caracts, may ſeeme to come neare unto the foreſaid Cheſtnuts, (ſo paſſing ſweet they be) but that their cods alſo are good to be eaten. They bee as long as a mans finger, and otherwhiles hooked like a faulcheon, and an inch in bredth. As for maſt, it cannot be reckoned among fruit properly called Poma, and therefore we will ſpeake of them apart, according to their nature.

Now are we to treat of the reſt which are of a carnous ſubſtance: and thoſe are divided into fruits that be ſoft and pulpous, and into berries. The carnoſitie in Grapes and Raiſons, in Mulberries, and the fruit of the Arbut tree, differeth one from the other. Again, the fleſhie ſubſtance in Grapes between the skin and the liquid juice, is one, and that in Sebeſten is another. Berries have a carnoſitie by themſelves, as namely Olives. Mulberries yeeld a juice or liquor within the pulpe thereof, reſembling wine. They be ordinarily of three colours: at the beginning, white; ſoone after, red; and when they be ripe, blacke. The Mulberrie tree bloometh with the laſt, but the fruit ripeneth with the firſt. Mulberries when they be full ripe, ſtaine a mans hands with the juice thereof, and make them blacke: but contrariwiſe being unripe, they ſcoure them cleane. There is not a tree againe, wherein the wit of man hath been ſo little inventive, either to deviſe names for them, or to graffe them, or otherwiſe, ſave only to make the fruit fair and great. There is a difference which we at Rome doe make, betweene the Mulberries of Oſtia and Tuſculum.

There is a kind of Mulberries growing upon the bramble, but their skin is much harder than the other. Like as the ground-ſtrawberries differ in carnoſitie from the fruit of the Arbut tree, and yet it is held for a kind of Strawberrie, even as the tree it ſelfe is tearmed the Strawberry tree. And there is not a fruit of any other tree, that reſembleth the fruit of an hearb growing by the ground, but it.

The Arbut tree it ſelfe ſpreadeth full of braunches: the fruit is a whole yeare in ripening: by which means a man ſhall find alwaies upon the tree, yong and old fruit togither one under another; & the new evermore thruſteth out the old. Whether it be the male or female that is barren, writers are not agreed. Surely the fruit is of baſe or no reckoning at all: no marveile therfore if the Latines gave it the name Vnedo, for that one of them is enough to be eaten at once. And yet the Greeks have two names for it, to wit, Comarum and Memecylon: whereby it appeareth, that there be as many kinds among the Latines alſo, although it be tearmed by another name, Arbutus. K. *Iuba* ſaith, that theſe trees in Arabia grow to the heigth of fiftie cubits.

As touching Graines and liquid Kernels, there is great difference between them: for firſt and foremoſt, among very grapes, there is no ſmall diverſitie in the skin, either for tendernes or thickneſſe: in the inner ſtones or pepins, which in ſome grapes are but ſingle, or one alone; in others double, and thoſe commonly yeeld not ſo much wine as the others doe. Secondly, thoſe of Ivie and Elder differ very much: yea and the graines within a Pomegranat are not like to others in their forme, for they alone be made cornered and angle-wiſe; and ſeverall as they be, they have not a particular skin of their owne, but they are altogither clad within one, which is white: and yet they ſtand all wholly of a liquor and pulpous carnoſitie, eſpecially thoſe which have within them but a ſmall ſtone or woodie kernell.

Semblably, there is as much varietie in berries: for Olives differ much from Bay berries: likewiſe thoſe of the Lote tree are divers from them which the Corneil tree beareth. The Myrtle alſo

differeth from the Lentiske in the very berrie. As for the hulver or holly berries, and the hawes of the white-thorne, they are without any juice or liquor: whereas Cherries bee of a middle kind, betweene berries and graines. This fruit is white at the first, as lightly all berries be whatsoever: but afterwards, some wax green, as Olives and Baies; others turn red, as Mulberries, Cherries, and Cornoiles; but in the end they all become blacke, as Mulberries, Cherries, and Olives.

Chap. xxv.

Of Cherries, eight kinds.

BEfore the time that *L. Lucullus* defeated K. *Mithridates*, there were no Cherrie-trees in Italie: but after that victorie (which was about the 680 yeare from the foundation of the city of Rome) he was the man that first brought them out of Pontus, and furnished Italie so well with them, that within six and twentie yeares, other lands had part thereof, even as far as Britaine beyond the ocean. Howbeit (as we have before said) they could never be brought to grow in Ægypt, for all the care and industrie employed about them. Of Cherries, the reddest sort be called Apronia; the blackest, Actia: the Cæcilian be round withall. The Iulian Cherries have a pleasant taste, but they must bee taken newfrom the tree and presently eaten; for so tender they be otherwise, that they will not abide the carriage. Of all other, the Duracine Cherries be the soveraign, which in Campaine are called Pliniana. But in Picardie, and those low countries of Belgica, they make most account of the Portugall Cherries: as they do likewise who inhabit upon the river Rhene. They have a hew with them composed of three colours, between red, black, and green, & alwaies looke as if they were in ripening still. It is not yet full five years since the Cherries which they call Laurea, were known: so called they be, because they were grafted upon a Baytree stocke, and thereof they take a kind of bitternesse, but yet not unpleasant to the taste. There be moreover Macedonian Cherries, growing upon a small tree seldom above three cubits high: and yet there be certain dwarfe Cherries not full so tall, called Chamæcerasti, [*i.* ground cherry-shrubs.] The Cherrie-tree is one of the first that yeeldeth fruit unto his master, in token of thankfulnesse & recognisance of his paines all the yeare long. It delighteth to grow in cold places and exposed to the North. The Cherrie will drie in the sunne, and may be kept in barrels like Olives.

Chap. xxvi.

Of the Corneile and Lentiske tree.

THe same care is had in conditing the berries of the Corneil and the Lentiske, as in preserving Olives: so curious are men to content their tooth, as if all things were made to serve the belly. Thus we see, how things of divers rellishes are mingled togither, and one giveth a taste unto another, and causeth it to be pleasant at the tongues end. Nay we entermingle all climats and coasts of heaven and earth to satisfie our appetite: for to one kind of meat wee must have drugs & spices fetcht as far as from India: to another, out of Ægypt, Candie, and Cyrene: and in one word, for every dish wee have a severall land to find us sawce. To conclude, wee are growne to this passe, that wee cease not to sophisticate our viands, even with hurtfull things, so they taste well: yea and to make dishes of very * poisons, because we would devoure and send all downe the throat. But more plainely hereof, in our professed discourse of the nature and vertue of Hearbs.

* Mushroms.

Chap. xxvii.

The diversitie of tasts and savors.

IN the mean time, as touching those things which are common as wel to all fruits, as juices and liquors: first and foremost we find of tasts thirteen severall kinds; to wit, sweet, pleasant, fattie, bitter, harsh and unpleasant, hot and burning at the tongues end, sharpe and biting, tart or astringent, sowre, and salt. Over and besides all these, there be three others of a most strange and wonderfull nature: The first is that, wherein a man may have a smacke of many tasts togither, as in wines: for in them a man shall find an harsh, sharpe, sweet, and pleasant rellish all at once; and yet these all differ from the native verdure of wine. A second sort there is besides, which carieth a straunge and different taste verily from the thing it selfe, and yet it hath besides the proper and peculiar

A culiar taſt of the owne ſubſtance, as the Myrtle: for it carrieth a ſeverall taſt by it ſelfe, proceeding from a certain kind, mild, and gentle nature, which cannot truly be called either ſweet, fattie, or pleaſant, if we would ſpeake preciſely. Laſt of all, water hath no taſt at all of any juice or liquor whatſoever, and yet therein is a flat taſt by it ſelfe, which is called wateriſh, that nothing els beſides hath: for if a man doe taſt in water a relliſh of any ſap or liquor, it is reputed for a bad and naughtie water.

Furthermore, a great and principall matter of all theſe taſts, lyeth in the ſavour and ſmell; which is connaturall unto the taſt, and hath a great affinitie with it: and yet in water, is neither one or other to be perceived: or if any be felt either by tongue or noſe, it is faultie, that is certain. Finally, a wonderfull thing it is to conſider, that the three principall Elements whereof the world
B is made, namely, Water, Aire, and Fire, ſhould have no taſt, no ſavour, nor participation of any ſap and liquor at all.

Chap. xxviii.

The iuyce and ſap of Fruits and Trees: their colours and odours: the nature of Apples, and ſuch ſoft Fruits: and the ſingular commendation of all Fruits.

TO begin withall, The Peare, the Mulberrie, and the Myrtle-berrie, have a juice or ſap within them, reſembling wine; * no marveile then, of Grapes, if they have the like. Olives, Bay-
C berries, Walnuts, and Almonds, have a fattie liquor in them. The Grape, the Fig, and the Date, carie a ſweet juice with them. Plums have a wateriſh taſt.

There is no ſmall difference in the colour alſo that the juice of fruits doe beare: Mulberries, Cherries, and Corneils, have a ſanguine and bloudie liquor: ſo have the blacke grapes; but that of the white grapes, is likewiſe white. The juice of Figs toward the head or necke of the fruit, is white like milke; but of another colour in all the bodie beſides. In Apples, it is in manner of a froth or fome: in Peaches, of no colour; and yet the Duracina of that kind, be full of liquor; but who was ever able to ſay, what colour it was of?

The odour and ſavour likewiſe of fruits, is as ſtraunge and admirable: for the ſmell of Apples is ſharpe and piercing; of Peaches, weake and wateriſh. As for ſweet fruits, they have none at all:
D for verily we ſee, that ſweet wines likewiſe have little or no ſmell, whereas the ſmall and thin are more odoriferous: and all things in like manner of a ſubtill ſubſtance, doe affect the noſthrils more, than the thicke and groſſer doe: for whatſoever is ſweet in ſent, is not by and by pleaſant and delicat in taſt; for ſent & ſmack are not alwaies of like ſort: which is the reaſon that Pome-citrons have a moſt piercing and quicke ſavor, whereas in relliſh they are rough and harſh: and ſo it fareth in ſome ſort with Quinces. As for Figs, they have not any odor. And thus much may ſuffice in generall, for the ſundry kinds and ſorts of fruits which are to be eaten: it remaineth now to ſearch more narrowly into their nature.

To begin then with thoſe that are encloſed within cods or husks: ye ſhall have ſome of theſe cods to be ſweet, and the fruit or ſeed contained within, bitter: and contrariwiſe, many of thoſe
E graines or ſeeds are pleaſant and toothſome enough; but eaten with the huskes, they bee ſtarke naught and loathſome.

As touching berries, there be that have their ſtone or woodie ſubſtance within, and the fleſhy pulpe without, as Olives, and Cherries: and there bee againe, that within the ſaid woodie ſtone have the carnoſitie of the berry, as ſome fruits in Ægypt, whereof wee have alreadie written. As for berries carnous withoutforth, and pulpous fruits called Apples, they be of one nature. Some have their meat within, & their woodie ſubſtance without, as nuts: others, their carnoſitie without, and their ſtone within, as Peaches and Plums. So that in them we may ſay, That the faultie ſuperfluitie is environed with the good fruit, whereas fruit otherwiſe is ordinarily defended by the ſaid imperfection of the ſhell. Walnuts and Filberds are encloſed with a ſhell: Cheſtnuts be
F contained under a tough rind, which muſt be pulled off before they be eaten; whereas in Medlars, the carnoſitie and it be eaten togither. Acornes, and all ſorts of maſt, be clad with a cruſt; Grapes with a skin, Pomegranats with a rind and a thin pannicle or skin beſides. Mulberries doe conſiſt of a fleſhie ſubſtance and a liquor. Cherries, of a skin & a liquid juice. Some fruits there be, the ſubſtance whereof will ſoon part from their woodie ſhell without, or ſtone within, as nuts

* *Minimè quod miremur uvis.* Others diſtinguiſh thus, *Minimè (quod miremur) uvis*, to this ſenſe: whereas in grapes (& that may be a wonder) there is none ſuch.

and Dates: others ſticke cloſe and faſt thereto, as Olives and Bay berries. And there be againe that participate the nature of both, as Peaches: for in thoſe that be called Duracina, the carnous ſubſtance cleaveth hard to the ſtone, ſo as it cannot be plucked from it; whereas in the reſt, it commeth eaſily away. Now ye ſhall meet with ſome fruits, that neither without in ſhell, nor within-forth in kernell, have any of this woodineſſe, as a kind of Dates [named Spadones.] And there be againe whoſe verie kernell and wood is taken for the fruit it ſelfe, and ſo uſed; as a kind of Almonds, which (as we ſaid) doe grow in Ægypt. Moreover, yee ſhall have a kind of fruits furniſhed with a double ſuperfluitie of excrement to cover them without-forth, as Cheſtnuts, Almonds, and Walnuts. Some fruits have a ſubſtance of a threefold nature, to wit, a bodie without; then, a ſtone or wood under it; and within the ſame, a kernell or ſeed, as Peaches. Some fruits grow thicke and cluſtred togither upon the tree, as Grapes, and likewiſe Serviſes, which claſpe about the braunches and boughes, bearing and weighing them downe as well as grapes. Others for it, hang here and there very thin, as Peaches. And there be againe that lye cloſe, contained (as it were) within a wombe or matrice, as the kernels of the Pomegranats. Some hang by ſmall ſteles or tailes, as Peares: others in bunches, as Grapes and Dates. Ye ſhall have ſome fruit grow by cluſtres, and yet hang by a long taile, as the berries of Ivie and Elder: and others againe cleave faſt to the braunch of the tree, as Bay berries: ſome both waies, as Olives; for there be of them that have long ſteles, and others again ſhort tailed. Some fruits there be alſo, that are formed like cups or mazers, as Pomegranats, Medlars, the Ægyptian Beane or Lote, and that which groweth about the river Euphrates.

As for the ſingularities and commendable parts in fruits, they be of divers ſorts. Dates are moſt ſet by for their fleſhie ſubſtance; and yet they of Thebes above in high Ægypt, are eſteemed onely for their outward coat or cruſt that they have. Grapes, and the Dates called Caryotæ, are in great account and eſtimation for their juice and liquor: Peares and Apples be moſt accepted for their callous ſubſtance next unto their skin or paring; but the honey-apples Melimela, are liked for their carnoſitie and fleſhie pulpe within: Mulberries content the taſt with their griſtle or cartilage ſubſtance: and the beſt part of the nut, is the verie graine of the kernell. In Ægypt, ſome fruits are regarded onely for their utmoſt skin, as drie Figs: when Figges bee greene, the ſame is pilled off and caſt aſide like a ſhell; but be they once drie, the ſaid skin is paſſing good. In all kind of Papyr-reeds, Ferula plants, and the white thiſtle Bedegnar, the verie maine ſtemme is the fruit for to be eaten. The ſhoots alſo and tender ſprigs of the Fig-tree, are reputed for good meat, and alſo medicinable. To come unto the ſhrubs kind, the fruit of Capres is eaten togither with the ſtalke. As for the Carobe, what is it elſe but a meere woodie ſubſtance that folke doe eat? (and yet the ſeed and graines within them, are not altogither to be deſpiſed for the propertie that they have) although to ſpeake preciſely, it cannot properly bee called either fleſh, wood, or griſtle; neither hath it found any other convenient name to bee tearmed by.

Chap. xxix.

Of the Myrtle, eleven kinds thereof.

NAture hath ſhewed her wonderfull power and bountie, eſpecially in the juice of the Myrtle, conſidering that of all fruits, it alone doth yeeld two ſorts both of oile and wine: likewiſe the mixture or compoſition called Myrtidanum, as we have ſaid before. Alſo there was another uſe in old time of Myrtle berries: for, before that Pepper was found and uſed as it is, they ſerved in ſtead thereof: from whence tooke name that exquiſite and daintie diſh of meat, which even at this daie is called Myrtatum. And hereof came that excellent ſauce ſo highly commended for the brawne of the wild Bore, when for the moſt part Myrtle berries are put thereto to dip the meat therein, for to give a better taſt to that kind of veniſon.

As for the very tree it ſelfe, the firſt that ever was ſeene within the compaſſe and precincts of Europe (which beginneth at the mountaines Ceraunia) was about Circeij, where ſtood the tombe ſomtimes of *Elpenor*; and ſtill it retaineth the Greeke name: whereby we may well judge, that it is a ſtraunger. Howbeit there grew a Myrtle tree in old time, when Rome was firſt founded, even in that plot of ground where the cittie now ſtandeth. For thus goeth the hiſtorie: That upon a time the Romanes and Sabines being raunged in battaile array, and at the point

to fight a field, and to trie the quarell (for the wrong which the Sabines pretended, was done unto them, in regard that the Romanes had raviſhed their daughters being young maidens) were reconciled and made friends: and thereupon laid downe their armes and weapons, and were there purified with the ſacred branches of Myrtle, in that very place wherein now the temple & image of *Venus Cluacina* ſtandeth: which thereupon tooke the name (for that *Cluere* in old Latine, ſignified to purge or cleanſe.) Beſides, that tree otherwiſe doth affourd a kind of ſweet perfume to bee burned. Now was this tree choſen for that purpoſe then to make attonement and to ratifie the mariage betweene the Romanes and the Sabine virgines, becauſe *Venus* is the preſident and mother of carnall copulation, and the patroneſſe withall of the Myrtle tree. I will not confidently avouch, but me thinks I may preſume to ſay, That the Myrtle was of all other trees firſt planted in the publicke places of Rome for ſome memorable preſage and fore-tokening of future events and things to come. For whereas the temple of *Quirinus* (that is to ſay, of king *Romulus*) is reputed for one of the moſt antique buildings now extant, there grew even before it for a long time two old and ſacred Myrtle trees: the one named Patritia [*i.* the Myrtle of the Nobilitie:] and the other Plebeia; that is to ſay, the Myrtle of the Comminaltie. The Patritian proſpered and flouriſhed many yeares together, whiles the Plebeian began to fade and wither. And to ſay a truth, ſo long as the Senate was able to maintaine and uphold their authoritie, the Myrtle of the Nobles continued freſh and greene, and ſpread her boughes at large; whereas that other of the Commons ſeemed as it had been blaſted, dried, and halfe dead: but after that the ſtate of the Senate began to quaile and droupe, (which was about the time of the warre with the Marſyans) as their tree decaied and waſted, ſo the Plebeians Myrtle held up the head againe: and ſo by little and little, as the majeſtie of the Senatours was taken downe and abated to nothing, ſo their Myrtle waxed poore and barren untill it became drie and ſtarke dead. Moreover, there ſtood an old chappell and an altar conſecrated unto *Venus Myrtea*, whom now at this day they call Murtia.

Cato in his time wrote of three kinds of Myrtle: to wit, the white, the blacke, and the Conjugula (ſo called haply of wedlock or mariage:) and peradventure it may come of the race of thoſe Myrtles belonging to *Venus Cloacina* abovenamed. Howbeit, in theſe daies we diſtinguiſh our Myrtles otherwiſe; for ſome we repute wild and ſavage, others tame and gentle: and theſe both are likewiſe of two ſorts, to wit, either broader or narrower leaved. To the wild kind properly belongeth the prickie Myrtle Oximyrſine. As for the tame and gentle Myrtles, they bee thoſe that are planted in hort-yards and gardens, wherewith gardeners make arbors, knots, and divers deviſes. Whereof be ſundrie kinds. The Tarentine with ſmall leaves; ours of Italie with broader; and the myrtle *Hexaſtica, which is very ful of leaves, and ordinarily each branch hath ſix ranks thereof. But theſe are altogether out of requeſt: both the other are full of boughes and branches. As touching the abovenamed Conjugula, I ſuppoſe it bee the ſame that our common Myrtle here in Italie. But the moſt odoriferous Myrtle of all others, is that which groweth in Ægypt.

* not Exotica, *Turneb.*

Now concerning the wine of Myrtles, *Cato* hath ſhewed us the manner how to make it: namely, to take the blacke Myrtle berries, to drie them in the ſhade untill they have loſt all their wateriſh humiditie, and ſo to put them in Muſt or new wine, and let them lie there infuſed, or in ſteep. For certainely, if the berries be not dried before, they would yeeld an oile from them. Howbeit, afterwards there was a deviſe found out to make a white wine of the white Myrtle in this manner. Take of Myrtles well beaten or ſtamped, the quantitie of two *Sextares, ſteepe the ſame in three hemires or pints of wine, and then ſtraine and preſſe forth the liquor.

* *i.* wine-quarts.

Moreover, the very leaves of the Myrtle tree, being dried and reduced into a kind of meale, are ſingular good for to cure the ulcers in mens bodies: for certaine it is, that this powder doth gently eat away and conſume the ſuperfluous humours that cauſe putrifaction. And beſides, it ſerveth well to coole and repreſſe immoderate ſweats. Over and beſides, the oile alſo of Myrtles (a ſtraunge and wonderfull thing to tell) hath a certaine rellice and taſt of wine: and withall, the fat liquor thereof is endued with a ſpeciall and principall vertue to correct and clarifie wines; if the bagges and ſtrainers where-through the wine runneth, bee firſt ſoaked and drenched therewith: for the ſaid oleous ſubſtance retaineth and keepeth with it all the lees and dregs, and ſuffereth nothing but the pure and cleare liquour to paſſe through, and more than that, it carrieth with it the commendable odor and principall vertue of the ſaid oile. Furthermore it is ſaid, That if a wayfaring man that hath a great journey for to goe on foot, carrie

in

in his hand a ſticke or rod of the Myrtle tree, he ſhall never bee wearie, nor thinke his way long and tedious. Alſo *rings made of Myrtle twigs, without any edged yron toole, keepe downe and cure the ſwelling bunch that riſeth in the groine. What ſhould I ſay more? The Myrtle intermedleth in warre affaires: For *Poſthumius Tubertus*, being Conſull of Rome (who was the firſt that entred in a pettie triumph, ovant into the cittie, becauſe he had eaſily conquered the Sabines, and drawne in manner no bloud of them) rode triumphant in this manner, to wit, crowned with a chaplet of Myrtle, dedicated to *Venus Victreſſe*: and from that time forward the Sabines (even his very enemies) ſet much ſtore by that tree, and held it in great reverence. And ever after, they that went but ovant into the cittie after a victorie, ware this kind of guirland onely, except *M. Craſſus*, who after hee had vanquiſhed the fugitive ſlaves, and defeated *Spartacus*, marched in a coronet of Lawrell. *Maſſurius* writeth, how Generals when they entred triumphant into Rome, riding in their ſtately chariots (which was the greateſt honor of all others) ware upon their heads, chaplets of Myrtle. *L. Piſo* reporteth, That *Papyrius Maſſo* (who firſt triumphed in mount Albanus over the Corſians) uſed ever after to come unto the Games Circenſes, and to behold them, crowned with a guirland of Myrtle. This *Papyrius* was grandfather by the mothers ſide, to the ſecond *Scipio Africanus*. Finally, *M. Valerius*, according to a vow that hee made in his triumphs, uſed to weare coronets as well of Lawrell as Myrtle.

*Virgei annuli. But *Turnebus* readeth *Virgæ Jaculi*, i. ſtaves or Iavelines made of their ſtreit boughes. And, *Expertes ferri*, i. not headed with yron.

Chap. xxx.

Of the Lawrell or Bay tree, thirteene kinds thereof.

LAwrell is appropriate unto triumphs, and beſides groweth moſt pleaſantly before the gates of the Emperors court, and Biſhops pallace; giving attendance there as a dutifull portreſſe or huiſſer, moſt decently. This tree alone both adorneth their ſtately houſes, & alſo keepeth, watch and ward duly at the dores. *Cato* ſetteth downe two kinds of Lawrell, to wit, the Delphicke, and the Cyprian. Hereunto *Pompeius Lenæus* hath joined a third, which he called Muſtacea; becauſe in old time they uſed to lay the leaves thereof under certaine cakes or March-panes (which in thoſe daies they called Muſtacea) as they were in baking: This third kind hath leaves of all others largeſt, flaggie, hanging, and whitiſh withall. As for the Delphick, it carieth leaves of one entire colour, greener than the reſt: the baies or berries thereof likewiſe are biggeſt, and of a reddiſh greene colour. With this Lawrell were they wont to be crowned at Delphos, who woon the priſe at any tournoy or ſolemne games; as alſo the victorious captains who triumphed in Rome. The Cyprian Lawrell hath a ſhort leafe, blacke, criſped, or curled, and about the ſides or edges thereof it turneth up hollow like a gutter or creſt-tile. Howbeit, afterwards there were raunged in the ranke of Lawrels other trees, to wit, the Tinus, which ſome take to be the wild Lawrell, others ſay it is a kind of tree by it ſelfe: indeed, it differeth from other Lawrels in the colour of the fruit; for it beareth blew berries. Then came the roiall Lawrell in place, which began to be called Auguſta or Imperiall. This is a very tall and big tree, with leaves alſo as large in proportion, and the Baies or Berries that it beareth are nothing ſharpe biting and unpleaſant in taſt. But ſome there be that thinke this roiall Bay, is not a Lawrell, but a ſeverall tree apart, as having longer and broader leaves than the reſt of the ordinarie ſort. And theſe writers ſpeaking of other kinds, call our common Bay tree, Baccalia, and namely that which is ſo fruitfull and beareth ſuch a ſort of Berries: as for the fruitleſſe and barren of that ſort they name Triumphall, which, as they ſay, is uſed in triumphs. Whereat I marvell very much, unleſſe this ordinance and cuſtome began of *Auguſtus Cæſar*, by occaſion of that Lawrell which came to him as ſent from heaven (as I wil ſhew anon more at large;) and of all others it is for height loweſt, in leafe ſhort and frizled, very geaſon and hard to be found. Now there is another kind of Lawrell named Taxa, very fit for greene arbors, and to be wrought into knots. Out of the middeſt of the leafe there groweth foorth another little one, in manner of a skirt, tongue, or lappet of the leafe. Alſo without any ſuch excreſſence, there is that, which they name Spadonia, as one would ſay, the guelded Bay, which careth not how ſhadowie the place be where it groweth: for be it never ſo remote out of the Sunne, or overſhadowed howſoever, yet it ceaſeth not to grow and overſpread the ground where it ſtandeth. Moreover in this rank is to be reckoned the wild ſhrub called Lowrier or Chamædaphne. There is beſides the Lawrell Alexandrina, which ſome call Idæa, [i. Mountaine Lawrell] others Hyppoglottion, [i. Horſe-tongue] ſome Daphnitis, others Carpophyllon or Hypelate. This plant putteth forth

braunches

A braunches immediately from the root, of a ſpan or nine inches long: very proper and handſome to draw workes, or to clad arbours withall in a garden, alſo to make guirlands and chaplets. The leaves are more ſharpe and pointed, ſofter alſo and whiter than thoſe of the Myrtle, yea, & have within them a bigger grain or ſeed, of colour red. Great plentie therof groweth upon the mountaine Ida, likewiſe about Heraclea in Pontus: and in one word, never but in hillie and mountaine countries.

As for the hearbe Daphnoeides or Laureola, it hath many names. For ſome tearme it Pelaſgum, others Eupetalon, and there are againe who would have it to be Stephanos Alexandri [*i. Alexanders* chaplet.] This plant alſo is full of branches, carying a thicker and ſofter leafe than the common Lawrell: and if a man taſt therof, it will ſet both the mouth and alſo the throat on a fire:
B the berries that it beareth be blackiſh, inclining to a kind of red. It hath been noted and obſerved in auncient writers, that no kind of Lawrell in old time was to be found in the Iſland Corſica: and yet in theſe daies it is there planted, and thriveth well ynough. The Lawrell betokeneth peace: inſomuch, as if a braunch thereof be held out among armed enemies, it is a ſigne of quietnes and ceſſation from arms. Moreover, the Romans were wont to ſend their miſſive letters adorned with Lawrell, when they would give advertiſement of ſome ſpeciall good newes or joifull victorie: they uſed beſides to garniſh therewith their launces, pikes, and ſpeares. The knitches alſo & bunches of rods, borne before grand captaines and generals of the armie, were beautified and ſet out with Bay branches. Herewith they ſticke and bedecke the boſome of that moſt great and gracious *Iupiter*, ſo often as there commeth glad tidings of ſome late and freſh victorie. And all this
C honor is done to the Lawrell, not becauſe it is alwaies greene, nor for that it pretendeth and ſheweth peace (for in both theſe reſpects the olive is to be preferred before it) but in this regard, That the faireſt and goodlieſt of them grow upon the mountaine Pernaſſus: and therefore alſo is it ſo acceptable to *Apollo*, for which cauſe (as may appeare by *L. Brutus*) the Roman kings in old time were accuſtomed to ſend great preſents and oblations thither to the temple of *Apollo*: or peradventure it was in memoriall of that ground that bare Lawrell trees, and which according to the Oracle of *Apollo*, the ſaid *L. Brutus* kiſſed, when he intended the publicke freedome of the cittie, and minded to deliver it from the yoke and ſervitude of the kings: or haply, becauſe it alone either ſet with the hand before the dores, or brought into the houſe, is not blaſted and ſmitten with lightning. And theſe reaſons verily induce me to beleeve, that in times paſt they choſe the
D Bay tree for their triumphs, before any other: rather than as *Maſſurius* would have it, becauſe the Lawrell ſerved for a ſolemne perfume, to expiate and aſſoile the carnage and execution done upon the enemies. And ſo farre were men in old time from common uſing either Lawrell or Olive, & polluting the ſame in any prophane uſe, that they could not be permitted to burn thereof upon their altars when they ſacrificed or offered Incenſe, although it were to doe honor to the gods, and to appeaſe their wrath and indignation. Evident it is, that the Bay tree leaves, by their crackling that they make in the fire, doe put it from them, and ſeeme to deteſt and abhorre it. It cureth moreover the diſeaſes of the guts [the Matrice and the Bladder] alſo the laſſitude and wearineſſe of the ſinewes. It is reported, that *Tiberius Cæſar* the Emperor uſed ever to weare a chaplet thereof when it thundered, for feare of being ſtrucken with lightening.

E Moreover, certaine ſtrange and memorable events as touching the Bay tree, have happened about *Auguſtus Cæſar*. For *Livia Druſilla*, (who afterwards by mariage with the ſaid *Auguſtus*, became Empreſſe, and was honoured with the title of *Auguſta*) at what time as ſhe was affianced and eſpouſed to *Cæſar*, chaunced as ſhe ſat ſtill, to have an exceeding hote Hen to light into her lap (which an Ægle flying aloft, let fall from on high) without any harme at all to the ſaid pullet. Now when this ladie or princeſſe adviſed and conſidered well the Hen, without being aſtonied & amazed at ſo ſtrange and miraculous a ſight, ſhe perceived that the Hen held in her bill a Lawrell, branched full of Bay berries. The Wiſards and Soothſaiers were conſulted withall about this wonderfull occurrent, and gave adviſe in the end to preſerve the bird and the brood therof: likewiſe to ſet in the ground the foreſaid braunch, and duly to tend and looke unto it. Both the one
F and the other was done and executed accordingly, about a certaine houſe in the countrie belonging to the *Cæſars*, ſeated upon the river Tyberis, neare the cauſey or port-way Flaminia, about nine miles from Rome: which houſe therupon was called, Ad Gallinas, as a man would ſay, The ſigne of the Hens. Well, the foreſaid braunch mightily proſpered, and proved afterwards to be a grove of Lawrels, which all came from that firſt ſtocke. In proceſſe of time, *Auguſtus Cæſar* when

he

he entred in Triumph into Rome, caried in his hand a braunch of that Bay tree, yea, and wore a chaplet upon his head of the same: and so did all the Emperours and *Cæsars* his successors after him. Hereof also came the custome to set againe and replant those braunches of Lawrell that Emperors held in their hands when they triumphed: & thereof continue whole woods & groves distinguished each one by their severall names, and perhaps therefore were they named Triumphall. This is the onely tree knowne in the Latine tongue, whereof a man beareth the name. Againe, there is not another tree besides that hath the leafe to carie in the Latine tongue a denomination and name by it selfe apart, as well as the tree; for where as the plant is named Laurus, the leafe we call Laurea. Moreover, there is a place likewise within the citie of Rome upon mount Aventine, retaining still the name Loretum, which first was imposed upon it by reason of a Lawrell grove which grew there. The Bay tree also is used in solemne purifications before the gods: and to conclude, this would be resolved and agreed upon by the way, That if a branch thereof be set, it will prosper and become a tree; although *Democritus* and *Theophrastus* make some doubt thereof. Thus much of Lawrels and other domesticall and native trees: it remaineth now to write of those that be wild and savage, and of their natures.

THE XVI. BOOKE OF THE HISTORIE OF NATVRE,

WRITTEN BY C. PLINIVS SECVNDVS.

The Proëme.

Hitherto have we treated of those Trees that beare Apples and such like fruits: which likewise with their mild juice and sweet liquors made our meats first delightsome, and taught us to mingle together with the necessarie food for sustentation of our lives, that which maketh it delicate and pleasant to content our tast: as well those trees that naturally were so in the beginning, as those which through the industrie and skill of man, what by graffing and what by wedding them (as it were) to others, became toothsome, and delectable to our tongue: whereby also wee have gratified in some sort wild beasts, and done pleasure to the foules of the aire. It followeth now by order, that we should discourse likewise of trees that beare Mast, those trees (I say) which ministred the first food unto our forefathers, and were the nourices that fed and cherished mankind in that rude wild age and poor infancie of the world: but that I am forced to breake the course of mine historie, and prevented with a deepe studie and admiration arising from the truth and ground of experience, to consider, What manner of life it might be, to live without any trees or shrubs at all growing out of the earth.

Chap. 1.

Of nations that have no trees nor plants among them. Of wonderfull trees in the Northerly regions.

WE have shewed heretofore, that in the East parts verily toward the maine Ocean, there be many countries in that estate, to wit, altogether destitute of trees. In the North also I my selfe have seene the people called *Cauchi, as well the greater as the lesse (for so they be distinguished) where there is no shew or mention at all of any tree. For a mightie great compasse, their countrey lieth so under the Ocean,

*i. The low countries of Zeland, &c.

and

and ſubject to the tide, that twice in a day & night by turnes, the ſea overfloweth a mightie deale of ground when it is floud, & leaveth all drie again at the ebbe & return of the water: inſomuch, as a man can hardly tell what to make of the outward face of the earth in thoſe parts, ſo doubtfull it is between ſea and land. The poore ſillie people that inhabit thoſe parts, either keepe together on ſuch high hils as Nature hath afforded here & there in the plain: or els raiſe mounts with their owne labour and handie worke (like to Tribunals caſt up and reared with turfe, in a campe) above the height of the ſea, at any Spring tide when the floud is higheſt; and thereupon they ſet their cabines and cottages. Thus dwelling as they doe, they ſeeme (when it is high water, & that all the plaine is overſpread with the ſea round about) as if they were in little barkes floting in the middeſt of the ſea: againe, at a low water when the ſea is gone, looke upon them, you would take them for ſuch as had ſuffered ſhipwracke, having their veſſels caſt away, and left lying ato-ſide amid the ſands: for yee ſhall ſee the poore wretches fiſhing about their cottages, and following after the fiſhes as they go away with the water. They have not a four-footed beaſt among them: neither enjoy they any benefite of milke, as their neighbour nations doe: nay, they are deſtitute of all meanes to chaſe wild beaſts, and hunt for veniſon; in as much as there is neither tree nor buſh to give them harbour, nor any neare unto them by a great way. Sea-weeds or Reike, ruſhes and reeds growing upon the waſhes & meeres, ſerve them to twiſt for cords to make their fiſhing nets with. Theſe poore ſoules and ſillie creatures are faine to gather a ſlimie kind of fattie mud or oaſe, with their very hands, which they drie againſt the wind rather than the Sunne: and with that earth, for want of other fewell, they make fire to ſeeth their meat (ſuch as it is) and heat the inward parts of their bodie, readie to bee ſtarke and ſtiffe againe with the chilling North wind. No other drinke have they but raine water, which they ſave in certaine ditches after a ſhower, and thoſe they dig at the very entrie of their cottages. And yet ſee! this people (as wretched and miſerable a caſe as they bee in) if they were ſubdued at this day by the people of Rome, would ſay (and none ſooner than they) that they lived in ſlaverie. But true it is, that Fortune ſpareth many men, to let them live ſtill in paine and miſerie. Thus much as touching want of woods and trees.

On the other ſide, as wonderfull it is to ſee the mightie forreſts at hand thereby, which overſpread all the reſt of Germanie: and are ſo big, that they yeeld both cooling and ſhade to the whole countrey. Yea, the very talleſt woods of all the reſt are a little way up higher in the countrey, and not farre from the Cauchi aboveſaid: and eſpecially thoſe that grow about the two great loughes or lakes in that tract. Vpon the bankes whereof, as alſo upon the ſea-coaſts, there are to be ſeene thicke rowes of big Okes, that love their ſeat paſſing well, and thrive upon it in growth exceeding much: which trees happening to be either undermined by the waves and billowes of the ſea under them, eating within their roots, or chaſed with tempeſtuous winds beating from above, carie away with them into the ſea (in manner of Iſlands) a great part of the Continent, which their roots doe claſpe and embrace: wherewith being counterpoiſed and ballaiſed, they ſtand upright, floting and making ſaile (as it were) amid the waves, by the meanes of their mightie armes which ſerve in ſtead of tackling. And many a time verily, ſuch Okes have frighted our fleets and armadoes at ſea: and eſpecially in the night ſeaſon, when as they ſeemed to come directly againſt their proes ſtanding at anker, as if of purpoſe they were driven upon them by the waves of the ſea: inſomuch, as the ſailers and paſſengers within, having no other meanes to eſcape them, were put to their ſhifts, and forced for to addreſſe themſelves, and range a navall battell in order, and all againſt trees, as their very enemies.

Chap. II.

Of the huge and great forreſt Hercynia.

IN the ſame North climate is the mightie forreſt Hercynia. A huge and large wood this is, ſtored with tall and big Okes, that never to this day were topt or lopt. It is ſuppoſed they have beene ever ſince the creation of the world, and (in regard of their eternall immortalitie) ſurmounting all miracles beſides whatſoever. And to let paſſe all other reports which happily would be thought incredible, this is knowne for certaine, That the roots of the trees there, run and ſpread ſo farre within the ground, that they encounter and meet one another: in which reſiſtance they ſwell and riſe upward, yea, and raiſe up mounts of earth with them to a good height in

in many places: or, where as the earth followeth not, a man shall see the bare roots embowed arch-wise, and mounting aloft as high as the very boughes: which roots are so interlaced, or else rub one against the other, striving (as it were) not to give place, that they make a shew of great portailes or gates standing open so wide, that a whole troupe or squadron of horsemen may ride upright under them in ordinance of battell.

Chap. iii.

Of trees bearing Mast.

MAst trees they were all, for the most part, which the Romanes ever so highly honoured and held in best account.

Chap. iiii.

Of the Civicke guirland: and who were honoured with chaplets of tree-leaves.

FRom Mast trees [and the Oke especially] came the Civicke coronets. And in very truth, these were the most honourable badges and ornaments that could possibly bee given unto souldiours and men of warre, in regard of their vertue and manhood: yea, and now for a good while, our Emperours have had this chaplet graunted unto them, in token and testimonie of clemencie: ever since that by our prophane and unkind civile warres the world is growne to this passe, that it is reputed a singular demerite and gracious act, not to kill a cittizen of Rome, but to let him live. To this kind of guirland, none other be comparable: for the Murall and Vallare coronets (bestowed upon them that either skaled the walls, or entred the breach first into an enemie citie, or else mounted over the rampier of a campe) albeit they were of gold, and of greater price by farre, yet they gave place to these. Yea, the very Navall coronets, fashioned like the three forked pikes of ship beake-heads (wherwith they were honoured, who had performed some brave service at sea) came behind these Civick guirlands, due to them who have rescued citizens and saved them out of the enemies hands: and yet in these our daies there have beene knowne twaine in that kind most renowmed above the rest; whereof the one was bestowed upon *M. Varro*, by *Pompey* the Great, for defeating the pyrates, and for scouring & clearing the seas of them: the other likewise given to *M. Agrippa*, by [*Augustus*] *Cæsar*, for vanquishing the Sicilians, who also were no better than rovers.

Now for as much as we are light upon the mention of Navall or Rostrate coronets, this would be noted, That in old time the said brasen beake-heads of ships woon from the enemies, and set upon the front of the Tribunall or publicke pulpit in Rome, served for an ornament to beautifie the Forum or common place of the citie; so as the very bodie of the people of Rome seemed to be crowned and honoured thereby. But after that the Tribunes in making seditious Orations, began to stampe and fare like mad men there, to trample (I say) under foot, and to pollute that sacred place and those goodly ensignes; after that they fell once every man to make his privat and particular profit of the common good, without regard to advance the weale publicke; after that each one sought to strengthen and arme himselfe by the benefite of authoritie, and that to the weakening of the maine state, insomuch as they who were reputed by their place sacrosanct and inviolable, polluted and prophaned all: then the said ornaments of beake-heads, which beautified the place under their feet, served to adorne the heads of Romane cittizens. So as, to returne againe now to the abovenamed *Agrippa*, *Augustus Cæsar* gave unto him a Navall coronet for subduing the Sicilian pyrates: and himselfe received of mankind a Civicke chaplet, for sparing the bloud, and saving the lives of so many citizens.

In auncient time they used to crowne none but the gods. And hereupon it is, that the Poët *Homer* speaketh of no guirlands and chaplets but due to the celestiall & heavenly wights, or at leastwise in the name of a whole armie, for victorie atchieved in some notable battell: for to one man alone hee alloweth not any, no not in regard of the better hand in combate or single fight. And to say a truth, the first that ever set a guirland upon his owne head, was prince *Bacchus*, and the same was made of Ivie: but afterwards, those that sacrificed to the honor of gods, not only ware chaplets themselves, but also adorned therewith the heads of the very beasts which were appointed to be killed for sacrifice. In the end, the custome was taken up to honor them with

guir-

guirlands, who wan prizes at thoſe ſacred and ſolemne games, Olympia, Iſthmia, Pythia, and Nemœa. Howbeit the manner was then, and ſo continueth to this day, To give chaplets to the ſaid victours, not in their owne name, but in the behalfe of their native country, which by open proclamation they pronounce to be crowned and honoured thereby. And hereof it came alſo, that ſuch coronets and chaplets were graunted to them that ſhould triumph, yea and ſoon after to thoſe alſo who had woon the prize in any publick games, upon condition to dedicate them to the temple of the gods.

To diſcourſe what Romane cittizen received this honour firſt of a chaplet or coronet, were a long peece of worke, and nothing pertinent to our purpoſe and matter in hand; conſidering that they were acquainted with none at all, but in regard of ſervice performed in the warres. Yet thus much I may averre for certein, That no nation under heaven, nay put them all togither, can ſhew ſo many ſorts of chaplets and coronets, as this one ſtate and people of Rome. K. *Romulus* crowned *Hoſtus Hoſtilius* with a guirland of bare greene leaves, for that in the forcing and ruining of Fidena, he brake firſt into the citie and made way for the reſt. This man was grandſire to *Tullus Hoſtilius* king of Rome. Semblably in the warre againſt the Samnites, wherein *Cornelius Coſſus* the Conſull was L. Generall, the whole armie crowned *P. Decius* the father with a chaplet of greene leaves, who then was a martiall Tribune or Colonell over a regiment of ſouldiors, for that he had ſaved and delivered the ſaid armie.

But now to come againe to our Civicke guirland, it was made at firſt of the Ilex or Holme tree leaves: afterwards men tooke a better liking to make it of the Æſculus, a tree conſecrated to *Iupiter*. They ſtaied not there, but chaunged ſoone after with the common oke; neither made they any preciſe choiſe, but tooke the leaves of that which came next hand, whereſoever they found it growing; provided alwaies that it bare acorns: for all the honour of theſe guirlands conſiſted principally in the maſt. Moreover, there belong to theſe Civicke guirlands ſtreight lawes and ordinances, in which regard theſe chaplets be proud and ſtately: and wee may be bold to compare them with that Paragon-coronet of the Greekes, which paſſeth all others, given ſolemnly and publiſhed in the preſence of *Iupiter*, and made of the wild Olive dedicated unto him: comparable (I ſay) to any crowne or chaplet whatſoever; even to that, for which a citie in token of joy, would not ſticke to lay open a * breach in their very wall to receive it when it ſhould enter in. The lawes ordained in this behalfe run in this forme. *Imprimis, Hee that is to enjoy the honour of a Civicke chaplet, ought, Firſt, To have reſcued a cittizen, and withall to kill the enemie in whoſe daunger he was. Item, It is required, that the enemies the ſame day held the very ground and were maſters hereof, wherein the reſcue was made and the ſervice performed. Item, That the partie himſelfe ſo ſaved, doe confeſſe the thing, for otherwiſe all the witneſſes in the world availe not in this caſe. Item, The man thus delivered, muſt be a free citizen of Rome in any hand: for ſet caſe that hee were a king which was thus reſcued, if he were a ſtraunger, and came onely among the auxiliaries to aid the Romans, it would not boot, nor gaine any man this honour for to ſave his life. Item, Say that the Generall himſelfe were reſcued and delivered out of daunger, the partie for his good ſervice ſhould have no more honour done unto him, than if he had preſerved but a ſimple common ſouldior, ſo hee were a Romane citizen: for the makers of theſe ordinances aimed chiefly at the life of a citizen whoſoever he was, without regard of any other circumſtance. Item, Hee that was once crowned with this guirland, was endued alſo with theſe priviledges: That he might weare it alwaies after, whenſoever it pleaſed him: That ſo often as he came in place of publicke plaies or games, men ſhould accuſtomably riſe up unto him, yea and the very Senators themſelves, doe him honour in that ſort: That he ſhould have his place allowed him to ſit next to thoſe of Senators degree: That both himſelfe, and alſo his father and grandſire by the fathers ſide, ſhould ever after be exempt from all civile charges and enioy full immunitie.* Thus much concerning the lawes and priviledges attending upon the Civicke guirland. *Siccius Dentatus* (as we have ſpecified before) received fourteen of theſe chaplets for his good ſervice: [*Manlius*] *Capitolinus* ſix, and he verily had one of them for reſcuing *Servilius* being Generall of the armie. As for *Scipio Africanus*, he refuſed this honour when it was offered and preſented unto him, for ſaving the life of his own father at the journey and battaile of Trebia. O the excellent orders & cuſtoms of thoſe times, worthie of immortalitie & everlaſting memorie! ô the wiſdome of men in thoſe daies, who aſſigned no other reward for ſo brave exploits and ſingular works, but honor only! and wheras all other militarie coronets they enriched and adorned with gold, they would not ſet the life of a citizen at any price. A plaine and evident

* As the manner was to receive the Hieronicæ.

profession of our aunceſtors and predeceſſours, That it is an unlawfull and ſhamefull thing to ſeeme for to ſave a mans life, in hope of any gaine and profit thereby.

Chap. v.

Of Maſt, thirteene kinds.

MAny nations there be even at this day, and ſuch as enjoy peace and know not what warre meaneth, whoſe wealth and riches lyeth principally in Maſt: yea and elſewhere in time of dearth and for want of other graine, folke uſe to drie their maſt, grind it into meale, temper it with water, and thereof make dough for bread. Moreover, even at this day throughout Spaine, the manner is to ſerve up acorns and maſt to the table for a ſecond ſervice: & ſweeter it is being roſted under the cinders and aſhes, than otherwiſe. Over and beſides, provided it is by an expreſſe act and law of the twelve tables in Rome, That a man may gather the maſt that falleth from his owne trees into another mans ground.

Divers and ſundrie ſorts there be of Maſt, and their difference conſiſteth in the forme and faſhion of the fruit, in the ſite and ſituation of the place, in the ſex, and in the taſt: for the maſt of the Beech tree is of one figure and making, the Acorne (which is the maſt of the Oke) another; and the maſt of the Holme or Ilex, differeth from them both: yea & in every one of theſe kinds, they doe varie one from another. Alſo, ſome are of trees growing wild; others more mild and gentle, loving places well tilled and ordered by husbandrie. Some like the hillie countries, others the champaine and the plaines. Semblably there is maſt comming from the male trees: there is again that groweth on the female. In like manner, the relliſh and taſt maketh a difference and diverſitie in maſt. The ſweeteſt of all, is the Beech maſt: for *Cornelius Alexander* reporteth, That the inhabitants of Chios, when they were ſtreightly beleaguerd, endured the ſiege a long time by the benefit and ſubſtance onely of the maſt. We are not able diſtinctly to ſpecifie name by name, the ſundrie ſorts of maſt and the trees which beare the ſame, conſidering that in everie countrey they alter their names: for wee ſee the Robur and the Oke to grow commonly everie where, but the Eſculus is not ſo rife in all countries. A fourth ſort there is of the ſame kind, which is not knowne ordinarily in moſt places of Italy. We will therefore diſtinguiſh them according to their nature and properties: yea and when need ſhall require, by their Greeke names alſo.

Chap. vi.

Of the Beech maſt, and other Maſts: of Charcole: and the feeding of Hogs.

THe Beech maſt is like to the kernell of a Cheſtnut, encloſed within a three-cornered skin. The leafe of the tree is thin and very light, reſembling that of the Poplar: it turneth yellow paſſing ſoone. In the middle whereof, for the moſt part, and in the upper ſide, it bringeth forth a little greene berrie, pointed ſharpe at the top. The maſt of Beech, Rats and Mice are much delighted in: marke therefore when there is ſtore of that maſt, yee ſhall have as great encreaſe of that vermin. It will feed alſo Reremice or Dormice fat: and the Ouſels or Blackbirds take a great liking thereto, and will flie unto it. Lightly, all trees are more fruitfull one year than another, and beare moſt every ſecond yeare; but above all, Beeches keepe this courſe. As touching Maſt (which properly is ſo called) it groweth upon the Robur, the common Oke, the Eſculus, Cerrus, Ilex, and Corke tree. All kinds of maſt are conteined more or leſſe, within a rough cup, which lieth cloſe to the utmoſt skin thereof, & claſpeth it about. The leaves of all theſe maſt trees, except the maſt-Holme Ilex, be heavie, fleſhie, large, waved or indented along the ſides, neither be they yellow when they fall, as the Beech leaves are; longer alſo or ſhorter, according to the divers trees whereupon they grow.

Of the Ilex or maſt-Holme tree, there be two ſorts. Thoſe in Italy differ not much in leafe from the Olive. Some Greekes call them Smilaces, but in other provinces Aquifoliæ. The maſt of Ilex, both the one and the other, is ſhorter and ſlenderer than of the reſt: *Homer* calleth it Acylon, by which name he diſtinguiſheth it from other maſt. The male Holms (men ſay) beare no fruit. The beſt maſt and the biggeſt, is the Acorne growing upon the common Oke: next to it is that of the Eſculus: as for that of the Robur, it is but ſmall. The Cerrus carrieth a maſt unpleaſant to the eie, and rough to be handled, for clad it is with a cup beſet with ſharpe pricks like

to

A to the Cheſtnut ſhell. Among the very Acornes, ſome have a ſweeter taſt than others: the female Oke beareth thoſe that be more ſoft and tender; the male, tough, thicke, and maſſie: and the beſt ſimply are thoſe that come of the broad-leafed Oke, for ſo it is called by reaſon of the large leaves. Moreover, there is another difference in maſt and acorns, for ſome be bigger than others; again, there are that have thin & fine skins encloſing the kernell; and ye ſhall find others for them as thicke skinned; likewiſe many of them are covered with a rough and ruſtie tunicle; and as many againe do ſhew immediatly their bare white skin and naked fleſhie ſubſtance. Furthermore, that maſt is accounted good, which at both ends (taking it long-waies) groweth hard in manner of a ſtone: howbeit that which hath an hard ſhell without, and a ſoft bodie within, is better than that which is hardened in the carnous ſubſtance of the bodie; and lightly neither of
B both theſe qualities happeneth to any but the male kind. Over and beſides, ſome you ſhall find faſhioned long like an egge; others as round as a ball; and a third ſort ſharpe pointed. The outward colour alſo yeeldeth varietie: for ſome be blacker than other, but the whiter commonly be the better ſet by. Some are bitter toward the ends, and ſweet in the mids. The length alſo & the ſhortneſſe of the ſtele or taile whereto they hang, maketh a difference. The very tree it ſelfe cauſeth diverſitie of the fruit: for that oke which beareth the biggeſt maſt, is named Hemeris. A ſhorter tree this is than the reſt, with a round head, and putting foorth many hollow armepits (as it were) of boughs and braunches. The wood or timber of the ordinarie and common Oke is tougher and harder than that of others, and leſſe ſubject to putrefaction: full of arms & boughs it is, as the other, but it groweth taller and is thicker in the bodie. The higheſt of all, is the Ægi-
C lops, which loveth to grow in wild and deſart places. Next to it for talneſſe, is the broad leafed Oke, but the timber thereof is not ſo good and profitable for building, howſoever it be emploied for to make charcole: yet being once ſquared to that purpoſe, & cleft, it is ſubject to the worme, and will ſoone rot: and for this cauſe, being in quarters, they uſe not to make cole of it cloven, but of the ſolid and round boughs or braunches thereof. And yet this kind of charcole ſerveth onely the Bloome-ſmithies and furnaces; the hammer-mils alſo of braſſe and copper-ſmiths, whome it ſtandeth in great good ſtead and ſaveth them much fewell; for it burneth and conſumeth no longer than the bellowes goe: let them leave blowing once, preſently the cole dieth; and ſo it laſteth long: for at every new blaſt it is renewed againe and refreſhed: otherwiſe it ſparkleth very much and yeeldeth many cinders. But the charcole made of yong trees is the better.
D Now the manner of making them, is this: when the wood is cut into many clefts & ſplents, freſh and green, they are heaped up on high, and hollow, in manner of a furnace or chimney, and then well luted with clay in the top, and all about: which done, the pile of truncheons aforeſaid, is ſet on fire within; and as the outward coat or cruſt of clay beginneth to wax hard, the workemen or colliars pierce it with poles and pearches, and make divers holes therein for vent, and to let out the ſmoakie vapour that doth ſweat and breath from the wood. The worſt of all other for timber or cole, is the oke named Haliphleos; a thicke barke it hath, and as big a bodie, but for the moſt part hollow and light like a ſpunge or muſhrome: and there is not another beſides it of all theſe kind of trees, that rotteth as it ſtands alive. Beſides, ſo unfortunate it is, that the lightning ſmiteth it, as low as it groweth; for none of them ariſeth to any great height: which is the
E cauſe that it is not lawfull to uſe the wood thereof about the burning of any ſacrifice. Seldome beareth it any Acorns, and thoſe few that it hath, be exceeding bitter, ſo as no other beaſt will touch them, but ſwine again; nor they neither, but for pure hunger, when they can meet with no other food. Moreover, in this regard alſo rejected it is, and not emploied in any religious uſe, for that without blowing at the wood and cole thereof continually, it will not burne cleare and conſume the ſacrifice, but goeth out and lieth dead.

But to returne unto our maſt againe: That of the Beech tree feedeth ſwine quickly, maketh their fleſh and lard faire and pleaſant to the eye, tender to be ſoone ſodden or roſted, light and eaſie of digeſtion, and good for the ſtomacke. The maſt of the Holme cauſeth hogs to gather a more faſt and compact fleſh, their bodies to be neat, ſlender, lanke, and ponderous. Acorns doe engender a fleſhie ſubſtance, more ſquare and ſpreading, and the ſame alſo moſt heavy and hardeſt of digeſtion, and yet they are of all other kinds of maſt, moſt ſweet and pleaſant. Next to them in goodneſſe (by the teſtimonie of *Nigidius*) is that of the tree Cerrus, neither is there bred of any other a courſer fleſh, howbeit hard it is, faſt, and tough. As for the maſt of Ilex, hogs are endaungered by eating thereof, unleſſe it be given them warily by little and little. Hee ſaith

moreover, that of all other it falleth laſt. Moreover, the maſt of Eſculus, Robur, and the Corke, cauſeth the fleſh to be ſpungeous and hollow. To conclude, what trees ſoever beare maſt, carrie alſo certaine nuts called Galls: and lightly they are full of maſt but each other yeare. But the oke Hemeris beareth the beſt galls, and fitteſt for the curriours to dreſſe their leather. The broad leafed oke hath a kind of galls like unto it, but lighter in ſubſtance, and not ſo good by far: it carieth alſo blacke galls (for two ſorts there be) and this is better for the dier to colour wooll.

Chap. vii.

Of the Gall-nuts: and how many other things Maſt-trees doe beare beſides Maſt.

THe nuts called Galls, doe ever breake out all at once in a night, and namely about the beginning of Iune, when the ſunne is readie to goe out of the ſigne Gemini. The whiter ſort thereof commeth to the growth in one day: and if in the firſt ſpring and breaking foorth thereof it be hot weather, it drieth and withereth out of hand, and commeth not to the full bigneſſe and perfection, namely to have a kernell as much as a Beane. The blacke of this kind continueth longer freſh and greene, and groweth ſtill, to the bigneſſe otherwhiles of an apple. The beſt Galls be thoſe of Comagena: the worſt is that of the oke called Robur, which are knowne by the holes they have, that may be ſeen through. The common oke Quercus, over and beſides the fruit (which is the maſt) beareth many other things; for it carieth both ſorts of Gall, the black and the white: certaine berries alſo like Mulberries, but that they be drie and hard, reſembling for the moſt part a Bulls head, conteining within them a fruit much like the kernels of the Olive. Moreover, there grow upon it certain little balls not unlike to nuts, having ſoft flox within good to make candle-wieke or matches for lamps; for burn they will without any oile, like as the black Galls. It beareth alſo other little pills or balls good for nothing, covered over with haire, & yet in the ſpring time they yeeld a certain juice or liquor like honey. Furthermore, there breed in the hollow arme-pits (as it were) of the boughs, other ſmall pills ſetled or ſticking cloſe to the wood, and not hanging by any ſteles, which toward the navill or bottome thereof are whitiſh; otherwiſe they be ſpeckled all over with blacke ſpots, ſave that in the mids betweene they are of a ſcarlet red colour: open them, and hollow they are within, but very bitter. Sometimes alſo this Oke engendreth certain hard calloſities, like Pumiſh ſtones; yea and other round balls made of the leaves folded one within another: on the backeſide alſo of the leafe where it is reddiſh, yee ſhall find ſticking certaine wateriſh pearls, white and tranſparant or cleare within, ſo long as they be ſoft and tender; wherein there breed little flies or gnats: howbeit in the end they ripen and wax harder, in manner of Galls.

Chap. viii.

Of the Catkin called Cachrys: the graine of Scarlet: of Agaricke, and Corke.

THe Oke called Robur, bringeth forth likewiſe a certaine pendant chat or catkin, named in Greeke Cachrys: for ſo they tearme the little pill, which is of a burning and cauſticke nature, and whereof there is uſe in Phyſicke for potentiall cauteries. The like groweth upon Firres, Larch trees, Pitch trees, Lindens or Tillets, Nut-trees, and Planes, namely after that the leaves be falne; and abideth upon the tree in winter time. Theſe chats have a kernell within like to thoſe of the Pine-nuts. It beginneth to grow in winter, and by the ſpring time all of it openeth and ſpreadeth to the proofe; but when the leaves begin to bud and put forth, it falleth off. Thus you ſee how fruitfull theſe Okes be, and how many things beſides maſt, they do bring forth. And yet they ceaſe not nor give over thus, for many times a man ſhall ſee certaine excreſcences growing forth about their roots, ſuch as toadſtools and muſhroms; the laſt deviſes that our gluttons have invented to whet their appetite and ſtomacke, and to maintaine gourmandize. The common Oke breedeth the beſt of this kind: as for thoſe that grow about the Oke Robur, the Cypreſſe, and Pine tree, they are hurtfull to be eaten and venomous. Moreover, *Heſiodus* ſaith, that the Okes Robora do beare Miſſelto, and yeeld honey. True it is indeed, that the honey-dews called Manna, falling from heaven (whereof we have ſpoken before) light not upon any other leaves

leaves more than of thoſe Okes. Moreover, this is knowne for certain, that the aſhes of this oke when it is burnt, hath a qualitie or taſt of nitre or ſalt-peter.

Howbeit for all the riches and fruit that the Oke affourdeth, the Scarlet graine alone which commeth of the Ilex, challengeth yea and overmatcheth it. This graine is no other than a verie excrement or ſuperfluitie ariſing about the ſtem of the ſmall ſhrub called Ilex Aquifolia, ſcraped and pared off from it, like ſuch refuſe as they call Cuſculium or Quiſquilium: but of ſuch price it is, that the poore people of Spaine gather it, & make a good part of their revenew thereby, even as much as will pay halfe their tribute. As touching the commendable uſe thereof in dying, wee have ſufficiently ſpoken in the diſcourſe of the purple tincture. This ſcarlet graine is engendred alſo in Galatia, Africa, Piſidia, and Cicilia. But the worſt of all other is that which commeth out of Sardinia.

As for Agaricke, it groweth in Fraunce principally upon trees that beare maſt, in manner of a white muſhrom: of a ſweet ſavor, very effectuall in Phyſicke, and uſed in many Antidotes and ſoveraigne confections. It groweth upon the head and top of trees: it ſhineth in the night, and by the light that it giveth in the darke, men know where and how to gather it.

Of all Maſt-trees, the Oke called by the Greekes Ægylops, beare certaine drie excreſcences ſwelling out like touchwood, covered all over with a hoarie and haitie moſſe, and theſe not onely beare out from the barke of the fruit, but alſo hang downe from the boughs a cubit in length: and odoriferous they are, as we have ſhewed in our treatiſe of Ointments.

Now concerning Corke, the woodie ſubſtance of the tree is very ſmall, the maſt as bad, hollow, ſpongeous, and good for nothing. The barke onely ſerveth for many purpoſes, which will grow again when the tree is barked, and that of ſuch a thicknes, that it will beare ten foot ſquare. Much uſe there is of it in ſhips, & namely for boys to ancre cables; alſo for flotes to trainels or dragnets that fiſhers doe occupie: moreover in bungs and ſtopples of barrels, bottles, and ſuch like veſſels. Finally, our gentlewomen and daintie dames have the ſoles of their pantofles and winter-ſhoes underlaid therewith. In regard of which barke, the Greekes call it by a prety name, and not improperly, The Barke tree, or the tree all barke. Howbeit ſome would have it to be the female Ilex or maſt-Holm, and ſo they name it: and where there groweth no Ilex, in ſtead thereof they take Corke, eſpecially in carpentrie and cart-wrights worke, as about Elis and Lacedæmon. Neither groweth it in all parts of Fraunce, ne yet in any one quarter of Fraunce.

Chap. IX.

What trees they be that carrie barke good for any uſe.

THe paiſants of the countrey and the ruſticall people employ much, the barke alſo of Beeches, Lindens or Tillets, Firres, and Pitch trees: for thereof they make ſundry veſſels, as paniers, baskets, and certain broad and wide hampers for to carrie their corne and grapes in time of harveſt and vintage, yea and otherwhiles they cover their cottages therewith. Moreover, ſpies uſe to write in barkes (when they be freſh and green) intelligences to their captaines; graving and drawing their letters ſo, as that the ſap and juice thereof covereth them. To conclude, the barke of the Beech tree is uſed in certaine religious ceremonies of ſacrifice: but when the tree is ſpoiled of the barke, it ſoone fadeth and dieth.

Chap. X.

Of Shindles: of the Pine tree, the wild Pine, the Firre, Pitch tree, Larch tree, Torch tree, and the Yew.

THe bourds or ſhindles of the wild Oke called Robur, be of all others ſimply the beſt: and next to them, thoſe which are made of other maſt-trees, and eſpecially of the Beech. The ſhindles are moſt eaſily rent or cloven out of all thoſe trees which yeeld Roſin, but ſetting aſide the Pine-wood onely, none of them are laſting. *Cornelius Nepos* writeth, that the houſen in Rome were no otherwiſe covered over head but with ſhindles, untill the warre with K. *Pyrrhus*, to wit, for the ſpace of 470 years after the foundation of the citie. And of a truth, the chiefe quarters of Rome were divided and diſtinctly named by certain woods and groves neare adjoyning. And even at this day there remaineth the quarter of *Iupiter Fagutalis*, where ſometime ſtood a tuft or

grove of Beeches: also the gate Querquetulana, bearing the name of an Oke-tow: likewise the hill Viminalis, from whence they used to fetch windings and bands of osiers: and many other groves, whereof some were set double, and were two of a name. Wee read in the Chronicles, that *Q. Hortensius* Dictator for the time being, (when as the commons arose, and in that mutinie or insurrection forsook the citie and withdrew themselves to the fort Ianiculum) made a law and published it within a certaine grove hard by, called Esculetum, where there grew a number of trees named Esculi, and the said statute ran in this forme, That whatsoever ordinance should be enacted by the same Comminaltie, it should bind all citizens of Rome whomsoever, to observe and keepe.

In those daies the Pine and Firre, and generally all trees that yeeld Pitch, were held for straungers and aliens, because none of them were knowne to grow near unto the citie of Rome: wherof now we will speake, the rather because the beginning and the whole manner of confecting and preserving wines, might be thereby throughly known. First and formost, some of the trees aforesaid in Asia or in the East parts, doe bring forth Pitch. In Europe there be sixe sorts of trees, seeming all of one race, which yeeld the same. Of which, the Pine and the Pinaster carie leaves thin and slender in manner of haires, long also and sharpe pointed at the end. The Pine beareth least Rosin of all others, howbeit otherwise some it hath in the verie fruit thereof, which we call Pine-nuts or apples (whereof we have alreadie written) yet so little it is, that hardly a man would reckon the Pine among those kind of trees that yeeld Rosin. The Pinaster is nothing els but the wild Pine: it groweth wonderfull tall, putting forth armes from the mids of the trunke or bodie upward; whereas the other Pine, brauncheth only in the head: this of the twaine is more plentifull in Rosin, whereof we will speake more anon. These wild Pines grow also upon plains. There be trees upon the coasts of Italie which men call Tibuli, and many think they be the same, although they carie another name: slender they are and shorter, altogither without knots, and little Rosin they have in them or none: but they serve very well for shipwrights to build frigats & brigandins.

The Pitch-tree loveth the mountains and cold grounds: a deadly and mournfull tree it is, for they used in old time to sticke up a braunch thereof at the dores of those houses where a dead corps was, to give knowledge thereof abroad: yea and commonly it grew greene in churchyards and such places where the manner was to burne the bodies of the dead in funerall fires: but now adaies it is planted in courtyards and gardens near our houses, because it may be easily kept with cutting and shredding, it brauncheth so well. This tree putteth forth great abundance of Rosin, with white graines or kernels comming betweene, so like unto Frankincense, that if it be mingled therewith, unneth or hardly a man may discerne the one from the other by the eye. And hereupon it commeth, that druggists and Apothecaries doe sophisticate Frankincense and deceive folke with it. All the sort of these trees are leafed with short, thicke, and hard prickie bristles, in manner of the Cypresse. The Pitch tree beginneth to shoot forth braunches even from the very root almost, and those be but small, bearing out like armes, and sticking one against another in the sides. Semblably do the Fir-trees, which are so much sought for to serve shipping: and yet this tree delighteth in the highest mountains, as if it fled from the sea of purpose, and could not away with it: and surely the forme and manner of growing is all one with the Pitch tree. The wood thereof is principall good timber for beames, and fitteth our turne for many other necessities of this life. Rosin if it be found in the Firre, is thought a fault in the wood, whereas the only commoditie of the Pitch tree, is her Rosin; and yet sometime there frieth and sweateth out a little thereof, in the extreme heat of the sun. The timber of them both is not alike, for that of the Firre is most faire and beautifull; the Pitch tree wood serveth only for cloven lath, or rent shindles, for Coopers to make tubs and barrels, and for some few other thin bourds and painels.

As for the Larch tree, which is the fift kind of those that beare Rosin: like it is to the rest, and loveth to grow in the same places: but the timber is better by ods, for it rotteth not, but will last and endure a long time: the tree will hardly be killed: besides, it is red of color, and carieth an hoter and stronger smell than the other. There issueth forth of the tree as it groweth, good store of liquid Rosin, in colour like to honey, somwhat more clammie, which will never grow to be hard.

A sixt sort there is of these trees, and it is properly called Teda, [*i.* the Torch-tree:] the same yeeldeth more plentie of moisture and liquor than the rest: lower it is of growth than the Pitch-tree, but more liquid and thin: very commendable also to maintain fire at sacrifices, and to burn in torches for to give light. These trees, I meane the male onely, bring forth that strong and stinking

A king roſin, which the Greekes call Syce. Now, if it happen that the Larch tree prove Teda [i. to be Torch-wood] it is a ſigne that it doth putrifie, and is in the way of dying.

The wood of all theſe kinds beforenamed, if it be ſet a fire, maketh an exceeding groſſe and thicke ſmoke, and preſently turneth into a coale, ſpitting and ſparckling a farre off; except that only of the Larch tree, which neither burneth in light flame, nor maketh coale, ne yet conſumeth in the fire no otherwiſe than a very ſtone.

All theſe trees whereof we ſpeake, continue green all the yeare long: and very like they are in leafe, that men otherwiſe of cunning and good experience, have ynough to doe to diſcerne one from the other by it, ſo neare of kin they be, and their race ſo much intermingled. But the Pitch-tree is not ſo tall as the Larch: for the Larch is thicker in bodie, of a thinner and lighter barke,
B more ſhag leaved, and the ſaid leaves fattier, growing thicker, more pliable, & eaſier to wind and bend: whereas the leaves of the Pitch-tree hang thinner, they be of a driet ſubſtance, more ſlender, and ſubject to cold; and in one word, the whole tree is more rough and hideous to ſee to, and withall, full of roſin; the wood alſo reſembleth the Firre, rather than the Larch.

The Larch tree, if it be burnt to the very ſtumpe of the root, will not ſpring againe and put forth new ſhoots: whereas the Pitch tree liveth ſtill for all the fire, and will grow afreſh: the experience whereof was ſeene in the Iſland Lesbos, at what time as the forreſt Pyrrhæum was ſet on fire, and cleane burnt to the ground.

Moreover, every one of theſe kinds differ in the very ſex: for the male of ech kind is ſhorter and harder: the female taller, having fattier leaves, and the ſame ſoft and plain and nothing ſtiffe and
C rugged. The wood of the male, is tough, and when it is wrought, keepeth not a direct graine, but windeth and turneth, ſo that the Carpenter muſt go every way about it both with axe and plain: contrariwiſe, that of the female is more frim and gentle. And commonly the axe or the hatchet will tell the difference of male and female in any tree; for what wood ſoever it be, it will ſoon find and feele the male, for hardly is it able to enter, but either turneth edge or rebounds again: & whether a man hew or cleave withall, it maketh more craſhing and a greater noiſe where it ſetleth and taketh hold; it ſticketh alſo faſter, and with more adoe is plucked forth. Furthermore, the very wood of any male tree, is of a more browne and burnt colour, yea, & the root of a blacker hew.

About the forreſt Ida within the territorie of Troas, there is another diſtinction of trees in the ſame kind: for ſome grow upon the mountaines, others toward the coaſt and the ſea ſide. In Ma-
D cedonie, Arcadia, and about Elis, theſe trees eftſoones change their names: inſomuch, as the Greeke writers are not agreed how to diſtinguiſh their ſeverall ſorts, and to raunge them duly in their kind. For mine owne part, I have ſet them downe diſtinctly according to the judgement of Romane and Latine Authors.

Of all the trees abovenamed, the Firres ſurpaſſe for bigneſſe: and the females are the taller. The timber is more frim and ſoft, more profitable alſo and eaſier to be wrought: the tree it ſelfe rounder, and ſo it brauncheth arch-wiſe: the boughs as they reſemble wings ſtretched out and diſplaied, ſo they ſtand ſo thicke with leaves, that they will beare off a good ſhower, inſomuch, as no raine is able to pierce through. In ſumme, the female Firre is farre more lovely and beautifull every way than the male.

E All the ſort of theſe foreſaid trees, ſave onely the Larch, beare certaine knobs like Catkins or Chats, compoſed (as it were) of many skales wrought one over another, and thoſe hang downe dangling at the braunches. Theſe knobs or clogs of the male Firre, have in the upper end a kernell within: but thoſe of the female have no ſuch thing. Moreover, the Pitch tree as it hath ſuch Catkins leſſe and ſlenderer; ſo all within, from one end to the other, the kernels be paſſing little and blacke withall, like to lice or fleas: which is the reaſon, that the Greekes call it Phthirophoros. The ſaid Catkins of the male Pitch trees are more flat, and nothing ſo round as thoſe of the females, leſſe gummie alſo and not ſo moiſt of the roſin.

To come now to the Yugh, becauſe we would overpaſſe none: it is to ſee to, like the reſt, but
+ that it is not ſo greene; more ſlender alſo and ſmaller, unpleaſant and fearefull to looke upon, as
F a curſed tree, without any liquid ſubſtance at all: and of theſe kind of trees, it alone beareth Berries. The fruit of the male is hurtfull: for the berries in Spaine eſpecially, have in them a deadly poyſon. And found it hath been by experience, that in Fraunce the wine bottles made thereof for wayfaring men and travellers, have poyſoned and killed thoſe that drunke out of them. *Seſtius* ſaith, that the Greekes call it Smilax: and that in Arcadia it is ſo venomous, that whoſoever

take

take either repoſe or repaſt under it, are ſure to die preſently. And hereupon it commeth, that thoſe poyſons wherewith arrow heads be envenomed, after ſome were called in times paſt Taxica, which now wee name Toxica. But to conclude, it is ſeene by good proofe, that if a braſen wedge or ſpike be driven into the very bodie of the tree, it looſeth all the venomous nature, and becommeth harmeleſſe.

Chap. xi.

How to make all kinds of Pitch. The manner how Cedrium is made. Alſo, of thicke pitch, how it is made, and in what ſort Roſin is boiled.

THe liquid Pitch or Tarre throughout all Europe, is boiled out of the Torch tree: and this kind of Pitch ſerveth to calke ſhips withall, and for many other uſes. Now the manner of drawing Tarre out of this tree, is, to cut the wood thereof into peeces, and when they are piled up hollow into an heape, to make a great fire within, as it were under a furnace, being claied without-forth: thus with the heat of the fire it doth frie and ſeeth againe. The firſt liquour that ſweateth and iſſueth forth, runneth cleare as water, in a channell or pipe made for the purpoſe: and this the Syrians call Cedrium: which is of ſuch force and efficacie, that in Ægypt they uſe to embaulme the dead bodies of men and women departed, and keepe them from putrifaction. At the next running it is thicker, and this ſecond liquor is very Pitch. Howbeit, this is caſt again into certain coppers or cauldrons of braſſe, and together with vinegre ſodden a ſecond time, untill it come to a thicke *conſiſtence: and when it is thus thickened, it taketh the name of Brutian Pitch, good onely for tuns, barrels, and other ſuch veſſels. Much like it is to the former Pitch, but that it is more glutinous and clammie, redder alſo of colour, and more fattie. And thus much concerning the Pitch made of the Torch-tree.

*Palimpaſſa, i. Stone-pitch.

As for that which commeth of the Pitch tree, the Roſin thereof is drawn with red hot ſtones in certain veſſels made of ſtrong and thicke Oken plankes: or, in default thereof the wood is cloven into peeces, and piled together, after the order of a charcole hearth, and ſo the pitch boileth foorth. The uſe hereof, when it is beaten into a kind of meale or powder, is to bee put into wine, and it is of a blacker colour than the reſt. The ſame pitch-roſin, if it be boiled more lightly with water, & be let to run through a ſtrainer, commeth to a reddiſh colour, and is glewie: and thereupon it is called Stilled pitch. And for this purpoſe lightly, is ſet by the more groſſe & faultie ſubſtance of the roſin, together with the barke of the tree. But there is another compoſition and manner of making pitch that ſerveth for headie wine, called Crapula. For the flower of the roſin is taken greene and freſh, as it diſtilleth from the tree, together with a good quantitie of ſmall, thinne, and ſhort ſpils or chips of the tree plucked away with the ſame: the ſame are ſhred and minced ſo ſmall, as they may paſſe through a ſieve or a riddle: which done, all is put into ſcalding water, and there boileth untill it be incorporate with the water. The fat ſubſtance that is ſtrained and preſſed from hence, is the excellent pitch-roſin, hard to come by, and not to bee found in Italie, unleſſe it bee in few places under the Alpes; and ſingular good it is in Phyſicke. Now for to make it paſſing white, there muſt bee taken one gallon of the roſin, and ſodden in two gallons of raine water. But ſome thinke it the better way, to ſeeth it a whole day together at a ſoft fire, without any matter at all, in a pan or veſſell of latton. Others there be likewiſe that boile Terpentine in a hote frying pan, and are of opinion, that this is the beſt of all others. And the next to it in goodneſſe, is the Lentiske roſin, called Maſtich.

Chap. xii.

Of the Pitch Zopiſſa, which is ſcraped from ſhips, and of Sapium. Alſo, what trees are in requeſt for their timber.

IT would not bee forgotten, that the Greekes have a certaine Pitch, ſcraped together with waxe from ſhips that have lien at ſea, which they call Zopiſſa (ſo curious are men to make experiments and trie concluſions in every thing:) and this is thought to bee much more effectuall for all matters that pitch and roſin are good for, by reaſon of the faſt temperature that it hath gotten by the ſalt water.

For

For to draw roſin out of the *Pitch-tree, it muſt be opened on the Sun ſide, not by giving a ſlit or gaſh in the barke, but by cutting out a peece therof, ſo that the tree may gape and lie bare two foot at the moſt: and from the earth, this wound to bee at leaſt a cubite. Neither doe they ſpare the entire bodie and wood of the tree, as they doe in the reſt: for there is no daunger thereof, conſidering that the very chips of the wood being cut out, are full of liquor, and doe ſerve to make pitch. But the nearer that the ſaid ouverture or hole is made to the earth, the better is the roſin that iſſueth forth: for if it be higher, it is bitter. When this is done, all the humour afterwards runneth to the ulcer or inciſion aforeſaid, from every part of the tree. The like it doth in the Torch pine. When it hath left running to the firſt hole, there is a ſecond likewiſe made on another ſide, and ſo ſtill is the tree opened every way: untill at length tree and all is hewed down, and the very pith and marrow thereof ſerveth for Torch wood to burne. Semblably, in Syria they uſe to plucke the barke from the Terebinth, yea, and they pill the boughs and roots too for Terpentine, howſoever in other trees the roſin iſſuing out of thoſe parts, is not counted good. In Macedonie the manner is to burne the male Larch, but the roots onely of the female for to draw out pitch. *Theopompus* wrate, that there is found in the territorie of the Apolloniates, a kind of minerall pitch, called Piſcaſphaltum, nothing inferiour in goodneſſe to the Macedonian. *πίτυς.

The beſt pitch in all countries, is that which is gathered from trees, ſtanding upon the North wind, and in places expoſed to the Sunne-ſhine. As for that which commeth from ſhadowie places, it is more unpleaſant to the eie, and carieth beſides a ſtrong and ſtinking ſavour. If it be a cold and hard winter, the pitch then made is the worſe, there is alſo leſſe ſtore of it, and nothing is it ſo well coloured. Some are of opinion, That the pitch iſſueth in more abundance out of trees in the mountaines, alſo that it is better coloured, ſweeter in taſt, more pleaſant alſo in ſmell, namely, while it is raw pitch-roſin, and as it runneth from the tree: but if it be boiled, it yeeldeth leſſe plentie of pitch than that which commeth of trees in the plaine, and runneth all into a thin liquor in manner of whey, yea, & the very trees themſelves are ſmaller. But both the one and the other, as well the mountaine pines and pitch-trees, as thoſe of the plaines, yeeld not ſo much pitch in a faire and drie ſeaſon, as when the weather is rainie and full of clouds. Moreover, ſome there be of theſe trees that yeeld forth fruit (which is their roſin) the very ſame yeare that immediately followeth their inciſion; others, two yeares after; yea, and ſome again in the third yeare. As for the inciſion or open wound that is made, it filleth up with roſin: for neither dooth it ſouder or unite in manner of a skar, ne yet cloſeth the barke againe: for in this tree, being once devided it will never come together and meet.

Among theſe trees, ſome have reckoned one kind by it ſelfe named Sapium, becauſe it is replanted and groweth of ſome of the ſions or imps of the ſaid trees, in manner as hath been ſhewed before in our treatiſe of nut-kernels. The nether parts of which tree they call Tedaſi. Torch-wood:] whereas indeed this tree is no other than the Pitch-tree, brought to a more mild and gentle nature by tranſplanting. As for that which the Latines call Sapinus, it is nothing elſe but the wood or timber of theſe kind of trees, being hewed or cut downe, as we will *hereafter declare in place convenient. *Chap. 39 of this booke.

Chap. xiii.

Of the Aſh, foure kinds thereof.

THere be many trees beſides that Nature hath brought forth, onely for their wood and timber: and among them the Aſh, which of all others, groweth moſt plenteouſly in every place. A tall tree this is, and groweth round, bearing leaves ſet in manner of feathers or wings; much ennobled by the praiſe and commendation that the Poet *Homer* giveth it, as alſo for the ſpeare or launce of *Achilles*, made thereof. And in very truth, the wood ſerveth right well for many uſes. As for the timber of the Aſh, growing upon the forreſt Ida in Troas, it is ſo like the Citron-wood, that when the bark is off, a man may hardly diſcern the one from the other, inſomuch, as the merchants and chapmen are deceived therewith.

The Greekes have made two kinds of the Aſh: the one runneth up tall and even without a knot: the other is lower, more tough and hard, and withall, of a more brown and duskiſh colour: and the leaves reſemble the Lawrell. In Macedonie they have an Aſh, which they call Bumelia, which of all other is the talleſt and biggeſt, the wood wherof is moſt pliable and bending. Others have

have put a difference betweene Ashes, according to the places: for that of the plaine and champion countrey, hath a more curled or frisled graine than the other of the mountaines, but contrariwise, the wood of this is more compact and harder than the other. The leaves of this tree, according to the Greekes, are hurtfull, venomous, and deadly to Horses, Mules, and such labouring garrons; but otherwise to beasts that chew cud, they be harmelesse. Howbeit, in Italie, if horses, &c. doe brouse of the leaves, they take no harme thereby. Moreover, they be excellent good, and nothing so soveraigne can be found against the poyson of serpents, if the juice thereof bee pressed forth, & given to drinke; or to cure old ulcers, if they be applied and laid thereto in manner of a cataplaster: nay, so forcible is their vertue, that a serpent dare not come neare the shaddow of that tree, either morning or evening, notwithstanding at those times it reacheth farthest; you may be sure then they will not approch the tree it selfe, by a great way. And this am I able to deliver by the experience which I have seene, that if a man doe make a round circle with the leaves thereof, and environ therewith a serpent and fire together within, the serpent will chuse rather to goe into the fire, than to flie from it to the leaves of the ash. A wonderfull goodnesse of dame Nature, that the Ash doth bloome and flourish alwaies before that serpents come abroad; and never sheddeth leaves, but continueth green, untill they be retired into their holes, and hidden within the ground.

Chap. XIIII.

Of the Line or Linden tree, two sorts thereof.

GReat difference there is every way between the male and female Linden tree; for, the wood of the male is hard and knottie, of a redder colour also, and more odoriferous than the female. The barke moreover is thicker, and when it is plucked from the tree, it is stiffe, and will not bend. It beareth neither seed nor flower, as the female doth: which also is rounder and bigger in bodie, and the wood is whiter and more faire and beautifull by farre than is the male. A strange thing it is to consider, that there is no living creature in the world will touch the fruit of the Linden tree, and yet the juice both of leafe and barke is sweet ynough. Between the barke and the wood of this tree there bee thin pellicles or skins lying in many folds together, whereof are made bands and cords called Bazen ropes. The finest of these pellicles or membranes served in old time for to make the labels and ribbands belonging to chaplets, and it was reputed a great honour to weare such. The timber of the Linden or Tillet tree will never be worme-eaten.* The tree it selfe is nothing tall, but of a meane height, howbeit the wood is very commodious.

* *Plinie* herein is deceived. For the Line-tree with us, is cõparable to the highest Okes in talnesse.

Chap. XV.

Ten kinds of the Maple tree.

THe Maple in bignesse is much about the Linden tree: the wood of it is very fine and beautifull, in which regard, it may bee raunged in the second place, and next to the very Citron tree. Of Maples there bee many kinds: to wit, the white, and that is exceeding faire and bright indeed, growing about Piemont in Italie, beyond the river Po, and also beyond the Alps, and this is called the French Maple. A second kind there is, which hath a curled graine running to and fro with diverse spots; the more excellent worke whereof, resembling the eies in the Peacockes taile, thereupon tooke also the name. And for this rare and singular wood, the countries of Istria and Rhætia bee cheefe. As for that which hath a thicke and great graine, it is called Crassivenium of the Latines, and is counted to bee of a baser kind. The Greekes distinguish Maples by the diverse places where they grow. For that of the champion or plaine countrey (which they name Glinon) is white, and nothing crisped: contrariwise, the wood of the mountaine Maple is harder and more curled, and namely, the male of that sort, and therefore it is in great request for most exquisite and sumptuous workes. A third sort they name Zygia, which hath a reddish wood, and the same easie to cleave: with a barke of a swert colour, and rough in handling. Others would have it to be no Maple, but rather a tree by it selfe, and in Latine they call it Carpinus.

Chap.

Chap. xvi.

Of the Bosses, Wennes, and Nodosities, called Bruscum and Molluscum: Of the wild Fistick or Bladder nut-tree called Staphylodendron: also, three kinds of the Box-tree.

THe bunch or knurre in the Maple, called Bruscum, is passing faire, but yet that which is named Molluscum, excelleth it. Both the one and the other swell like a wen out of the Maple. As for the Bruscum, it is curled & twined after a more crawling and winding manner: whereas the Molluscum is spread with a more direct and streight course of the graine. And certes, if there might be plankes hereof found, broad ynough to make tables, doubtlesse they would be esteemed and preferred before those of the Citron-wood. But now it serveth only for writing tables, for painels also and thin bords in wainescot work, to set out beds heads and seelings, and such are seldome seene. As for Bruscum, there bee tables made of it, inclining to a blackish colour. Moreover, there be found in Alder trees, such nodosities; but not so good as those, by how much the wood of the Alder it selfe is inferiour to the Maple, for beautie and costlinesse. The male-Maples doe put forth leaves and flourish before the female. Yea, and those which grow upon drie grounds, are ordinarily better esteemed than those of moist and wateriſh places, in like sort as the Ashes.

Beyond the Alpes there is a kind of Bladder nut-tree, whereof the wood is very like unto the white Maple, and the name of it is Staphylodendron. It beareth certaine cods, and within the same, kernels in tast like the Filberd or Hazell-nut.

Now for the Box-tree, the wood thereof is in as great request as the very best: seldome hath it any graine crisped damaske wise, and never but about the root, the which is dudgin and full of worke. For otherwise the grain runneth streight and even without any waving: the wood is sad ynough and weightie: for the hardnesse thereof, and pale yellow colour, much set by and right commendable. As for the tree it selfe, gardeners use to make arbours, borders, and curious works thereof. Three sorts there be of the Box-tree: the first is called the French boxe, it groweth taperwise, sharpe and pointed in the top, and runneth up to a more than ordinarie height. The second is altogether wild, and they name it Oleastrum, good for no use at all; and besides carieth a strong and stinking savor with it. The third is our Italian Boxe, and so called. Of a savage kind I take this to be also: howbeit, by setting and replanting, brought to a gentle nature. This spreadeth and brancheth more broad: and herewith a man shall see the borders and partitions of quarters in a garden, growing thicke and greene all the year long, and kept orderly with cutting and clipping. Great store of Box-trees are to be seene upon the Pyrenæan hils, the Cytorian mountaines, and the whole Berecynthian tract. The thickest and biggest Box-trees be in Corsica, and they beare a lovely and amiable flower, which is the cause, that the honie of that Island is so bitter. There is not a beast that will eat the fruit or graine thereof. The Boxes of Olympus in Macedonie, are more slender than the rest, and but low of growth. This tree loveth cold grounds, yet lying upon the Sunne. The wood is as hard to burne as yron: it will neither flame or burne cleare it selfe, nor serve to make charcole of.

Chap. xvii.

Of the Elme, foure kinds.

BEtween these wild trees abovesaid, and those that beare fruit, the Elme is reckoned of a middle nature, in regard of the wood and timber that it dooth affoord, as also of the friendship and acquaintance that it hath with Vines. The Greekes acknowledge two sorts thereof: namely, the one of the mountaines, which is the taller and bigger: and the other of the plaines and champion; which is the rather more like a shrub, the branches that it shooteth foorth are so small and slender. In Italie men hold the Elmes about Atinum to bee the tallest, and of those they preferre them which grow in drie grounds, and have no water comming to them, before those by river sides. A second sort of them, which are not all out so great, they call the French Elmes. The third kind be Italian Elmes, thicker growne with leaves than the rest, and those proceeding in greater number from one stemme. In the fourth place bee raunged the wild Elmes.

The

The Atinian Elmes aboveſaid beare no Samara (for ſo they call the ſeed or graine of the Elme.) All the kind of them are planted of ſets taken from the roots, whereas others come of ſeeds.

Chap. xviii.

The nature of trees, as touching the place where they grow.

HAving thus diſcourſed in particular of the moſt famous and noble trees that are. I thinke it not amiſſe to ſay ſomewhat of their natures in generall. And firſt to begin with the mountain high countries: the Cedar, the Larch, and the Torch-tree love to grow among the hils; like as all the reſt that engender roſin: ſemblably, the Holly, the Boxe-tree, the Maſt-holme, the Iuniper, the Terebinth, the Poplar, the wild Aſh Ornus, the Cornell tree, and the Carpin. Vpon the great hill Apennine there is a ſhrub named Cotinus, with a red or purple wood, moſt excellent for inlaid workes in Marquettrie. As for Firres, the wild hard Okes (Robora) Cheſtnut-trees, Lindens, Maſt-holmes, and Cornell trees, they can away with hils and valleies indifferently. The Maple, the Aſh, the Servis tree, the Linden and the Cherry-tree, delight in the mountaines neare to waters. Lightly a man ſhall not ſee upon any hill, Plum-trees, Pomgranate trees, wild Olives, Walnut-trees, Mulberrie trees, and Elders. And yet the Cornell tree, the Hazell, the common Oke, the wild Aſh, the Maple, the ordinarie Aſh, the Beech, and the Carpin, are many times found to come downe into the plaines: like as the Elme, the Apple tree, the Peare tree, the Bay tree, the Myrtle, the Bloud ſhrubs, the Holme, and the Broome (which naturally is ſo good for to die clothes) doe as often climbe up the mountaines. The Servis tree gladly groweth in cold places: ſo doth the Birch, and more willingly of the twaine. This is a tree which is meere French, and came firſt out of Fraunce: it ſheweth wonderfull white, and hath as fine and ſmall branches or twigs, which are ſo terrible to the offenders, as wherewith the Magiſtrats rods are made for to execute juſtice. And yet the wood of this tree is paſſing good for hoopes, ſo pliable it is & eaſie to bend: the twigs thereof ſerve alſo for to make paniers and baskets. In France they uſe to boile the wood, and thereof draw a glutinous and clammie ſlime in manner of Bitumen. In the ſame quarters there loveth to grow for companie the white thorn, which in old time they were wont to burne for torches at weddings, and it was thought to be the moſt fortunat and luckie light that could be deviſed, becauſe (as *Maſſurius* doth report) the Romane ſheepheards and heardmen who raviſhed the Sabine maidens, were furniſhed every one with a branch thereof, to make them torches. But now adaies the Carpine and the Hazell are commonly uſed for ſuch nuptiall lights. The Cypreſſe, Walnut, Cheſtnut-trees, and the Laburnum cannot in any wiſe abide waters. This laſt named, is a tree proper unto the Alpes, not commonly knowne: the wood thereof is hard and white: it beareth a bloſſome of a cubite long, but Bees will not ſettle upon it. The plant likewiſe called Iovis Barba, ſo handſome to bee cut in arbours and garden workes, which groweth ſo thicke and round withall, full of leaves, and thoſe of a ſilver colour, hateth waterie places. Contrariwiſe, Willowes, Alders, Poplars, & Oiſiars, and the Privet which is ſo good for to make dice, will not grow well and proſper but in moiſt grounds. Alſo the Vacinia or Whortles, ſet and ſowed in Italie for the fowlers to catch birds withall; but in France for the purple colour, wherewith they uſe to die cloths for their ſervants and ſlaves.

To conclude, this is a generall rule, What trees ſoever will grow indifferently as well upon hils as plaines, ariſe to be taller, bigger, & carie a fairer head to ſee to in the low champion grounds: but timber is better, and carieth a more beautifull graine upon the mountaines, except onely Apple-trees and Pyrries.

Chap. xix.

A diviſion of trees, according to their generall kinds.

MOreover, ſome trees looſe their leaves: others continue alwaies greene. And yet there is another difference of trees before this, and wherupon this dependeth. For trees there be which are altogether wild & ſavage: there be again which are more gentle and civile: and theſe names me thinks are very apt to diſtinguiſh them. Thoſe trees therfore which are ſo kind and familiar unto us, as to ſerve our turns either with their fruit which they bear, or their ſhade which they yeeld, or any other vertue or propertie that they have, may very aptly and fitly be called civile and domeſticall.

Chap.

Chap. xx.

Of trees that never shed their leaves: also of Rhododendron.

AMong these trees and plants which are of the gentle kind, the Olive, the Lawrell, the Date tree, Myrtle, Cypresse, Pines, Ivie, and the Oleander, loose not their leaves. As for the Oleander, although it bee called the Sabine hearb, yet it commeth from the Greekes, as may appeare by the name Rhododendron. Some have called it Nerion, others Rhododaphne: it continueth alwaies green leafed, beareth flowers like roses, and brauncheth very thicke. Hurtfull it is and no better than poison, to Horses, Asses, Mules, Goats, and Sheep, and yet unto man it serveth for a countrepoison, and cureth the venime of serpents.

Chap. xxi.

What trees shed not their leaves at all: which they be that loose them but in part: and in what countries all trees are ever greene.

OF the wild sort, the Firre, the Larch, the wild Pine, the Iuniper, the Gedar, the Terebinth, the Box tree, the mast-Holme, the Holly, the Corke tree, the Yew, and the Tamariske, be greene all the yeare long. Of a middle nature betweene these two kinds abovenamed, are the Adrachne in Greece, and the Arbut or Strawberrie tree in all countries: for these loose the leaves of their water-boughs, but are ever green in the head. Among the shrubs kind also, there is a certaine bramble and Cane or Reed, which is never without leaves. In the territorie of Thurium in Calabria, where sometime stood the city Sybaris, within the prospect from the said cittie, there was one Oke above the rest to be seene, alwaies green and full of leaves, and never began to bud new before midsummer: where by the way, I marveile not a little, that the Greeke writers delivered thus much of that tree in writing, and our countrymen afterwards have not written a word thereof. But true it is, that great power there is in the climat: insomuch as about Memphis in Ægypt, and Elephantine in the territorie Thebais, there is not a tree (not so much as the verie vine) that sheddeth leaves.

Chap. xxii.

The nature of such leaves as fall from trees: and what leaves they be that chaunge colour.

ALl trees without the raunge of those before rehearsed (for to reckon them up by name particularly were a long and tedious peece of worke) doe loose their leaves in winter. And verily this hath been found and observed by experience, that no leaves do fade & wither, but such as be thin, broad, & soft. As for such as fall not from the tree, they be commonly thicke skinned, hard, and narrow: and therefore this is a false principle and position which some hold, That no trees doe shed their leaves which have in them a fattie sap or oleous humiditie: for who could ever perceive any such thing in the mast-Holme? a drier tree there is not, and yet it holdeth alwaies green. *Timæus* (the great Astrologer and Mathematician) is of opinion, that when the sunne is in the signe Scorpio, he causeth leaves to fall, by a certain venomous and poisoned infection of the aire, proceeding from the influence of that maligne constellation. But if that were true, we may well and justly marveile, why the same cause should not be effectuall likewise in all other trees. Moreover, we see that most trees doe let fall their leaves in Autumne: & some are longer ere they shed, and continue greene untill winter bee come. Neither is the timely or slow fall of the leafe long of the early or late budding; for wee see some that burgen and shoot out their spring with the first, and yet with the last shed their leaves and become naked: as namely the Almond trees, Ashes, and Elders. And contrariwise, the Mulberrie tree putteth foorth leaves with the latest, and is one of them that soonest sheddeth them againe. But the cause hereof lyeth much in the nature of the soile: for the trees that grow upon a leane, drie, and hungrie ground, doe sooner cast leafe than others: also old trees become bare before younger: and many of them also loose their leaves ere that their fruit be fully ripe: for in the Fig-tree, that commeth and beareth late, in the winter Pyrrie, and Pomegranate, a man shall see in the latter end

of the yeare, fruit only and no leaves upon the tree. Now as touching those trees that continue ever greene, you must not thinke that they keepe still the same leaves, for as new come, the old wither and fall away: which happeneth commonly in mid-Iune about the summer Sun-stead. For the most part, the leaves in every kind of tree, doe hold one and the same colour, and continue uniforme, save those of the Poplar, Ivie, and Croton, which wee said was called also Cici, [i. Ricinus, or Palma Christi.]

Chap. xxiii.

Three sorts of Poplar: and what leaves they be that chaunge their shape and figure.

OF Poplars, there be found three sundrie kinds, to wit, the white, the black, and that which is named * Lybica, or the Poplar of Guynee: this hath least leaves, and those of all other blackest; but most commendable they are for the frugous meazles (as it were) that come forth thereof. As for the white Poplar leafe, it is of two colours; the upper side is whitish, the nether part greene. Both of it, and of the black Poplar, the leaves when they be young, are as round as if they were drawne with a paire of compasses, like unto those of Croton before-named: but as they grow elder, they run out into certaine angles or corners. Contrariwise, the Ivie leaves, at the first be cornered, and afterwards become round. All Poplar leaves are full of downe: as for the white Poplar (which is fuller of leaves than the rest) the said down flieth away in the aire, like to mossie chats or thistle-downe. The leaves of Pomegranats and Almond trees stand much upon the red colour. But very straunge it is and wonderfull which happeneth to the Elme, Tillet or Linden, the Olive tree, Aspe, and Sallow or Willow: for their leaves after midsummer, turne about upside downe, in such sort, as there is not a more certaine argument that the sunne is entred Cancer, and returneth from the South point or summer Tropicke, than to see those leaves so turned.

* Taken by some, to be our Aspe.

Chap. xxiiii.

What leaves they be that use to turne every yeere. Of Palme or Date tree leaves, how they are to be ordered and used. Also certaine wonderfull observations about leaves.

THere is a certain generall and universall diversitie and difference observed in the very leafe: for commonly the upper side which is from the ground, is of greene grasse colour, more smooth also and polished. The outside or nether part of the leafe, hath in it certain strings, sinewes or veines, brawnes and joynts, bearing out like as in the backe-part of a mans hand: but the inside, cuts or lines, in manner of the palme of ones hand. The leaves of the Olive, are on the upper part whiter, and lesse smooth; and likewise of the Ivie. But the leaves of all trees for the most part, every day doe turne and lie open to the Sunne, as desirous to have the inner side warmed therewith. The outward or nether side toward the ground of all leaves, hath a certaine hoarie downe more or lesse here in Italy, but in other countries so much there is of it, that it serveth the turne for wooll and cotton. In the East parts of the world, they make good cordage and strong ropes of Date tree leaves (as we have said before;) and the same are better, and serve longer within, than without. With us these Date leaves are pulled from the tree in the spring, whiles they be whole and entire; for the better are they which are not cloven or divided. Beeing thus plucked, they are laid a drying within-house foure daies togither: after that, they be spred abroad and displaied open to the sunne, and left without dores to take all weathers both day and night, and to bee bleached, untill they be drie and white: which done, they be slived and slit for cord-worke. But to come againe unto other leaves, the broadest are upon the Figge-tree, the Vine, and the Plane; the narrowest, upon the Myrtle, Pomegranat, and Olive: as for those of the Pine and Cedar, they be hairie. The Holly leaves, and all the kinds of Holme, are set with sharpe pricks. As for the Iuniper, in stead of leafe it hath a very pointed thorne. The Cypresse and Tamariske carrie fleshie leaves: those of the Alder be most thicke of all other. The Reed and the Willow have long leaves: the Date tree hath them double. The leaves of the Peare tree are round, but of the Apple tree pointed; of the Ivie cornered; of the Plane tree divided into certain incisions; of the Pitch tree and the Firre cut in, after the manner of comb-teeth; of the wild

hard

A hard Oke, waved and indented round about the edges; of the brier and bramble, ſharpe like thornes all the skin over. Of ſome, they be ſtinging and biting, as of Nettles: of others, readie to pricke like pins or needles, as of the Pine, the Pitch tree, the Larch, the Firre, the Cedar, and all the ſorts of Holly. The leaves of the Olive tree, and the maſt-Holme, hang by a ſhort ſtele, the Vine leaves by a long. The Poplar or Aſpen leaves doe ſhake and tremble, and they alone keepe a whiſtling and ruſtling noiſe one with another. Moreover, in the very fruit it ſelfe, and namely in a certaine kind of Apples, ye ſhall have ſmall leaves breake out of the very ſides in the mids, in ſome ſingle, in others double and two togither. Furthermore, there bee trees that have their leaves comming forth about their boughs and branches, others at the very end and ſhoot of the twig: as for the wild oke Robur, it putteth leaves forth of the trunke and maine ſtocke. Over and
B beſides, the leaves grow thicker or thinner in ſome than in others; but alwaies the broad and large leaves, are more thin than others. In the Myrtle tree, the leaves grow in order by rankes; thoſe of the Box tree turne hollow; but in the Apple trees they are ſet in no order at all. In Pyries and Apple trees both, yee ſhall ſee ordinarily many leaves put forth at one bud, hanging at one and the ſame taile. The Elme, and the Tree-trifolie, are full of ſmall and little braunches. *Cato* addeth moreover and ſaith, That ſuch as fall from the Poplar or the Oke, may bee given as fodder to beaſts, but he willeth that they be not over drie: and he ſaith expreſſely, that for kine and oxen, Fig leaves, maſt-Holme leaves, and Ivie, are good fodder: yea and ſuch kind of beaſts may well brouſe and feed of Reed leaves and Bay leaves. Finally, the Serviſe tree looſeth her leaves all at once, others ſhed them by little and little one after another. And thus much for the leaves
C of trees.

Chap. xxv.

The order and courſe obſerved in Nature as touching plants and trees, in their conception, flowring, budding, knotting, and fructifying. Alſo in what order they put forth their bloſſoms.

THe manner and order of Nature yeare by yeare, holdeth in this wiſe: firſt, trees and plants doe conceive by the means of the Weſterne wind Favonius, which commonly beginneth to blow about ſixe daies before the Ides of Februarie: for this wind is in ſtead of an huſ-
D band to all things that grow out of the earth, and of it they deſire naturally to be conceived, like as the Mares in Spaine, of which we have written heretofore. This wind is that ſpirit of generation which doth breath life into all the world; which the Latines call thereupon Favonius, *à favendo*, [*i.* of cheriſhing and nouriſhing every thing] as ſome have thought. It bloweth directly from the Æquinoctiall Sun-ſetting, and evermore beginneth the Spring. This time, our ruſticall peaſants call the Seaſoning, when as Nature ſeemeth to goe proud or aſſaut, and is in the rut and furious rage of love, deſirous to conceive by this wind, which indeed doth vivifie and quicken all plants and ſeeds ſowne in the ground. Now all of them conceive not at once, but in ſundrie daies: for ſome are preſently ſped in a moment, like as living creatures: others are not ſo haſtie to conceive, but long it is firſt ere they retaine, and as long againe before their vitall ſeed
E doth put forth; and this is thereupon called their budding time. Now are they ſaid to bring forth and be delivered, when in the Spring they bloome, and that bloſſome breaketh foorth of certaine matrices or ventricles. After this, they become nources all the while they cheriſh & bring up the fruit: and this time alſo the Latins call Germinatio, [*i.* the breeding ſeaſon.] When trees are full of bloſſomes, it is a ſigne that the Spring is at the heigth, and the yeare become new againe. The bloſſome, is the very joy of trees, and therein ſtandeth their chiefe felicitie: then they ſhew themſelves freſh and new, as if they were not the ſame; then be they in their gay coats; then it ſeemeth they ſtrive avie one with another in varietie of colours, which of them ſhould excell and exceed in beautifull hew. But this is not generall, for many of them are denied this pleaſure, and enjoy not this delight; for all trees bloſſome not: ſome are of an heavie and ſad
F countenance, neither cheare they at the comming of this new ſeaſon and gladſome Spring: for the maſt-Holme, the Pitch tree, the Larch, and the Pine, doe not bloome at all, they are not arrayed in their robes, they have not their liveries of divers colours to fore-ſignifie (as meſſengers and vantcourriers) the arrivall of the new yeare, or to welcome and ſolemnize the birth of new fruits. The Figge trees likewiſe both tame and wild, make no ſhew of flowers: for they are

not to soone bloomed (if they bloome at all) but they bring forth their fruit. And a wonderfull thing it is to see what abortive fruit these Figge-trees have, and how it never commeth to ripenesse. Neither doe the Iunipers bloome at all. And yet some writers there be who make two kinds thereof: and they say, that the one doth flower, and beare no fruit: as for the other which doth not blossome, it brings forth fruit upon fruit, and berie upon berie, which hang two yeers upon the tree before they come to maturitie. But this is false, for in verie truth all Iunipers without exception, have evermore a sad looke, and at no time shew merie. And this is the case and condition verily of many a man, whose fortune is never in the flower nor maketh any outward shew to the world. Howbeit there is not a tree but it buddeth, even those that never blossome: And herein the diversitie of the soile is of great power: for in one and the same kind, such as grow in marish grounds, do shoot and spring first; next to them, those of the plains; and last of all they of the woods & forrests. And generally the wild Pyrries growing in woods do bud later than any other. At the first comming of the westerne wind Favonius, the Corneill tree doth bud; next to it, the Bay; and somwhat before mid-march or the spring Æquinoctiall, the Tillet or Linden, and the Maple. The Poplar, Elme, Willow, Alder, and Filberds or Hazell nut trees, bud with the first. The Palme also maketh hast and is loth to come behind. All the rest at the point and prime of the spring, namely the Holly, the Terebinth, the Paliurus, the Cheston, and the Walnut-trees, or Mast-trees. Appletrees are late ere they bud, but the Corke tree longest of any other. Trees there be that put forth bud upon bud, by reason that either the soile is exceeding battill and fat, or else the weather fair and pleasant: and this hapneth more to be seen in the blades of corne. But trees if they happen to be over ranck in new shoots and buds, they wax wearie and grow out of heart.

Ex Theophrast. διὸς βλάστ.

Moreover, some trees there be that naturally doe sprout at other seasons besides the spring, according to the influence of certaine starres, whereof the reason shall be rendered more convenient, in the third booke next ensuing after this. Meanetime this would bee observed, That the winter spring of trees is about the rising of the Ægle-star: the Summer budding at the rising of the Dog-star: and a third, when the star Arcturus is up. And for the latter twaine, some would have them to be common verily to all trees, but most evidently seen, in Fig-trees, Vines, Pomgranate trees: and they yeeld a cause, For that in Thessalie and Macedonie the Fig tree about these times putteth forth most plenteously: & in Ægypt this reason is to be seen most apparantly. As for all other trees, certain it is, that when they begin once to bud, they hold on and shoot forward continually without intermission. The wild Oke, the Fir, and the Larch tree, have their severall shoots in one yeere, and spring at three sundry times, giving over betweene whiles; and therefore they put forth their sprouts between the skales of their barks: a thing usually hapning to all trees in their budding & breeding time; for after they be once conceived, their rind or bark doth burst withall. Now their first budding is in the prime and beginning of the spring, and continueth much about fifteene dayes. They bud a second time in the moneth of May when the sun passeth through the sign Gemini: by which time it is evidently to be seen, how the bud heads that came first, are driven and thrust up higher by those that follow after; and that appeareth more plainly by the encrease of the knots and joynts. As for the third budding, it is very short, namely at * midsommer, and lasteth not above a seven-night: and even then also may a man perceive manifestly by the knots and joynts of the shoots how much they are put forth and grown. The Vine alone shooteth twice, to wit, when she first beginneth to burgen and put forth a grape; and a second time, when she doth forme and digest or concoct the same. As for those trees that blossome not, they have no more to do but only to bring forth their fruit, and so proceed to ripen it. Now there are some trees, which no sooner bud, but they shew also a blossome; and yet as hasty as they be that way, they take their leisure afterwards, and long it is ere their fruit come to be ripe: and such are the Vines. Others againe bee as backward and slow both to bud and blossome; but they make speed to ripen their fruit, as the Mulberie tree, which of civile and domesticall trees, is the last that doth bud, and never before all the cold weather is past; and therefore she is called the wisest tree of all others: but after that she begins once to put forth buds, she dispatcheth her busines out of hand, insomuch as in one night she hath done; and that with such a force, that in the breaking forth a man may evidently heare a noise. Of those trees which do conceive in winter, about the rising of the Ægle-star, (as we have sayd before) the Almond tree is the first that doth blossome in the moneth of Ianuarie, and by March the Almond is ripe. The next that blossome

* *Solstitium.*

A bloſſome after it, be the Peach-plum trees of Armenia, then the Injube trees called Tuberes, and the Abricots. As touching thoſe former, they be meere ſtraungers, but theſe Abricots are forced by Art and induſtrie of man. As for wild and ſavage trees, by courſe of nature the Elder flowreth firſt, and hath of all other moſt plentie of pith or marow within, wheras the male Corneil hath none at all. But of domeſticall and civile trees, the Apple tree beginneth to bloſſome, and ſoone after the Pyrry, Chertie tree, and Plum tree, inſomuch as they ſeeme all to floure togither. Next to them, is the Lawrell; anon after it, the Cypreſſe; and then the Pomegranat, and the Fig tree: Vines and Olive trees doe but then burgen and bud, when thoſe other be in their flowre: for in truth they conceive late, namely, at the riſing of the Vergiliæ or Broodhen; for this is the proper ſtar to the influence whereof theſe trees be ſubject: and it is Iune firſt and the ſummer Sun-ſtead, before the vine doth bloome; and ſo it is with the Olive tree, but that it commeth ſomewhat later. All trees be ſeven daies at the leaſt in their bloſſoming; and ſome are longer ere they give over, but none paſſe a fortnight: and done they have ever by the eigth day before the Ides of Iuly, which are the fore-runners of the Eteſian winds. Finally, ſome trees there are which doe not knit or ſhew their fruit immediatly upon their blooming.

B

Chap. xxvi.

Of the Corneil tree. Alſo, what is the proper time wherein every tree beareth: which trees be they that beare not, and which be reputed unluckie. Alſo of thoſe trees which ſooneſt looſe their fruit. Laſt of all, what trees ſhew fruit before leafe.

C

AS for the Corneil tree, it is about midſummer or the ſummer Sun-ſtead, before it putteth forth any fruit, which at firſt is white, afterwards red as bloud. But the female of this kind beareth after Autumne, ſowre berries, and ſuch as no beaſt will abide to taſt. The wood thereof alſo is ſpungeous, hollow, and good for nothing; whereas that of the male is counted among the hardeſt that be: ſo great difference there is in trees of one and the ſame kind. Moreover, the Terebinth, Maple, and Aſh, yeeld their fruit or ſeed in harveſt time: Walnuts, Apples, and Peares (unleſſe they be ſome winter fruits, or of the haſtie kind) ordinarily are readie to bee gathered in the Autumne. All maſt-trees be later ere they render their fruit, to wit, about the go-

D ing downe of the Vergiliæ or beginning of the winter, ſave onely the Æſculus, which paſſeth not the Autumne. As for certain Apple trees and Peare trees both, as alſo the Corke tree, their fruit is not to be gathered before winter begin. The Firre putteth foorth a bloſſome of a yellow colour like Saffron, about mid-Iune or the ſummer ſun-ſtead; but the Broodhen-ſtarre is downe before the fruit be ripe. The Pine, and Pitch tree, do bud before the Firre ſome fifteen daies, or thereabout; but it is winter firſt, and the foreſaid Vergiliæ or Brood-hen is likewiſe ſet, before their fruit is ripe. Citron trees, Iunipers, and maſt-Holmes, are counted trees that beare all the yeare long, and the old fruits of the former yeare tarieth on the tree untill new come, and they hang both togither. But above all other trees, the Pine is a wonder in nature; for a man ſhall ever find upon it ſome of the fruit readie to be ripe; and ſome againe that will remaine unto the

E next yeare, and the third yeare before it will be readie: and there is not another tree that is more forward and greedie (as it were) to put foorth it ſelfe, and give greater hope of encreaſe, than it doth: for look in what moneth ſoever the Pine-nuts are gathered from the tree, in the very ſame others are in good forwardneſſe of ripening; and in ſuch ſort ſhe ordereth the matter, that every moneth a man ſhall have ripe fruit upon her. Thoſe Pine-apples or nuts which cleave and open upon the tree, bee called Zamiæ; and well may they be ſo named, for unleſſe they be plucked, they hurt and corrupt the reſt. The only trees that beare no fruit at all, that is to ſay, not ſo much as ſeed, are theſe; the Tamariske, good for nothing but to make beeſoms of; the Poplar, Alder, Atinian Elme, and the Alaternus, which hath leaves reſembling the Holme, and partly the Olive. As for ſuch trees which neither at any time are ſet or planted, nor yet beare fruit, they bee holden for unfortunate, accurſed, and condemned, in ſuch ſort, as there is no uſe of them in any ſacrifice or religious ſervice. *Cremutius* writeth, That the (Almond) tree whereon ladie *Phyllis* hanged her ſelfe, had never (after) greene leaves on it. Such trees as yeeld gum, after they have put forth their bud, doe cleave and open: howbeit the gum that iſſueth forth, never commeth to any thickneſſe, untill the fruit thereof be gathered. Young trees commonly beare not, ſo long

as they shoot and grow. The Date tree, the Fig tree, the Almond tree, the Apple tree, and the Pyrrie, doe sooneſt of all other let their fruit fall before it be fully ripe. Semblably, the Pomegranate tree, which is so tender besides, that with every thicke and heavie dew, white frost, and foggie rime, she will be bitten and shed the blossom: which is the cause that folk use to bend the boughs thereof downward to the ground, that both dew and rime may sooner fall off which lighteth upon them, and otherwise would over-load and hurt them. The Pyrrie and the Almond tree cannot abide close and cloudie weather, especially if the wind be Southerly, although no raine doe fall: for in such daies, if they chaunce to blossome, they not only shed their flower, but loose their fruit new knit. But the Sallow or Withie tree, is of all other most tickliſh, & sooneſt doth forgoe the seed or chats that it beareth before it commeth to any ripeneſſe: for which cause, called it is of *Homer* * Loose-fruit, or Spill-fruit. Howbeit the age ensuing (naught as it was) hath interpreted that Epithet of his, in another sense, according to the wicked experience they had of it, whereby it was found, that the seed thereof causeth barrainneſſe in women, and hindreth conception. But in this regard, Nature also hath done well to prevent this mischiefe and inconvenience, in that shee hath not been very carefull to preserve the seed: and yet for the maintenance of the whole kind, shee hath endued it with this gift, To grow very quickly, if a man doe pricke into the ground but a cutting or twig thereof. And yet (by report) there is one Willow in Candie, and namely about the very descent of *Iupiters* cave, which is wont ordinarily to carie the graine or seed thereof untill it be full ripe, and then is it of a rough and writhen shape, of a wooden and hard substance, and withall, of the bigneſſe of a cich peaſe.

* Οδυσ. μ. ὀλεσικαρπος, *Frugiperda.*

Moreover, some trees there be that proove barraine and fruitleſſe by occasion of the imperfection of the soile and territorie where they grow: and namely in the Isle Paros, there is a whole wood or coppise that usually is lopt and cut, but it never beareth any fruit. The Peach trees in the Island Rhodos blossome only, and otherwise are fruitleſſe. Over and besides, this difference of trees (that some be fruitfull and others barrain) ariseth of the sex also; for commonly the males beare not: howsoever some affirme cleane contrarie, and say, They are the male onely which be fruitfull, and the female barraine. Furthermore, it falleth out many times that trees be fruitleſſe, either because they grow too thicke one by another, or els are overcharged and too ranke with boughs and braunches: but of such as doo beare, some bring forth their fruit both at the sides, and also at the very tips and ends of their braunches; as the Peare tree, Pomegranat tree, Figge tree, and Myrtle. As for others, they are of the nature of corne and pulse; for the one groweth in the eare or spike alone, the other by the sides, and not otherwise. The Date tree onely (as hath been said before) conteineth fruit within certain pellicles, and the same hangeth downe in clusters after the manner of grapes. Other trees beare their fruit under the leafe for their safeguard and defence, except the Fig tree, which hath her Figs above the leafe, because it is so large and overshadowie. Moreover, the leafe of the Figge tree commeth forth after the Figge. One notable thing is reported of a kind of Figge trees, in Cilicia, Cyprus, and Hellas, to wit, that they have this propertie singular by themselves, To bring foorth their perfect Figs under leafe, and their greene abortive Figs that come to no proofe, after the leafe. The Figge tree beareth moreover certaine hastie Figs, which the Athenians call Prodromos, *i.* vant-courriers or forerunners, because they be long ripe before others. The Laconian Figge trees bring the faireſt and greateſt Figs.

Chap. xxvii.

Of trees that beare twice and thrice in one yeere. Also what trees sooneſt wax old: and of their ages.

IN the same countries above-named, there be Figge trees also that beare Figges twice in one yeare. And in the Island Cea, the wild Figge trees beare thrice in the same yeare: for the second encrease is put foorth upon the first, and the third upon the second: and by this third fruit, the Figges of the tame Figge tree receive their maturitie by way of caprification: and those wild greene Figgs of theirs come foorth above the leafe. Moreover, there be some Pyrries and Apple trees that bring forth fruit twice in a yeere: as also there bee others of the hastie kind, which beare both Peares and Apples betimes in the yeare. There is a kind of Crab tree also or Wilding, that in like manner beareth twice a yeere; and the latter fruit is ripe presently after

A after the middeſt of September, eſpecially in places lying well upon the Sunne. As touching Vines, there bee of them alſo, that after a ſort beare three times in the yeare, which thereupon men call Inſanas, [*i.* The mad or fooliſh Vines:] for whiles ſome of the grapes bee ripe, others begin to ſwell and waxe big, and a third ſort againe are but then in the flower. *M. Varro* writeth, That in Smyrna by the ſea ſide there was a Vine which bare fruit twice a yeare, as alſo an Apple-tree in the territorie of Conſentia. But this is an ordinarie thing throughout all the countrey about Tacapa in Affrica, and never is it ſeene otherwiſe there, ſo fertile is the ſoile; but thereof will we write more at large hereafter in another place. As for the Cypreſſe trees, they faile not but come with fruit thrice in one yeare: and their Berries bee gathered in Ianuarie, May, and September, and all of a diverſe bigneſſe, one from the other. Over and be-
B ſides, the very trees themſelves are not laden with fruit after one and the ſame manner: for the Arbut or Strawberrie tree is more plenteous in the head, & toward the top: the Oke, the Walnut-tree, Fig-tree (and namely that which beareth the unſavourie great figges Mariſcæ) are more fruitfull beneath. Generally, all trees the elder they are, the ſooner they beare and make more haſt to ripen their fruit; the rather alſo, if they grow in a ground leane and expoſed to the Sun. Contrariwiſe, trees that bee wild are later in bearing than other: and ſome of them never yeeld fruit fully ripe. Moreover, ſuch trees under which the ground is tilled and laid hollow, have their fruit ſooner ripe, and are more fruitfull withall, than thoſe that are neglected and not looked unto. Beſides all this, there is a difference in trees as touching bearing their fruit, according to the age: for the Almond tree and the Pyrrie are moſt fertile when they be old, as alſo Maſt trees, & a cer-
C taine kind of Fig-trees. All others, the younger they are, the more fruitfull they be, howbeit, later it is ere their fruit bee ripe: a thing moſt plainely to bee obſerved in Vines. For the better wine commeth from the elder Vines: but more plentie from the younger. As for the Apple-tree, it becommeth of all other ſooneſt old, and in that age the fruit is nothing ſo good as in youth: for both leſſer be the Apples, and alſo more worme-eaten, inſomuch as the very worms will breed in them upon the tree. The Fig is the fruit alone of all trees, that needeth ſome helpe of *Phyſick to ripen. And this may be noted for a ſtrange and miraculous thing in them, That the latter figs be in more price than the haſtie and early ripe, and that there ſhould bee more reckoning made of prepoſterous and artificiall things beſide the courſe of kind, than of the naturall. Alſo, this is a generall rule, Whatſoever tree is exceeding fruitfull, and beareth moſt, the ſame continueth
D leaſt while, and ſoone waxeth old. Yea, and ſome of them are to be ſeene for to die right out, and that very quickly, becauſe they enjoied ſo favourable a ſeaſon, to cauſe them ſo to ſpend themſelves with bearing; as we may marke moſt eaſily in Vines.

*To wit, by caprification.

Chap. xxviii.

Of the Mulberrie tree.

COntrariwiſe, the Mulberrie tree laſteth long, and is very late ere it ſeemeth old. For why? it is not given greatly to beare fruit, neither is overloden with Mulberries. To conclude, looke what trees have a curled graine in the wood, as the Maple, Date-tree, and Poplar, they continue a long time before they decay. And in one word, ſuch as have their roots digged or delved often and laid bare about, are not long lived, but ſoone age and decay.

Chap. xxix.

Of wild trees.

AS for wild trees, they endure longeſt of all others. And generally, as carefull tending and looking to trees, maketh them more fertile: ſo there is nothing ſooner bringeth age upon them, than fruitfulneſſe and much bearing. Hereupon it is likewiſe, that ſuch trees both bud and alſo bloſſome ſooner than others, yea, and ordinarily their fruit is ripe before the reſt: in regard whereof, they are more ſubject to the injurie of the time and the weather, which cauſeth alſo divers and ſundrie infirmities. Moreover, as wee have ſaid alreadie in the chapter of Maſt-trees, there be many that bring forth fruits of different ſorts: among which may be reckoned the Lawrell, with her variable flowers and Berries growing ſo thicke; and principally the barren of that kind, which beareth nothing elſe, and therefore is eſteemed of ſome the male. The Hazels alſo

so and Filbard trees, besides, their nuts doe carie certaine chats with a callous substance of skales joined one within another, but good for nothing.

Chap. xxx.

Of the Box-tree: the Greeke Beane or the Lotus.

All this *Theophrastus* reporteth of Ilex, and not of Buxus.

AMong these is to bee raunged the Box-tree, which bringeth forth the most varietie of all others. For it putteth forth a seed of her owne, also, a graine which they call Carthegon: besides, on the North side Misselto, and on the South Hyphear: whereof wee will write anone more at large: so that otherwhiles a man shall find foure divers things upon the Boxe all together.

Moreover of trees, some be simple or single, to wit, such as from the root have one trunke or bodie, and no more, and yet many boughes and braunches; as the Olive, Fig-tree, and the Vine: others be of a shrubs kind, and put forth many shoots from the root besides the maine trunke, as the Rhamne-thorne Paliurus, and the Myrtle. In like manner the Hazell nut-tree. Howbeit, the better is the tree and more plenteous in fruit, when it is well braunched from the bodie, and hath not those suckers from the root. Yee shall find some againe have no principall stocke at all, as we may see in a kind of Boxe, and a certaine Lotus beyond sea. Others beforked in twain, yea, in five, immediately from the root: and yee shall meet with those that put up many trunkes out of the earth, but braunch not into boughes, as namely, the Elders; as also with others that forke not, nor are devided at all, howbeit, they be full of armes and boughes, as the Pitch-trees. Moreover, some there be which have their boughs disposed in good order, as the Pitch-tree, Firre, or Deale: others againe be as disorderly, as the Oke, Apple-tree, and Pyrrie. As for the Firre verily, where it is devided into boughs, they grow directly upright unto heaven, & spread not in breadth about the sides. But a strange and wonderous thing it is of this tree, that if it bee headed, or the tops onely of those armes cut off, the whole dieth thereupon: but if they bee lopped off close to the bodie, it continueth still alive. Nay, in case it be cut under the place where the braunches put forth, the stocke or stumpe that is left, will take no harme by it, but remaine and live: crop the head onely thereof, and the whole tree dieth. To proceed, some trees spread into armes immediately from the root, as the Elme, others branch onely toward the top, as the Pine, and the Greek Beane, which at Rome for the pleasant tast of the fruit, resembling cherries very much, although K it be of a wild nature, they call Lotus. This tree is much planted about faire houses, in the court yards, especially because the boughs spread so large; for albeit the stock or bodie it selfe bee but very short and small, yet it brancheth so, as that it yeeldeth much shade: yea, and oftentimes the boughs reach to the neighbour housen. But there is not a tree againe that maintaineth this shade a lesse while: for when Winter is once come, the leaves shed, and then it admitteth the warme Sunne for it. Moreover, there is not another tree that beareth a fairer barke, nor more pleasant to the eie, nor that carieth either longer boughs, and more in number than it, or stronger: a man that seeth them, would say they were so many trees by themselves. As touching the use and commodities of this tree, the barke serveth to colour skins and leather: the root to die wooll. And as for the fruit or Apples that it beareth, they are a speciall kind by themselves: for all L the world they resemble the snouts or muzzles of wild beasts, and many of the smaller sort seeme to hang to one that is bigger than the rest.

As concerning boughs of trees, some are tearmed blind, because they put not forth certaine eies or chits where they should bud: which happeneth sometime by a naturall defect, when they are not of validitie to thrust out a bud; otherwhiles it is occasioned by some wrong and injurie done, namely, when they be cut off, and in the place of the cut, there groweth as it were a callous skar that dulleth the vertue of the tree. Furthermore, looke what is the nature that forked trees have in their boughs, the same hath the Vine in her eies and burgeons; the same also have canes and reeds in their joints and knots. Over and besides, all trees toward their root, and the neerest to the ground, are thicker than elsewhere. Some run up altogether in height, and therein shew M their growth, as the Firre or Deale tree, the Larch, Date-tree, Cypresse, Elme, and generally all that rise up in one entire stocke, and are not devided. Of those also that branch and put out many boughes, there is a kind of Cherry-tree that is found to beare armes like beames fortie cubites long, and two foot in thickenesse square throughout the whole length.

Chap.

Chap. xxxi.

Of the Boughs, Barke, and Roots of trees.

THere are trees, that immediatly from the root thruſt out boughs and branches, as doe the Apple-trees. Some be covered with a thin rind, as the Lawrell and Line-tree : others with a thicke barke, as the Okes. In ſome a man ſhall find the barke even and ſmooth, as in the Apple-tree and Fig-tree: the ſame in others is rough and rugged, as is to bee ſeene in Okes and Date-trees. And ordinarily, all old trees have more riveled barkes and furrowed, than the younger. In many trees, the Barke naturally dooth breake and cleave of the owne accord, and namely in the Vine. From ſome it ſhaleth and falleth off, as from the Apple-tree and the Arbut. The Corke and the Poplar have a fleſhie and pulpous barke: the rind of the Vine and the reed, is made in manner of a membrane or thin skin. In Chery-trees it is as ſlender as Paper, and runneth into rolls: but Vines, Lindens, and Firs, are clad with tunicles and coats of many folds. In ſome again the rind is but ſingle, as in the Fig-tree, and the cane or reed. And thus much of Barke.

There is as great difference in the root. For the Fig-tree, the Oke, and the Plane, have great ſtore of roots and large ſpurns: contrariwiſe, in the Apple-tree they are ſhort and ſmall. The Fir and Larch have one tap root and no more : for upon that one maine maiſter-root they reſt and are founded; howbeit, many ſmall ſtrings and petie ſpurns ſhoot out of the ſides. In the Bay-tree the roots be more groſſe and unequally emboſſed, & likewiſe in the Olive, which alſo ſpreadeth out into many branches. But thoſe of the Oke bee of a carnous ſubſtance: and verily, all the kind of Okes doe root deepe into the ground. Certes, if wee give credite to *Virgill*, that ſort of them which are called Eſculi, goe down as deepe into the earth with their roots, as they ariſe & mount above ground with their heads. The roots of the Apple-tree, Olive, and Cypreſſe, lie very ebbe, and creepe hard under the ſourd of the ground. Moreover, there bee roots that runne direct and ſtreight, as thoſe of the Bay and Olive: there be againe that wind and turne as they goe, as thoſe of the Fig-tree. Some are all overgrowne and full of hairie ſtrings, as the Firre root, and many others of wild trees that grow in forreſts: from which the mountainers uſe to plucke thoſe fine fibres and ſmall threds, wherwith they twiſt goodly faire paniers, covers for flaggons and bottels, and worke many other veſſels and pretie deviſes. Some* writers hold opinion and have put down in their bookes, that no roots goe lower into the earth, than that the Sunnes heat may pierce unto them and give them a kind warmth; the which is more or leſſe, ſay they, according to the nature of the ſoile, as it is either lighter and leane, or maſſier, richer, and faſter compact. But I take this to be a meere untruth. This is certaine that wee find in auncient writers, that a young Firre, when it was to be tranſplanted and ſet againe, had a root that went eight cubits within the earth; and yet it was not digged up all whole, but broken in the taking up, and left ſomewhat behind. The roots of Citron trees are biggeſt of all other, and ſpread moſt. Next to them are thoſe of the Planes, Okes, and other Maſt-trees. Some trees there be, the roots whereof like better and live longer, the more ebbe that they lie within the upper face of the ground, and namely, Lawrels; and therefore they ſpring freſh againe, and put forth better, when the old ſtocke is withered and cut away. Others hold, that trees which have ſhort ſtumped roots, doe ſooner decay, & live leſſe while. But deceived they are, and may bee reproved by the inſtance of Fig-trees, which live leaſt while, and yet their roots are longeſt of any other. I ſuppoſe this alſo to bee as falſe, which ſome have held and delivered in writing, That the roots doe diminiſh and decay, as the trees doe wax old: for the contrarie hath been ſeene by an aged Oke, which by the violent force of a tempeſt was overthrowne, the root whereof tooke up a good acre of ground in compaſſe.

* namely, *Theophraſtus.*

Moreover, a common thing it is and ordinarie, to replant and recover many trees that have been blowne downe and laid along: for they will rejoine, knit againe, and revive, by meanes of the earth, even as a wound doth unite by the ſolder of a callous cicatrice. And this is a moſt uſuall and familiar practiſe obſerved in the Planes, which by reaſon of their great heads ſo thicke of boughs, gather winds moſt, and are ſooneſt ſubject to their rage : if any one of them by that meanes bee fallen, they lop their boughs, and diſcharge them of their weightie load, and then ſet them upright againe in their owne place, as it were in a ſocket, and they will take root and proſper. And in good faith, this hath been done heretofore alreadie in Walnut trees, Olives, and many other, to the like proofe.

Chap.

Chap. xxxii.

Of certaine prodigious trees, and presages observed by them. By what meanes trees grow of their owne accord. That all plants grow not every where: and what trees they be that are appropriate to certaine regions, and are not elsewhere to be found.

WE read in Chronicles and records, that many trees have fallen without wind and tempest, or any other apparent cause, but onely by way of prodigie and presage of some future event: and the same have risen againe of themselves without mans helpe. This happened during the warres against the Cymbrians, to the great astonishment of the people of Rome, who thereupon gathered a fore-tokening of great consequence: for at Nuceria in the grove of *Iuno*, there was an old Elme fell, and after the head was lopped off, because it light upon the very altar of *Iuno*, it arose of it owne accord; and that which more is, immediately upon it put forth blossomes and flourished. And this was observed, That from that very instant, the majestie of the people of Rome began to take heart, revive, and rise againe, which had been decaied and enfeebled by so many and so great losses that the Romanes had received. The like chanced (by report) neare the citie Philippi, unto a Willow tree which was fallen downe, and the head of it cut off cleane: semblably, to an Aspen tree at Stagyræ, neare unto the colledge or publick place of Exercise there. And all these were fortunate presages of good lucke. But the greatest wonder of all other was this, of a Plane-tree in the Isle Antandros, which was not onely fallen, but also hewed and squared on all sides by the Carpenter; and yet it rose againe by it selfe, and recovered the former greenenesse and lived, notwithstanding it bare fifteene cubits in length, and foure elns in thicknesse or compasse.

All trees that we are beholden unto the goodnesse of Nature for, wee have by three meanes: For either they grow of their own accord, or come of seed, or else by some shoot springing from the root. As for such as we enjoy by the art and industrie of men, there bee a great number more of devises to that effect: whereof wee will speake apart in a severall booke for that purpose. For the present our treatise is of trees that grow in Natures garden onely, wherein shee hath shewed her selfe many waies after a wonderfull manner, right memorable.

First and formost, as we have shewed and declared before, every thing will not grow in every place indifferently: neither if they bee transplanted, will they live. This happeneth sometimes upon a disdaine, otherwhiles upon a peevish frowardnesse and contumacie, but oftener by occasion of imbecilitie and feebleneſſe of the very things that are remooved and translated: nay, one while the climate is against it, and envious; otherwhiles the soile is contrarie thereunto. The Baulme tree can abide no other place but Iurie. The Assyrian Pome-Citron tree will not beare elsewhere than in Syria. As for the Date-tree, it scornes to grow under all climates: or, if it bee brought to that passe by transplanting, it refuseth to beare fruit. But say, that it fortune by some meanes, that she giveth some shew and apparence of fruit, shee is not so kind as to nourish and reare up to perfection, that which she brought forth, forced against her will. The Cinnamon shrub hath no power and strength to endure either the aire or earth of Syria, notwithstanding it be a neare neighbour to the naturall region of her nativitie. The daintie plants of Amomum or Spikenard, may not away with Arabia, albeit they be brought out of India thither by sea: for king *Seleucus* made triall thereof: so strange they are to live in any other countrey but their own. Certainely, this is a most wonderfull thing to bee noted, That many times the trees for their part may be entreated to remove into a forraine countrey, and there to live; yea, and otherwhiles the ground and soile may bee perswaded and brought to accord so well with plants (bee they never such strangers) that it will feed and nourish them; but unpossible it is to bring the temperature of the aire, and the climate, to condiscend thereto and bee favourable unto them. The Pepper-trees live in Italie; the shrub of Casia or the Canell likewise in the Northerly regions; the Frankincense tree also hath been knowne to live in Lydia: but where were the hote gleames of the Sunne to be found in those regions, either to drie up the watterish humor of the one, or to concoct and thicken the gumme and rosin of the other? Moreover, there is another marvell in Nature, welneere as great as that, namely, that she should so change and alter in those same places, and yet exercise her vertues and operations otherwhiles againe, as if there were no change nor alte-

alteration in her. She hath assigned the Cedar tree unto hote countries: and yet we set it to grow in the mountaines of Lycia and Phrygia both. Shee hath so appointed and ordained, that cold places should be hurtfull and contrarie to Bay-trees, howbeit, there is not a tree prospereth better, nor groweth in more plentie upon the cold hill Olympus, than it. About the streights of the Cimmerian Bosphorus, and namely, in the cittie Panticapæum, both king *Mithridates*, and also the inhabitants of those quarters, used all meanes possible to have the Lawrell and the Myrtle there to grow, onely to serve their turnes when they should sacrifice to the gods: it would never be, did they what they could: and yet even then, there were good store of trees there growing of a warme temperature; there were Pomgranates and Fig-trees plentie; and now adaies there bee Apple-trees and Pyrries in those parts, of the best and daintiest sort. Contrariwise, yee shall not find in all that tract any trees of a cold nature, as Pines, Pitch-trees, and Firres. But what need I to goe as farre as to Pontus for to averre and make good my word? Goe no farther than Rome, hardly and with much adoe will any Chestnut or Cherie-trees grow neare unto it, no more than Peach-trees about the territorie of Thusculum. And worke ynough there is to make Hazels and Filbards to like there: turne but to Tarracina thereby, yee shall meet with whole woods full of Nut-trees.

Chap. xxxiii.

Of the Cypresse tree: That oftentimes some new plants doe grow out of the ground, which were never knowne to be there before time.

THe Cypresse hath beene counted a meere stranger in Italie, and most unwilling there to grow, as wee may see in the workes of *Cato*, who hath spent more words, and made oftener mention of the Cypresse alone, than of all other trees whatsoever. Much ado there is with it before it come up; and as hard it is to grow, and when all is done, the frut is good for nothing. The Berries that it beareth, bee wrinckled, and nothing lovely to the eie; the leaves wherewith it is clad, bitter in tast; a strong and violent smell it hath with it; not so much as the very shade thereof is delectable and pleasant; and the wood but small & not solide, but of an hollow substance; insomuch, as a man may raunge it among the kinds of shrubs. Consecrated is this tree to *Pluto*; and therefore men use to set a bough thereof as a signe, before those houses wherein a dead corpes lieth under bourd. As touching the female Cypresse, it is long ere she beareth. The Cypresse tree for all this, in the end growing up to a pyramidall form sharpe pointed, is not rejected but much set by, if it were for nothing else but to stand betweene every row and ranke of Pine-trees: howbeit, now adaies it is ordered with cutting and clipping for to grow thicke in borders about garden quarters along the allies, also to climbe upon walls in manner of seeling: and being thus kept downe, it is by this meanes alwaies small and tender. Moreover, thereof are drawne many vinets and borders about storie-workes in colours: for so fine is the leafe, so short & greene withall, that it may be brought in a traile to wind about pictures either of hounds and hunters, or of ships and sailers, or any counterfets and images whatsoever, most daintily.

Two sorts there are of the Cypresse tree. First, that which runneth up into a pyramidall point, winding upward as a round spire, which also is called the female. As for the male, it sendeth out braunches, and spreadeth broad: it is lopped also, and serveth in frames to beare up Vines. Both the one and the other is suffered to grow for perches, railes, and plankes, to be made of their boughs when they are cut. Once in thirteene yeares there is made a fall, and not one of those but are sold for a Romane denier apeece. A wood thereof planted in this manner, is of all others most gainefull, and yeeldeth greatest profite: insomuch, as in old time they were wont commonly to say, That one fall of such Cypresse poles would yeeld a man a portion sufficient to give with his daughter in mariage.

The Island Candie is the naturall countrey of the Cypresse tree, howsoever *Cato* hath called it a Tarentine tree: haply, because it came thither first. In the Isle Ænaria, the Cypresse trees spring againe after they bee cut downe to the roots. But in Candie, looke what ground soever a man doth breake up and plough, unlesse he sow or set it with some other thing, Cypresses will come up, and presently shew above ground. In many places also of that Isle, they spring and grow of themselves, even in ground otherwise untilled; and principally in the mountaines of Ida; and those which they call the white Hils: upon the very crests and tops whereof, which are

alwaies

alwaies covered with snow, they are to be seen in greatest plentie. A wonderfull thing, considering that in all other places they love warmth, and without it, will not grow: and besides, when they have met with a familiar ground unto them, yet they care not much for it, but disdaine so kind a nource: whereby a man may see, that not onely the nature of the soile, and the ordinarie power of the climat serveth much for these plants, but also certaine sodaine and temporarie impressions of the aire doe wonderfully worke in this case: for some showers there bee, that oftentimes doe bring seeds with them and engender plants. The same rains do fall sometime after one certaine manner; otherwhiles also in such straunge sort, as men are able to give no reason thereof: A thing that befell to the countrey about Cyrene in Barbarie, at what time as the hearb Laserpitium (which beareth the gum Benjoine) grew there first: as hereafter we will write more at large in our treatise of Hearbs. Moreover, about the 430 yeare after the foundation of Rome citie, there sprung up a very forest or wood neare unto the same citie, by reason of a certaine thicke and glutinous showre like to Pitch, that then fell.

Chap. xxxiiii.

Of Ivie.

It is said, that now the Ivie tree groweth also in Asia: and yet *Theophrastus* in his time delivered the contrarie, and affirmed, That neither it was to bee found there, nor yet throughout all India, but only upon the mount Merus. Over & besides, it is reported, that *Harpalus* did what he could to store the countrey of Media therewith, but all in vaine. And as for *Alexander* the Great, when he returned from out of India with victorie, for the rareneſſe therof he would have all his souldiours go in a sumptuous shew, wearing chaplets therof upon their heads; resembling herein prince *Bacchus*, in solemnities and high feasts of which god, the people of Thracia even at this day are furnished from this tree, and doe with Ivie set out and garnish the heads of their launces, pikes, and javelins, their mourrons also and targuets.

An enemie is Ivie doubtlesse to trees, and generally to all plants and sets whatsoever: it cleaveth and breaketh sepulchres built of stone, it undermineth citie walls; good only to harbour serpents, and most comfortable for their cold complexions: so that I cannot chuse but marveile much that it should bee honoured at all, and accounted of any worth. But to enter into a more particular consideration and discourse of Ivie, two principall kinds are found thereof, like as of all other trees, to wit, the male and the female. The male is described to bee a more massive and greater bodie, to be clad with a harder and fattier leafe, and to shew a flower inclining to purple: and yet the flower of them both, the male as well as the female, doth resemble that of the wild Rose or Eglantine, save that it hath no smell at all. These generall kinds containe each of them three particular sorts: for there is the black & the white Ivie, & a third besides named Helix. And yet we must admit other subdivisions of these also: for of the white, there is one sort that beareth white fruit onely, and another that hath white leaves withall: moreover, of such as carrie only white fruit, one kind hath big beries growing thicke togither, and bunching round in manner of grapes, which clusters be called of the Greeks and Latins Coryuti. A second sort there is of the white Ivie, named Selenitium, which beareth smaller beries, and those not so close set and thicke couched togither. Semblably, it is to be said of the black: for there is an Ivie that beareth also a blacke graine or seed: another with a fruit of a Saffron colour; and hereof are the guirlands made which Poets weare: some call it Nysia, others Bacchica: the leaves of it are not altogither so blacke, but it beareth the greatest bunches and biggest beries of all the blacke kind. And verily of this Ivie there be some Greeke writers that make two sorts, according to the divers colours of the beries: for, the one they call Erythranus, [*i.* the Red;] the other Chrysocarpos, as one would say, the golden-berry Ivie. Now as touching the rampant or climbing Ivie, Helix, there be many and sundrie sorts thereof, differing in their leafe especially: for first and foremost the leaves of this Ivie are small, cornered, and better fashioned than the rest, which in deed are but of a plaine and simple making. There is a difference likewise in the length betweene every knot and joynt, but especially in this, that it is barrain and beareth no fruit at all. And yet some there be, who attribute that to the age, and not to a severall kind of Ivie by it selfe; saying, That the same which at first was Helix, and clasped trees, in tract of time chaunged the leafe and became a very Ivie tree: but foully they are deceived, and disprooved plainly they may be by this,

That

That of the ſaid claſping Ivie Helix, there be many kinds, and three principall above the reſt. The firſt, of graſſe greene colour, which groweth moſt common: the ſecond, with a white leafe: and the third, called alſo the Thracian Ivie, which hath leaves of divers colours. The foreſaid greene Ivie is fuller of leaves, and thoſe finer and ſet in better order than others; wheras the contratie is to be ſeene in the white kind: alſo in the third ſort with varietie of colours, ſome have ſmaller and thinner leaves, couched likewiſe in good order, and thicker growing; whereas in the middle kind, no ſuch thing may be obſerved. Over and beſides, the leaves of Ivie are bigger or leſſe, ſpotted alſo and marked; in which regard one differeth from another. Among the white Ivies, ſome bee whiter than other. The greene Ivie, groweth moſt of all others in length: the white killeth trees, for by ſucking and ſoking all the ſap and moiſture out of them, it feedeth and thriveth ſo well it ſelfe, that it becommeth in the end as big as a tree. A man may know an Ivie being come to his perfection, by theſe ſignes: The leaves are very big and large withall; the tree putteth foorth young ſhoots ſtraight, whereas in others they be crooked and bend inward: the berries alſo ſtand in their cluſters directly upright. Moreover, whereas the branches of all other Ivies be made like unto roots, this hath boughs ſtrong and ſturdie above the reſt; and next unto it, the blacke kind: howbeit this propertie hath the white Ivie by it ſelfe, That amid the leaves it putteth forth armes that claſpe and embrace the tree round on every ſide: which it doth upon walls likewiſe, although it cannot ſo well compaſſe them. And hereupon it is, that although it be cut aſunder in many places, yet it continueth and liveth ſtill: and looke how many ſuch armes it hath, ſo many heads likewiſe of roots are to be ſeene, whereby it maintaineth it ſelfe ſafe and ſound; and is beſides of that force, as to ſucke and choke the trees that it claſpeth. Furthermore, there is gteat diverſitie in the fruit, as well of the white as the blacke Ivie. As for the reſt, the berries of them are ſo exceeding bitter, as no bird will touch them. And yet there is one kind more of Ivie, which is very ſtiffe and ſtandeth alone of it ſelfe without any prop to beare it up: & this of all others only, is thereupon called Ciſſos, or Ivie in deed. Contrariwiſe, Chamæciſſos, [*id eſt*, ground-Ivie] is never knowne but to creepe along the ground.

Chap. XXXV.

Of the Bind-weed or Ivie called Smilax.

Like unto Ivie, is that plant which they call Smilax, or rough Bind-weed. It came firſt out of Cilicia, howbeit more commonly it is to be ſeene in Greece: it putteth forth ſtalkes ſet thicke with joynts or knots, and thoſe thruſt out many thornie braunches. The leafe reſembleth Ivie, and the ſame is ſmall, and nothing cornered: from a little ſtele that it hath, it ſendeth forth certain pretie tendrils to claſpe and wind about: the flower is white, and ſmelleth like to a Lillie: it beareth cluſters comming nearer to thoſe grapes of the wild vine Labruſca, than to the berries of Ivie; red of colour, whereof the bigger containe within them three kernels or pepins apeece, the ſmaller but one, and thoſe be hard and blacke withall. This Smilax is not uſed in any ſacrifices or divine ſeruice of the gods, nor ſerveth for guirlands and chaplets; for that it is held to be dolefull and ominous, or of an unluckie preſage, by occaſion of a certaine young ladie or damſell of that name, who for the love of the young gallant and knight *Crocus*, was turned into this ſhrub or plant, retaining ſtill her name: which the ignorant people not knowing, but taking it for a kind of Ivie, ſticke not to make coronets thereof; profaning by that meanes many times their high feaſts and ſacred ſolemnities: and yet who woteth not with what chaplets Poëts are crowned, and what guirlands prince *Bacchus* or *Silenus* uſed to weare? Of this Smilax are made certain manuell writing-tables. And this propertie moreover hath the wood thereof, That if a man hold it cloſe to his eare, he ſhall heare it to give a pretie ſound.

But to returne againe to the Ivie indeed, it hath (by report) a ſtraunge and wonderfull vertue to trie wines, whether they bee delaied with water or no: for make a cup of Ivie wood, and put wine thereinto, all the wine will ſoke and run through, but the water (if any be mingled therwith) will tarie behind.

Chap. XXXVI.

Of Reeds, Canes, and other water ſhrubs.

IN this diſcourſe as touching plants that love cold places, it will not be amiſſe to treat of thoſe that grow in waters. Among which, the Reeds and Canes may bee raunged in the firſt place:

* for Arrowes and Darts.
* for Writing-pens.
* for Flutes and Pipes.

for necessarie they bee in time both of * warre and * peace: they have their use besides, and are accepted among the *delightsome pleasures of this world. Moreover, in the Northern regions, the people use therewith to cover and thatch their houses: and this kind of rouse will last many ages, if it be laid with a thicke coat, even upon high and stately houses. In other parts also of the world, they are woont with it to make their arch-rouses, and hanging floores of most slight worke. As for Canes particularly, and those of Ægypt by name, which have a certaine resemblance of the Papyr reed in Nilus, they serve for writing-paper. Howbeit those of Gnidos, and which grow in Asia along the lake or meere of Anaia, be held for the best. As for ours here in Italy, they are of a more spungeous substance and gristly matter, apt to sucke and drinke up any liquor. The same within-forth is full of holes and concavities, but converted aloft into a fine woodie rind, and in time becommeth drie, fast, and hard. Apt it is to cleave, and the clifts evermore carie with them a very sharpe edge; and besides, it is full of joynts. Now this woodie substance being thus distinctly parted by knots, runneth alwaies even and smooth, growing smaller and smaller untill it proove sharpe pointed in the top; with a head consisting of a good thicke downe or plume, which serveth also to right good purposes: for either in stead of feathers they use to stuffe beds therewith in common Innes; or when it is growne hard and hath a slimie callositie about it, they in Picardie and those nether-lands doe stampe it, and therewith calfret or calke the joynts of their ships, betweene the ribs and plankes: and herein it hath no fellow, for it taketh faster hold than any glew, and for filling up any rifts and chinkes, no solder so strong, no pitch so sure and trustie. Of Reeds, the Easterlings make their shafts; and archers they be that fight their battailes and determine all quarels. These shafts they arme with sharpe barbed arrow heads in manner of fish-hookes, which wound with a mischiefe, because they cannot be drawne out of the bodie againe: and to make these arrowes flie the faster and kill more presently, they set feathers unto them. Now say that a shaft be broken as it is set fast in the bodie, that end without the flesh will serve againe to be shot: and so inured are the people in those parts to these kind of weapons, so practised withall in discharging of them so nimbly, that a man seeing how thick the shafts flie in the aire, would say they were a cloud of arrowes that shadowed the very sunne. And therefore when they goe to battaile, they wish ever for faire weather and Sunne-shine dayes. Winds and raine, as most adverse unto their warres, they cannot abide: then are they quiet and rest in peace, full sore against their wills, because their weapons at such a time will not serve their turne. Certes if a man would fall to an exact reckoning and æstimate of Æthyopians, Ægyptians, Arabians, Indians, Scythians, and Bactrians, of so many nations also of the Sarmatians, and other East countries, togither with all the kingdomes of the Parthians, hee should find, that the one moietie or halfe of the world hath been vanquished and conquered by the meanes of arrowes and darts, made of Reeds. The Candiots above all others, were so readie and perfect in this kind of feat, that the overweening of their owne skill, and the confidence which they had in this manner of service, made them too bold, and was in the end their owne overthrow. But herein also, as in all other things else whatsoever, Italie hath carried the name, and woon the prize: for there is not a better Reed growing for to make shafts, than that which is found along the Rhene, a little river running under Bononia: verie full of marow or pith; stiffe also it is and weightie withall; it cutteth the aire, it flyeth away most swiftly; and last of all, it will hold the owne and stand in the weather so countrepoised, that no wind hath any power on it. And those Reeds in Picardie and the low countries, are nothing comparable; ne yet of Candie, how highly soever they bee commended for warre-service. And yet the Reeds that grow in India be preferred before them, and beare the name, which indeed some thinke to be of another nature, considering they be so firme and bigge withall, that beeing well headed with yron, they serve in stead of speares and javelins. In very truth, the Indian Canes for the most part, grow to the bignesse of trees, such as we see commonly in temples, standing there for a shew. The Indians doe affirme, that there is a difference among them also, in regard of sex; and namely, that the substance and matter of the male, is more fast and massie; but that of the female, larger and of greater capacitie within. Moreover, (if wee may beleeve their words) the very Cane betweene every joynt, is sufficient to make a boat. These great Canes doe grow principally along the river Acesine. All Reeds in generall, doe shoot and spring in great number from one root and principall stocke: and the more they bee cut, the better they come againe. The root liveth long, and without great injurie offered unto it, will not die: it also is di-

vided

A vided into many knottie joynts. Thoſe onely of India, have ſhort leaves. But in all of them, the leafe ſpringeth out of the joynt, which embracing the Cane, doth clad it round about with certaine thin membranes or tunicles, as farre as to the middle ſpace betweene the joynts; and then for the moſt part they give over to claſpe the Cane, and hang downward to the ground. As well Reeds as Canes, ſpread their leaves like wings round one after another, on either ſide upon the very joynts, and that in alternative courſe alwaies verie orderly; ſo as if the one ſheath come foorth of the right ſide, the other at the next knot or joynt above it, putteth out on the left, and thus it doth throughout by turnes. From theſe nodoſities, otherwhiles a man ſhall perceive (as it were) certaine little braunches to breake foorth, and thoſe be no other but ſmall and ſlender Reeds.

B Moreover, there bee many kinds of Reeds and Canes: for ſome of them ſtand thicker with joynts, and thoſe are more faſt and ſolide than others, and ſmall diſtance there is betweene the ſame: there be againe, that have not ſo many of them, and greater ſpace there is from the one to the other, and ſuch Canes for the moſt part are of a thinner ſubſtance. Ye ſhall have a Cane all full of holes within, called thereupon Syringias; and ſuch are very good to make whiſtles or ſmall flutes, becauſe they have within them neither griſtly nor fleſhie ſubſtance. The Orchomenian Cane is hollow throughout from one end to the other, and this they call Auleticus, or the pipe Cane; for as the former was fit for flutes, ſo is this better for great pipes. Now you ſhall meet with Canes alſo that ſtand more of the wood, and have but a narrow hole and concavitie within; and this is full of a ſpungeous pith or marow within-foorth. Some be ſhorter, ſome
C longer than other: and where you have one that is thin and ſlender, you ſhall ſpie a fellow to it more groſſe and thicker. That which braunch eth moſt, and putteth foorth greateſt ſtore of ſhoots, is called Donax, and is never knowne to grow but in mariſhes and waterie places, (for herein alſo lyeth a difference) and preferred it is farre before the Reed that commeth up in drie ground. The Archers Reed is a ſeverall kind by it ſelfe (as we have ſhewed before;) but of this ſort, thoſe in Candie have the greateſt ſpaces betweene every joynt; and if they be made hote, they are verie pliable, and will bend and follow which way ſoever a man would have them.

Moreover, Reeds are diſtinguiſhed one from another by the Leafe, not for the number, but the ſtrength and colour. The leaves of thoſe about Lacedæmon, * are ſtiffe and ſtrong, grow- * *Varia*, or *Versicolor*, ποικίλα, *Theoph. i.* of divers colors.
D ing thicker of the one ſide than the other. And ſuch as theſe are thought generally to grow along ſtanding pooles and dead waters, farre unlike to thoſe about running rivers: and beſides, to be clad with long pellicles, which claſpe and climbe about the Cane higher above the joynt, than the reſt doe. Furthermore, there is another kind of Reeds that groweth crooked and winding travers, and not upright to any height, but creeping low toward the ground, and ſpreading it ſelfe in manner of a ſhrub. Beaſts take exceeding great delight to feed thereof, and namely, when it is young and tender, for the ſweet and pleaſant taſt that it hath. Some call this Reed, Elegia.

Over and beſides, there breedeth in Italie alſo among the fennes, a certaine ſalt ſome, named * Adarca, ſticking to the rind or utmoſt barke of Reeds and Canes, onely under the verie * *Calamachne.*
tuft and head: paſſing good it is for the tooth-ach, by reaſon of the hote and cauſticke qualitie
E that it hath like to Senvie or Muſtard-ſeed. As touching the Reed-plots about the Orchomenian lake, I muſt needs write more exactly, conſidering in what admiration they were in times paſt: for in the firſt place, they called that Cane which was the thicker and more ſtrong, Characias; but the thinner and more ſlender, Plotia. And this verily was woont to bee found ſwimming in the Iſlands that floted in the ſaid lake; whereas the other grew alwaies firme upon the bankes and edges thereof, how farre ſoever it ſpred and flowed abroad. A third ſort alſo there is of Canes, which they called Auleticon, for that it ſerveth to make flutes and pipes of: but this commonly grew but every ninth yeare: for the ſaid lake alſo kept that time juſt, and encreaſed not above that tearme; but if at any time it chaunced to paſſe that time and to continue full two yeares togither more than ordinarie, it was holden for a prodigious and fearefull ſigne. The
F which was noted at Chæronia, in that unfortunate battaile wherein the Atheniens were overthrown and defeated: and many times elſe is obſerved to happen about Lebadia, namely, when the river Cephiſus riſeth ſo high, that he ſwelleth over his bankes, and is diſcharged into the ſaid lake. Now during that ninth yeare (whiles the inundation of the lake continueth) theſe Canes proove ſo bigge and ſtrong withall, that they ſerve for hawking poles, and fowlers pearches:

and then the Greeks call them Zeugitæ. Contrariwise, if the water hold not so long, but doe fall and returne back within the year, then the Reeds be small and slender, named Bombyciæ. Howbeit the females of this kind, have a broader and whiter leafe, little or no down at all upon them, and then they are knowne by a pretie name and called Spadones, as one would say, guelded. Of these Reeds were made the instruments for the excellent close musicke within-house: wherein, I cannot passe with silence, what a wonderfull deale of paines and care they tooke to fit them for their tune, and make them to accord: insomuch, as wee are not to be blamed but borne withall, if now adaies we chuse rather to have our pipes and hautboies of silver. And in truth, unto the time of *Antigenes* (that excellent minstrell and plaier upon the pipe) all the while that there was no use but of the plaine musicke and single instrument; the right time of cutting down and gathering these Reeds for this purpose, was about September, when the signe Arcturus is in force: then were they to have a seasoning and preparation for certain yeares, before they would serve the turne: yea and then also much adoe there was with them, and long practise and exercise they asked, before they could be brought into frame and good tune: so as a man might well say, that the very pipes were to be taught their sound and note, by means of certain tongues or quils that strucke and pressed one upon another; and all to give contentment and shew pleasure unto the people assembled at Theatres, according as those times required. But after that musicke came once to be compound, and that men sung and plaied in parts with more varietie and delight, they began to gather these Reeds before mid-Iune, and in three yeares space they had their perfection and grew to their proofe: then were those tongues or holes made more wide and open, for to quaver and chaunge the note the better: and of such are the flutes and pipes made, which be used at this day. But in those times men were perswaded, that there was a great difference in the parts of any Reeds for to serve these or those instruments: in such sort, as that joynt which was next unto the root, they held to be meeter for the Base pipe that was fitted for the left hand; and contrariwise for the Treble of the right hand, those knots that were toward the head and top of the Reed. Howbeit of all others, by many degrees were those preferred which grew in the river Cephisus. Now adaies the Hautboies that the Tuscanes play upon at their sacrifices, bee of Box-wood; but the pipes used in plaies for pleasure only, are made of the Lotos, of asses shankbones, and of silver. The best Faulconers Reeds wherewith they use to chase foules, came from Panhormus: but the Canes for angle-rods that fishers occupie, are brought out of Africk from Abaris. The Italian Reeds and Canes be fittest for to make perches to lay over frames, & props for to bear up vines. Finally, as touching the setting of Reeds, *Cato* would have them to be planted in moist grounds, after they have been first delved and laid hollow with a spade; provided alwaies that the œleth stand three foot asunder, and that there be wild Spatages among, whereof come the tender crops for sallads; for those like well and sort togither with the Canes.

Chap. xxxvii.

Of the Willow or Sallow, eight kinds thereof: and what trees besides the Willow are good for buildings. Also of Briers and Brambles.

MOreover (after the opinion of the said *Cato*) it is good to plant Withies also about river sides, and neare to Reeds: for surely there is not more profit arising from any other tree of the waters, than from it; howsoever the Poplars are well liked and loved of the vines, and doe nourish the good wines of Cæcubum: howsoever the Alders serve in stead of rampiers and strong fences against the inundation and overflowing of rivers, withstanding their forcible eruptions; howsoever they stand in the waters as mures and walls to fortifie the banks, or rather as sentinels to watch and ward in the borders of country farmes; and being cut down to the root, doe multiply the rather, and put forth many shoots and imps as heirs to succeed. And to begin withall, of Sallows there be many kinds: for some there be, that in the head beare pearches of a great length to prop and make trailes for vines to run upon: and the rind or skin as it were pilled from the wood, is as good as a belt or thong to bind or gird any thing withall. Others againe there are, and namely the red Willowes, which carie twigs and rods that are pliable and gentle to wind as a man would have them; fit also for buildings. Ye shall have of these Osiers, some that are very fine & passing slender, wherof are wrought pretie baskets and many other daintie devises; others also that are more tough and strong, good to make paniers, hampers, and a thousand other

A other neceſſarie implements for countrey houſes, and to fit the husband-men. Beeing pilled, they are the fairer and whiter, more ſmooth alſo and gentle in hand, whereby they are excellent good for the more delicate ſort of ſuch wicker ware, and better farre than ſtubborn leather; but principally for leaning chaires, wherein a man or woman may gently take a nap, ſitting at eaſe and repoſe moſt ſweetly. A Willow, the more that it is cut or lopt, the better ſpring will it ſhoot at root, and beare the fairer head. Let that which you cut or ſhred, be ſo little and ſhort withall, that it reſemble a mans fiſt, rather than a bough, the thicker will it come againe: a tree no doubt that would not be ſet in the loweſt ranke, but be well regarded, howſoever we make but baſe reckoning thereof: for ſurely there is not a tree for revenue and profit, more ſafe and certaine; for coſt, leſſe chargeable; and for injurie of weather, in better ſecuritie. Certes *Cato*, among the
B commodities that commend a good ferme or manour, eſteemeth it in the third place, and preferreth the encreaſe and benefit thereby, before the gaine that groweth from Olive rowes, corne fields, and good medowes. Yet hereof wee muſt not infer, that wee are not furniſhed with many other things which will ſerve for bands to bind withall; for we have certain ſorts of Spart or Spaniſh broome, wee have Poplars, Elmes, the Sanguine-ſhrubs, Birch, cloven Reeds, leaves of Cane; as for example in Liguria: the cuttings alſo of the very Vine, and Briars, ſo their ſharpe pricks be cut away, to tie withall; yea and the Hazell wands alſo, ſo they be writhen and twined: wherein a man may ſee a wonderfull propertie, That a wood ſhould be ſtronger for to bind withall, when it it is cruſhed and bruiſed, than whiles it was entire and ſound. All theſe (I ſay) are good for bands, and yet the Willow hath a gift therein beyond all the reſt. The Greek Willow is red,
C and commonly is ſliven for to make withes. The Amerian Oſier is the whiter, but more brittle, and ſoone will cracke, and therefore it is put to that uſe of binding ſound and whole as it groweth, and not cloven through. In Aſia, they make account of three ſorts of Willows: the blacke, which they employ to wind and bind withall, ſo tough and pliant it is: the white, wherewith husbandmen make their wicker paniers and baskets, with other ſuch veſſels for their uſe: as for the third, it is the ſhorteſt of all other, and they call it Helix, or Helice. With us alſo here in Italie, there be as many kinds, and thoſe diſtinguiſhed by their ſeverall names: the firſt, which is of a deepe purple colour, they call the free Oſier or Willow; and that is ſo good for bands: the ſecond, which is more thin and ſlender, is named * Vitelina, for the bright hew that it hath: the third that is ſmalleſt of all three, is the French Willow.

* or, *Vitellinam* rather, for the yellow colour of the yolke of egs.

D To come now to the brittle Ruſhes that grow in mariſh grounds, which ſerve to thatch houſes and to make mats; and the pith whereof when the rind is pilled, maketh wieke for watch-candles, and funerall lights to burne by a dead corps whiles it lieth above ground: they cannot juſtly be reckoned in the ranke either of Shrubs, or Brier-buſhes and Brambles, ne yet of tall plants growing up with ſtems and ſtalkes, no more than among Hearbs and Weeds creeping along the ground; but are to be counted a ſeverall kind by it ſelfe. True it is, that in ſome places there are to be found ruſhes more ſtiffe, hard, and ſtrong, than in others. For not onely mariners and watermen in the river Po doe make ſailes thereof, but fiſhermen alſo of Affrick in the maine ſea: howbeit they hang their ſailes betweene the maſts, from maſt to maſt, after a prepoſterous manner contrary to all other. The Mores alſo doe cover their cottages with Bulruſhes: and ſure-
E ly if a man looke nearely to the nature of them, they may ſeeme to ſerve for that uſe which the Papyr reeds in the neather-land of Ægypt are put unto, about the deſcent and fall of the river Nilus.

As touching Brambles, they may goe among the ſhrubs of the water: ſo may the Elders alſo, which conſiſt of a ſpongeous kind of matter, & yet cannot well be counted among thoſe plants which be tearmed Fenels-gyant: for ſurely the Elder ſtandeth more upon the wood than they doe. The ſhepheards are verily perſuaded, that the Elder tree growing in a by-place farre out of the way, and from whence a man cannot heare a cocke crow out of any town, maketh more ſhrill pipes and lowder trumpes than any other. The Brambles beare certaine berries like the Mulberries, even as the ſweet Brier of another kind, which they call Cynosbatos or the Eglantine,
F carrieth the reſemblance of a Roſe. A third ſort there is of Brambles, which the Greeks call Idæa, of the mountaine Ida. This is the Raſpis: ſmaller it is and more ſlender than the reſt, with leſſe pricks upon it, and nothing ſo ſharpe and hooked. The flower of this Raſpis beeing tempered with honey, is good to be laid to bleared and bloodſhotten eyes; as alſo to the wild-fire or diſeaſe called Saint *Anthonies* fire. Being taken inwardly, and namely drunke with water, it is verie

comfortable to a weake ſtomacke. The Elder beareth certaine blacke and ſmall Berries, full of a G
groſſe and viſcous humor, uſed eſpecially to die the haire of the head blacke. If they be boiled in water, they are good and wholeſome to be eaten, as other pothearbes.

Chap. xxxviii.

Of the juice or humor in trees. The nature of their wood and timber. The time and manner of felling and cutting downe trees.

TRees have a certaine moiſture in their barkes, which we muſt underſtand to bee their verie bloud, yet is it not the ſame, nor alike in all: for that of the Figge trees is as white as milke, and as good as rendles to give the forme to cheeſe. Cherrie trees yeeld a glutinous and gummie humor, but Elmes a thin liquor in manner of ſpittle. In Apple trees the ſame is fattie and viſcous; in Vines and Pyrries, wateriſh. And generally, thoſe trees continue and live longeſt that have ſuch a glewie moiſture in them. In ſumme, there are to bee conſidered in the ſubſtance and bodie of trees, like as of all other living creatures; their skin, their bloud, fleſh, ſinewes, veines, bones, and marrow. For in lieu of their hide is the barke. And I aſſure you, a ſtraunge and marvellous thing it is to be obſerved here in the Mulberrie, that when Phyſicians ſeeke to draw the foreſaid liquour out of it, at ſeven or eight a clocke in a morning, if they ſcarifie or lightly cut the barke with a ſtone, it iſſueth forth, and they have their deſire; but if they cruſh or cut it deeper in, they meet with no more moiſture than if it were ſtarke drie. In moſt trees next to the skin lieth the fat: this is nought elſe but that white ſap, which of the colour is called in Latin Alburnum. As it is ſoft in ſubſtance, ſo is it the worſt part of the wood; and even in the ſtrong Oke, as hard as otherwiſe it is, ye ſhall have it ſoone to putrifie and rot, yea, and quickly to bee worme-eaten. And therefore, if a man would have ſound and good timber, this white muſt be alwaies cut away in the ſquaring. After it, followeth the fleſh of the tree; and ſo the bone, which is the very heart and beſt of the wood. H I

All trees whereof the wood is over drie, beare fruit but each other yeare, or at leaſtwiſe more in one yeare than another, as namely, the Olive tree. A thing obſerved more in them, than in thoſe that have a pulpous and fleſhie ſubſtance, as the Cherrie tree. Neither are all trees indifferently furniſhed with ſtore of the ſaid fat or fleſh, no more than the moſt fierce and furious beaſts. As for the Boxe, Cornell, and Olive trees, they have neither the one nor the K
other, ne yet any marrow at all, and but verie little bloud. Semblably, the Serviſe tree hath no heart, the Elder no carnoſitie, (and yet both of them are ſtored well ynough with marrow, which is their pith) no more than canes or reedes for the moſt part. In the fleſhie ſubſtance or wood of ſome trees, there are to bee found graine and veine both. And eaſie it is to diſtinguiſh the one from the other: for commonly the veines bee larger and whiter; contrariwiſe, the graine (which the Latines call Pulpa) runneth ſtreight and direct in length, and is to bee found ordinarily in trees that will eaſily cleave. And hereupon it commeth, That if a man lay his eare cloſe to one end of a beame or peece of timber, he ſhall heare the knocke or pricke that is made but with a penknife at the other end, bee the peece never ſo long, by reaſon that the ſound goeth along the ſtreight graine of the wood. By this meanes alſo a man ſhall find L
when the timber doth twine, and whether it runne not even, but bee interrupted with knots in the way.

Some trees there be that have certaine hard bunches, bearing out and ſwelling like to kernels in the fleſh of a Swines necke, and theſe knobs or calloſities, have not in them long graine and broad veine, as is aboveſaid: but onely a brawnie fleſh (as it were) rolled round together. And to ſay a truth, when ſuch knurs and calloſities as theſe bee, are found either in Citron or Maple trees, men make great account of them, and ſet no ſmall ſtore by that wood. All other ſorts of tables, when the trees are cloven or ſawne into plankes, are brought into a round compaſſe with the graine: for otherwiſe, if it were ſlit overthwart to make them round againſt the grain, it would ſoone breake out. As touching the Beech, the graine of it runneth croſſe two contrarie waies M
like combe teeth; but in old time the veſſels made of that wood, were highly eſteemed. As for example, *Manius Curius* having ſubdued his enemies, proteſted, and bound it with an oth, That of all the bootie and pillage taken from them, hee hath not reſerved any thing for himſelfe, but onely a cruet or little ewer of Beech wood, wherewith he might ſacrifice unto the gods.

There

A There is no wood but floteth aloft the water, and waveth in length: like as that part which is next to the root, is farre more weightie, ſetleth faſter downe and ſinketh. Some wood hath no veines at all, but conſiſteth onely of a meere graine, ſtreight and ſmall in manner of threds: and ſuch commonly is eaſie to be cloven. There is againe wood which hath no ſuch direct grain, and that will ſooner breake out than cleave, and of this nature is the Olive and Vine-wood. Contrariwiſe, the whole bodie and woodie ſubſtance of the Fig-tree, is nothing but fleſh. The Maſtholme, Cornell, Oke, Tretrifolie, Mulberrie, Ebenie, and Lotus, which have no pith and marrow within, as is beforeſaid, are all heart. All wood for the moſt part turneth to a blackiſh colour. The Cornell tree is of a deepe yellow, whereof are made the faire Bore-ſpeare ſtaves, which ſhine againe, and bee ſtudded (as it were) with knots, and chamfred betweene, both for decencie and
B handſomeneſſe. The Cedar, Larch, and Iuniper wood, is red.

Chap. xxxix.

Of the Larch, the Firre, and the Sapine: the manner of cutting or falling ſuch like trees.

THere is a female Larch tree which the Greekes call Ægis: the wood whereof is of a pleaſant colour, like to honie. Painters have found by experience, that it is excellent good for their tables, both for that it is ſo even and ſmooth, not apt beſides to chinke and cleare; as alſo becauſe it will endure and laſt for ever. And that part they chuſe which is the very heart of it,
C and next the pith, which in the Fir tree the Greekes call Leuſon. In like ſort the heart of the Cedar is hardeſt, which lieth next to the pith or marrow abovenamed (much after the manner of bones in the bodies of living creatures) when the muddie carnoſitie is ſcraped off & taken away. The inward part alſo of the Elder by report is wonderous hard and tough, and they that make thereof ſtaves for Bore-ſpeares, prefer it before any wood whatſoever. For it ſtandeth onely upon skin and bone, that is to ſay, of the rind and heart.

Theophraſtus writeth this of the Cornell tree.

As touching the falling and cutting downe of trees, to ſerve either in temples or for other uſes, round and entire as they grow, without any ſquaring; as alſo for to bark them; the only time and ſeaſon is, when the ſap runneth, and that they begin to bud forth: otherwiſe you ſhall never be able to get off their barke: for barke them not, they will rot and become worme-eaten under
D the ſaid barke, and the timber withall waxe duskiſh and blacke. As for the other timber that is ſquared with the axe, and by that meanes rid from the barke, it would bee fallen or cut downe betweene mid-winter and the time that the wind Favonius bloweth: or, if wee bee forced to uſe the timber before, and to prevent that time, trees may be fallen at the ſetting of the ſtar Arcturus, or of the Harpe ſtar before it. Finally, the utmoſt and laſt time thereof is at the Summer Sunſtead. But for as much as moſt men be ignorant of theſe ſeaſons, and know not when theſe ſtars abovenamed doe either riſe or fall, I will hereafter ſhew the reaſon both of the one and the other in place convenient. For this preſent, as touching the time of felling trees, the common ſort make no more ſcruple, but thinke it ſufficient to obſerve, that no trees which are to be hewne ſquare for Carpenters worke be caſt downe and laid along before they have borne their fruit. As
E for the hard and ſavage Oke, if it bee felled in the Spring, it will be ſubject to the worme: but cut it downe in midwinter, it will neither warpe, nor yet cleave and chinke: being otherwiſe ſubject unto both, namely, as well to caſt and twine, as to rift and gape: a thing incident to the Corke wood, bee it cut downe in as good a ſeaſon as it is poſſible. Moreover, it paſſeth to ſee how much the age of the Moone availeth in this caſe. For it is commonly thought, that timber would not be fallen but in the wane, and namely, in the laſt quarter, from the twentieth day of the Moone, untill the thirtieth. And this is generally received among all good workemen, That the beſt time to cut downe any timber, is in the conjunction of the Moone with the Sunne, even the very day of the change, before ſhe ſheweth new. Certes, *Tiberius Cæſar* the Emperour, gave order to fell the Latch trees that came out of Rhœtia, to repaire and reedifie the bridge that ſerved to repre-
F ſent the ſhew of a navall battell upon the water (which fortuned to be conſumed with fire) juſt at the chaunge of the Moone. Some ſay, that we muſt preciſely obſerve the point of the conjunction, and that the Moone withall be under the earth, when ſuch trees ſhould be felled: which cannot be but in the night. But if it fall out beſides, that this conjunction or change of the Moone, and the laſt day of the winter Sunſtead meet together at one inſtant: the timber then cut downe

will

will last a world of yeares. Next unto it is that timber which is fallen in the daies and signs above rehearsed. Others affirme moreover, that the rising of the Dog star would be considered & chosen for this purpose: for at such a time was that timber felled, which served for the stately hall or pallace of *Augustus*. Moreover, for to have good and profitable timber, the trees would bee cut downe that are of a middle age, for neither young poles nor old runts are fit for durable building. Furthermore, there bee that hold opinion, That for to have the better timber, the trees should have a kerfe to the very heart and pith round about, and so let it stand an end still, that all the humor by that meanes might run out, before they be overthrowne and laid along. And verily, a wonderfull and miraculous thing is reported in old time, during the first Punicke war against the Carthaginians, namely, That all the ships of that fleet which was conducted by Generall *Duellius* the high Admirall, were shot into the sea and under saile, within threescore daies after that the timber whereof they were built, was cut downe in the wood. And *L. Piso* hath left in writing, That against king *Hiero*, there were two hundred and twentie ships made and furnished in five and fortie daies after the timber grew. Also in the second Punicke war, the Armado which *Scipio* emploied, was set aflote and bare saile fortie daies after the fall of the timber. See how forcible and effectuall in all things is the season & opportunitie of time duly taken, especially when need driveth to make speed and hasten apace.

Cato the cheefe and onely man of all others for experience and knowledge in every thing, in his Treatise of all kind of timber to be emploied in building, giveth these rules following, Make thy pressing planke especially of the black *Sapine or Hornbeame tree. *Item*, Whensoever thou meanest to storke up either Elme, Pine, Walnut tree, or any other whatsoever for timber, see thou dig it out of the ground, in the wane of the moone, and that in the afternoone, and take heed in any wise that the wind be not South. *Item*, The right season to fell a tree for timber, is when the fruit is full ripe. *Item*, Beware in any case, that thou neither draw foorth of the ground, nor yet square a tree, when the dew falleth. And a little after. Beware thou meddle not with timber trees but either at the change or full of the Moone. And in no hand, neither storke it up then, nor hew it hard to the ground. But within foure daies after the full Moone, plucke up trees hardly, for that is the best time. *Item*, Be well advised, that thou neither fell, square, nor touch with the ax, any timber that is blacke, unlesse it be drie. And meddle not with it, if either it be frozen, or full of deaw. *Tiberius* the Emperour abovenamed, observed likewise the chaunge of the Moone, for cutting the haire both of head and beard. And yet *M. Varro* gave a rule, That to prevent baldnesse and the shedding of haire, the Barber should be sent for alwaies after the full Moone.

Sapino or, *Carpine.*

But to come againe unto our timber trees. The Larch and Fir, both, but the Fir especially, if they be cut down, bleed a long time after, and yeeld abundance of moisture. Indeed, these twaine of all other bee the tallest, and grow most streight and upright. For Mast poles, and crosse-Saile-yards in ships, the Fir or Deale is commended and preferred before all other, for the smoothnes and lightnesse withall. The Larch, the Fir, & the Pine, have this propertie common to them all, To shew the graine of their wood, running either parted in foure, forked in twaine, or single one by one. For fine Carpentrie and Ioiners seeling within house, the heart of the tree would be cloven or rent. The quarter timber, or that which runneth with foure graines, is simply the best, and more pleasant to be wrought than the rest. They that be skilfull woodmen and have experience in timber, will soone find at the first sight the goodnesse of the wood by the very barke. That part of the Fir tree which groweth next to the earth, is without knots, even and plaine: the same is laid to soke and season in the water, and afterwards the barke is taken off, and so it commeth to bee called Sapinus. The upper part is knottie and harder than the nether, and the Latines name it Fusterna. In summe, what tree soever it be, that side which regardeth the North, is more strong and hard than the other. And generally, the wood of those trees that grow in moist and shadie places is the worse: contrariwise, that which commeth from ground exposed to the Sunneshine is more fast and massie, and withall, endureth a long time. And hereupon it is, that at Rome the Fir trees that come from the nether sea side out of Tuscane, be in better request than those from Venice side, upon the coast of the upper sea.

Moreover, there is great ods betweene Fir trees, in regard of diverse countries and nations where they grow. The best are those of the Alpes and the Apennine hils. Likewise within France there are excellent good Firs upon the mountaines Iura and Vogesus: as also in Corsica, Bithynia, Pontus, and Macedonia. A worse kind of them grow in Arcadia and about the mountaines neare

A neare Ænea. The worſt be thoſe of Pernaſſus,& Eubœa: for in thoſe parts they be full of boughs and grow twined,beſides,they ſoone doe putrifie and rot.

As for Cedars,the beſt ſimply be thoſe that grow in Candie,Affricke,and Syria. This vertue hath the oile of Cedar, That if any wood or timber be throughly annointed therewith,it is ſubject neither to worme nor moth,ne yet to rottenneſſe.

The Iuniper hath the ſame propertie that the Cedar. They prove in Spaine to bee exceeding big and huge,the Berries alſo greateſt of all others.And whereſoever it groweth,the heart therof is more ſound than the Cedar.

A generall fault and imperfection there is common to all wood,When the grain,& the knots run into round balls;and ſuch they call in Latine Spiræ.Alſo in ſome kind of timber, like as in
B marble alſo there bee found certaine knurs like kernils, as hard they be as naile heads, and they plague ſawes,whereſoever they light upon them.Otherwhiles they fall out to be in trees,by ſome accidentall occaſion,as namely,when a ſtone is gotten into the wood,and encloſed within it: or, in caſe the bough of ſome other tree be incorporate or united to the foreſaid wood. There ſtood a long time a wild Olive in the market place of Megara,upon which the hardie and valiant warriors of that citie uſed to hang and faſten their armour, after ſome worthie exploit performed: which in tract and continuance of time were overgrowne with the barke of the ſaid tree,& quite hidden. Now was this a fatall tree unto the ſame citie and the inhabitants thereof,who by way of Oracle were forewarned of their wofull deſtinie and utter ruin; which was to happen,When that a tree ſhould be with young,and delivered of harneis: which Oracle was fulfilled when this tree
C was cut downe,for within the wombe thereof were found the mourrions,jambriers or greives,of brave men in times paſt. To conclude, it is ſaid,That ſuch ſtones ſo found in trees bee ſingular good for a woman with child,to carie about her,that ſhe may goe her full time.

Chap. xl.

Of diverſe ſorts of timber. Of certaine trees of extraordinarie bigneſſe. What trees they be that never be worme-eaten,nor decay and fall. What wood doth endure and continue alwaies good.

D THe greateſt tree that to this day had ever beene knowne or ſeene at Rome, was that,which being brought with other timber for the rebuilding of the foreſaid bridge called Naumachiaria, *Tiberius Cæſar* commanded to be landed and laid abroad in view for a ſingular and miraculous monument to all poſteritie: and it remained entire & whole,untill the time that *Nero* the Emperour built his ſtately Amphitheatre. This peece of timber was of a Larch tree: it contained in length 120 foot, and carried in thickneſſe every way two foot, from one end to the other. Whereby a man may gueſſe and judge the incredible height of the whole tree beſides,to the very top. Such another tree there was to be ſeene in our daies, which *M. Agrippa* left for the like ſingularitie & wonder of men,in thoſe ſtately porches and cloiſters that he made in *Mars* field: and it continued ſtill after the building of the muſter place and treaſurers hall named Diribitorium. Shorter it was than the former by twentie foot, and caried a foot and halfe in
E thickneſſe. As for the Fir tree, which ſerved for a maſt in that huge ſhip,which by the commaundement and direction of *C. Caligula* the Emperour tranſported and brought out of Ægypt, that Obeliske which was erected and ſet up in the Vaticane hill, within the Cirque there, together with the foure entire ſtones which bare up the ſaid Obeliske as ſupporters;it was ſeene of a wonderfull and ineſtimable height above all others: and certaine it is, that there was never knowne to flote upon the ſea a more wonderfull ſhip than it was. She received 120000 Modij of Lentils for the very ballaiſt; ſhee tooke up in length the greater part of the left ſide of Hoſtia harbour: for *Claudius* the Emperour cauſed it there to be ſunke,together with three mightie great piles or dams founded upon it, and mounted to the height of towers, for which purpoſe there was
F brought a huge quantitie of earth or ſand from Puteoli. The maine bodie of this maſt contained in compaſſe foure fadome full. And a common by-word it is, currant in euery mans mouth, that Fir maſts for that purpoſe,are uſually ſold for eight hundred Seſterces apeece,and more monie: whereas for the moſt part plankes which are ſet together and ſerve in ſtead of boats,ordinarily coſt but fortie. Howbeit,the kings of Ægypt and Syria,for default and want of Fir,have uſed(by report)in ſteed thereof Cedar wood about their ſhipping. And verily,the voice goeth of an exceeding

ceeding big one which grew in Cyprus, and was cut downe for a maſt to ſerve that mightie galleace of king *Demetrius*, that had eleven bankes of oares to a ſide; a hundred and thirtie foot it was high, and three fatham thicke. And no marvell, ſince that the pyrates and rovers who haunt the coaſts of Germanie, make their punts or troughs of one entire peece of wood and no more, wrought hollow in manner of a boat, and ſome one of them will hold thirtie men.

To proceed now unto the ſundrie natures of wood. The moſt maſſie and faſt wood, and therefore the weightieſt of all other, by judgement of men, is that of the Ebene and the Boxe: both ſmall trees by nature. Neither of them twain ſwimmeth above the water, no more will the Corke wood, if it be barked, nor the Larch. Of all the reſt, the ſaddeſt wood is that of Lotus, I meane that which at Rome is ſo called. Next to it, is the heart of Oke, namely, when it is rid of the white ſappie wood: the heart (I ſay) which commeth neare to a blacke colour: and yet the Cytiſus or Tretrifolie is blacker, and ſeemeth moſt to reſemble the Ebene. Howbeit, you ſhall have ſome, who affirme that the Terebinths of Syria bee blacker than it. There was one *Thericles* a famous Turner, who was wont to make drinking cups, mazers, and bowles of the Terebinth; which is a ſufficient proofe, that the wood is fine and hard. This wood alone of all others, loveth to bee oiled, and ſurely the better it is for the oile. But a marvellous pretie deviſe there is to ſet a paſſing faire blacke colour, and a ſhining gloſſe upon it; with Walnuts and wild Peares, namely, boiling theſe together, and making thereof a mixture and compoſition to give the ſaid tincture. All theſe trees abovenamed have a ſad and faſt wood. Next to them in that reſpect is the Cornell tree: and yet I cannot properly raunge it in the order of timber trees, ſo ſmall and ſlender it is. Neither is the wood thereof good in manner for nought els but for ſpokes in cartwheeles, alſo to make wedges to cleave wood, and tough pins, which will hold as faſt well neare as yron ſpikes. In like ſort, the Maſt-holme, the Olive both wild and tame, the Cheſtnut tree, the Hornebeame, and the Poplar, be of an hard ſubſtance, and meet for this purpoſe. The wood hereof hath a curled graine like the Maple, and ſurely would bee as good timber as any, but for often lopping the boughs, which gueldeth and deminiſheth the ſtrength. Moreover, many of them there bee, and the Oke eſpecially, ſo hard, that unleſſe they be ſoked firſt in water, it is impoſſible to bore a hole into them with an augoer, nor to plucke forth a naile if it be once ſet faſt, water them as much as you will. Contrariwiſe, the Cedar will not hold a naile. The wood of the Linden tree ſeemeth of all other to be moſt ſoft, and hoteſt withall: for proofe whereof, this reaſon men doe alleadge, becauſe it ſooneſt turneth and dulleth the axe edge. Of a hote nature alſo are the Mulberrie tree, the Lawrell, and the Yvie, and in one word, all thoſe that ſerve to ſtrike fire with. This experiment was firſt found out by ſpies, that goe betweene campe and campe, by ſheepheards alſo in the field: for having not flint evermore readie at hand to ſmite and kindle fire withall, they make ſhift for to rub and grate one wood againſt another, & by this attrition there flie out ſparckles, which lighting upon ſome tinder, made either of drie rotten touchwood, or of bunts and withered leaves, very quickly catch fire, and burne not out. And for this intent, there is nothing better than to ſtrike the Yvie wood, with the Bay. In this caſe alſo the wild Vine (I meane not Labruſca) is much commended: and it climbeth and runneth upon trees in manner of Yvie.

The trees that grow in waterie grounds be coldeſt of all others: but ſuch be tougheſt, & therfore beſt to make bucklers and targuets, the wood whereof, if it bee cut, commeth quickly together, and cloſeth up the gaſh again, & in that regard, much adoe there is to pierce it through with any weapon whatſoever. And of this ſort are Fig trees, Willowes, Lindens, Birch, Elder, Aſh, and Poplar. Of all theſe, the Fig tree and the Willow bee lighteſt, and therefore fitteſt for that purpoſe. Theſe trees laſt rehearſed, bee good for caskets and foſſers: wicker baskets alſo and prettie paniers, which be made of winding twigs. Their wood beſides is faire and white, ſtreight alſo and eaſie to be graven. The Plane wood is ſoft and gentle, but moiſt withall; and ſo is the Alder. Elme likewiſe, Aſh, Mulberrie, and Cherry-tree wood, is pliable, but drier and more powderous. The Elme, of all kinds of wood, will keepe ſtreight and ſtiffe beſt, and not warpe at all: and becauſe it twineth and caſteth not, it is paſſing good for hinges and hookes, for ſawne bords, for ledges in dores and gates: ſo as this regard bee had of exchange, that the upper end of the bord which grew toward the head of the tree, bee fitted to the nether hinge or hooke of the dore; and contrariwiſe the butt end, ſerve the higher. The Date tree and the Corke, have a ſoft & tender wood: the Apple tree, Peare tree, and Maple, have as ſad and maſſie; but brittle it is, like as all wood that goeth with a croſſe and frizled graine. And looke what tree ſoever is naturally hard

and

A and tough, the wild and the male of the same kind, have their wood more churlish than otherwise it is in the rest. Semblably, those that beare no fruit, are of a faster and firmer wood than the fruitfull: unlesse it bee that the males bee bearers, and the female barren, of which sort are the Cypresse and Cornell trees. The wood of Cypresse, Cedar, Ebene, Lotus, Box, Yewgh, Iuniper, and the Olive both savage and gentle, is never worme-eaten, ne yet rotteth for age. As for all other trees, long it is before these decay, to wit, the Larch, the Oke, the Corke tree, Chestnut and Walnut tree. The Cedar, Cypresse, and Olive wood, never doth chinke or cleave of it selfe, unlesse it be by some accident.

It is commonly thought, that the Boxe, the Ebene, the Cypresse, and Cedar wood, is everla- 4.
sting and will never be done. An evident proofe thereof as touching all these sorts of timber, by
B the judgement and choise of so many men, was to bee seene in that famous temple of *Diana* in Ephesus: for all Asia set to their helping hand and contributed toward that worke, which in four yeares and not before, they brought to an end and finished. The beames, rafters, and spars that went to the making of the roufe, were by the generall voice of the whole world, of Cedar timber. As touching the statue or image it selfe of the goddesse *Diana*, it is not so certainely known of what wood it was: all writers, save onely *Mutianus*, report that it was of Ebene. As for him, a man who had been thrice Consull of Rome, and one of the last who upon their owne sight of the said thing, wrate thereof, avoucheth that it was made of Vine wood; and that, howsoever the temple was ruined and rebuilt againe no lesse than seven times, yet the foresaid image was never altered nor chaunged. Who saith moreover, that *Canetias* chose that wood for the best (for
C so he named the workman that cut and carved it.) And I much marvell thereat, considering that by his saying this image was of greater antiquitie than that of ladie *Minerva*, much more than of prince *Bacchus*. He addeth moreover and saith, that this statue was embaulmed within, by reason of the precious oile of Spikenard, which was distilled into it at many holes: by meanes of which medicinable liquor, the wood was nourished, and the joints held close and fast together: whereat I cannot chuse but marvell againe very much, that considering the statue was so small, it should have any peece or joint at all. Now as touching the leaves of the dores belonging to this temple, they were by his report, of Cypresse wood: and continued still fresh and new to the eie, notwithstanding it is foure hundred yeares well neare since they were made. Where, by the way, this is to be noted, that these dores stood foure yeares glewed in the clave. And verily, this wood
D was chosen for that purpose, because among other properties, the Cypresse alone hath this gift, to looke alwaies shining and polished, and never loseth the glosse and beautie. And for to prove this, we need not to goe farre: Looke but upon the image of * *Vejovis* in the Capitoll, made of Cypresse wood, doth it not endure still faire and trim? and yet was it dedicated and consecrated in that temple, in the yeare after the foundation of Rome, 551. * or, *Jupiter.*

A famous and memorable temple there is of *Apollo* at Vtica, where the beames and maine peeces of timber, made of Numidian Cedars, remain as whole and entire as at the first day when they were set up, which was when the citie was first founded: by which computation, they have continued alreadie 1188 yeares. Moreover, it is said, that at Saguntum a citie of Spaine, there is a temple of *Diana* still standing, a little beneath the citie: and yet as king *Bacchus* mine Authour
E saith, 200 yeares before the ruine & destruction of Troy, the same men which brought the image of the said *Diana* from the Island Zacynthus, founded the temple aboveſaid. For the antiquitie and religion whereof, *Anniball* made some conscience to demolish it, and would not once touch it: and therein are to be seene at this day the beames and rafters of Iuniper, sound and good. But above all other, memorable is the temple of the said goddesse *Diana* in Aulis, which was built many hundred yeares before the Trojane warre: but what kind of timber was emploied about the Carpentrie thereof, is not well knowne. Howbeit, this we may boldly resolve upon, that the more odoriferous any wood is, the more durable also it is, and everlasting.

Next to those trees above rehearsed, the wood of the Mulberrie tree is most commended, which in tract of time as it groweth to be old, waxeth also blacke. Moreover, some kinds of wood
F as they be more lasting than other: so they continue better being emploied in one kind of work, than they doe in another. The Elme timber will well abide the aire and the wind. The wild Oke Robur loveth to stand within the ground, and the common Oke is good in the water: let it bee used above ground to take the aire and the weather, it will cast, warpe, and cleave, too bad. The Larch wood agreeth passing well with water workes, and so doth the black Alder. As for the Oke

Robur,

Robur, it will corrupt and rot in the sea. The Beech will doe well in water, and the Walnut tree likewise: but to stand within the earth, they are principall good, and have no fellow. And for the Iuniper, it will hold the owne, being laid under ground: but for building above in the open aire, it is excellent good. The Beech and the Cerrus wood rot quickly. The small Oke called Esculus cannot abide the water. The Cherrie tree wood is firme and fast: the Elme and the Ash are tough; howbeit, they will soone settle downeward and sag, being charged with any weight, but bend they will before they breake: and in case before they were fallen, they stood a while in the wood, after they had a kerfe round about, for their superfluous moisture to run out untill they were well dried, they would be the better & surer in building. It is commonly said, that the Larch wood if it be put into ships at sea, is subject to the worme: like as all other kinds of wood, unlesse it be the wild and tame Olive. For to conclude, some timber is more readie to corrupt & be marred in the sea, and others againe upon the land.

Chap. xli.

Of wormes that breed in wood.

OF vermine that eat into wood, there bee foure kinds. The first are called in Latine Teredines: a very great head they have for the proportion of the bodie, and with their teeth they gnaw. These are found onely in ships at sea, and indeed properly none other bee Teredines. A second sort there bee, and those are land wormes or mothes, named Tineæ. But a third kind resembling gnats, the Greekes tearme by the name of Thripes. In the fourth place bee the little wormes: whereof some are bred of the putrified humour and corruption in the verie timber: like as others againe engender in trees, of a worme called Cerastes: for having gnawne and eaten so much, that hee hath roume ynough to turne him about within the hole which he first made, hee engendreth this other worme. Now, some wood there is so bitter, that none of these vermine will breed in it, as the Cypresse: others likewise so hard, that they cannot eat into it, as the Boxe. It is a generall opinion, that if the Firre bee barked about the budding times, at such an age of the Moone as hath been before said, it will never putrifie in the water. Reported it is by those that accompanied *Alexander* the great in his voiage into the East, that in the Island Tylos lying within the red sea, there be certain trees which serve for timber to build ships, the which were knowne to continue two hundred yeares: and being drowned in the sea, were found with the wood nothing at all perished. They affirmed moreover, that in the same Island there grew little plants or shrubs, no thicker than would well serve for walking staves to carie in a mans hand, the wood whereof was massie and ponderous, striped also and spotted in manner of a Tygres skin; but so brittle withall, that if it chaunced to fall upon a thing harder than it selfe, it would breake into fitters like glasse.

Chap. xlii.

Of timber good for Architecture and Carpentrie: what wood will serve for this or that worke: and which is the strongest and surest timber for rouses of building.

WEe have here in Italie, wood and timber that will cleave of it selfe. For which cause our Maister Carpenters give order to besmeare them with beasts dung, and so to lie a drying, that the wind and piercing aire should not hurt them. The joists and plankes made of Firre and Larch, are very strong to beare a great weight, although they bee laid in length overthwart. Contrariwise, the rafters made of the wild Oke Robur, and Olive wood, will bend, and yeeld under their load: wheras the other named before, do resist mainly and withstand, neither will they easily breake, unlesse they have much wrong: nay sooner doe they rot, than faile otherwise in strength. The Date-tree wood also is *tough and strong, for it yeeldeth not, but curbeth the contrarie way. The Poplar setleth and bendeth downeward: whereas the Date-tree contrariwise riseth upward archwise. The Pine and the Cypresse are not subject either to rottennesse or worme-eating. The Walnut-tree wood soone bendeth, and is saddle-backt as it lieth, (for thereof also they often use to make beames and rafters) but before that it breaketh, it will give warning by a cracke; which saved many a mans life in the Island Antandros, at what time

*Valida, ex Theophrast.

A time as being within the common baines, they were skared with the cracke that the floore gave, and ran forth ſpeedily, before all fell. Pines, Pitch trees, and Allar, are very good for to make pumps and conduit-pipes to convey water; and for this purpoſe their wood is boared hollow: lying buried under the ground, they will continue many a yeare ſound and good; let them be uncovered without any mould and lie above-ground, they will quickely decay. But if water alſo ſtand above the wood, a wonder it is to ſee how they will harden therewith and endure. Firre or Deale wood, is of all other ſureſt and ſtrongeſt for rouſes above head: the ſame alſo is paſſing good for dore leaves, for bolts and barres: alſo in all ſeelings and wainſcot whatſoever it be, whether Greekiſh, Campaine, or Sicilian, it is the beſt, and maketh very faire worke. A man ſhall ſee the fine ſhavings thereof run alwaies round and winding, like the tendrils of a vine, as the B Ioyner runneth over the painels and quarters with his plainer. Moreover, the timber of it is commendable for coches and chariots. And there is not a wood that maketh a better and ſtronger joynt with glew, than it doth: inſomuch, as the ſound planke will ſooner cleave in any other place, than in the joynt where it was glewed.

Chap. xliii.

Of glewing timber: of rent, cloven, and ſawen painell.

C GReat cunning there is in making ſtrong glew, and in the feat of joyning with it, as well in regard of ſeelings and wainskot made of thin bourd and painell, as of marquetrie & other inlaid workes: and for this purpoſe, Ioyners doe chuſe the miſtreſſe threadie graine that is moſt ſtreight, which ſome call the Fertill veine, becauſe ordinarily it breedeth others; and yee ſhall ſee it braunching and curled, as if it ſhed teares and thoſe trickling downe. In every kind of wood whatſoever, the criſped graine will not take glew and bear a joynt. Some wood it is impoſſible to glew and joyne, with peeces of their owne kind, much leſſe of other wood; as the hard oke Robur. And lightly yee ſhall not have peeces of a divers nature, knit and unite well in a joint, no more than if a man ſhould goe about to glew and joyne ſtone & wood together. The Serviſe tree wood cannot in any wiſe ſort in a joynt with the Corneill wood; no more can the Hornebeame and the Box: after them, the Tillet or Linden wood may hardly away with his ſocietie. To ſpeake generally, whatſoever wood is gentle and apt to bend, (ſuch as we call pliant) the ſame is D good and eaſie to bee wrought to any worke that a man would have: to which, you may put the Myrtle and wild Fig-tree. Durable and handſome withall, either to bee cut, ſquared, cloven, or ſawen, are all thoſe kinds of wood which be by nature moiſt. As for drie peeces of timber, they give not way ſo faſt to the ſaw, as greene: and yet you muſt except the Oke and the Box wood, which although they be greene, doe ſtiffely withſtand the ſaw-gate, choking and filling up their teeth even; by which meanes the ſlit is hindred, and the worke goeth not forward: which is the cauſe alſo that the ſawyers draw up and let downe the ſaw twice, before the teeth ſend from them any duſt into the pit. As for the Aſh, it is moſt eaſie to be wrought, put it to what uſe you will, and maketh the faireſt worke: and namely for horſemens ſtaves, better it is than Hazell, lighter than the Corneil, and more gentle and pliable than the Serviſe wood. The French white Aſh, it will E bend well for cart-thills and fellies. The Elme would be very like vine-wood, but that it is more ponderous and heavie. The Beech is eaſie to bee wrought into any forme, brittle though it be and tender: yet thereof are made fine trenchers, thin ſhindles, and ſuch like, as will wind & bend every way: and therefore it is the only wood commendable for to make pretie caskets, paniers, and boxes. The maſt-Holme alſo may be cut into fine thin foile or leaves like plates, and thoſe alſo are of a daintie and pleaſant colour: but ſingular good is the wood thereof for ſuch things as fret and weare with rubbing, and namely, the axeltrees in wheeles: and as the Holme (I ſay) is fit for this purpoſe in regard of the hard wood; ſo the Aſh likewiſe, becauſe it is ſo lyth and pliable: in which two reſpects, the Elme is choſen before them both. Moreover, the wood of theſe trees before-named, are notable to make many pretie tooles that ſerve artizans in their daily F worke: and therefore it is commonly ſaid, That the wood of the wild Olive, Box, maſt-Holme, Elme, and Aſh, are excellent good for awgre-handles and wimble-ſtocks. Of the ſame alſo are made mallets; but beetle heads of the bigger ſort, of the Pine and Holme. A great reaſon why theſe kinds of wood are the more tough & harder, is when the trees have their right ſeaſon, and be cut downe in their beſt time, rather than too ſoone and before they are come to maturitie.

Thus it hath been knowne that doore-hinges and hookes made of Olive wood (which otherwise is most hard) if they have rested any long time, and not been worne by shutting and opening too and fro, have put forth fresh buds, as if they had growne still in the plant. As for dore-barres and bolts, *Cato* would have them made of Holly, Bay-tree, and Elme. The handles and helves of rusticall tooles, mattocke steles, and spade trees, *Hyginus* willeth they should be either of Horne-beame, Holme, or Cerrus. For fine painell in fret-worke, for seeling also and overlaying other wood, these are the chiefe, the Citron, Terebinth, Maple of all sorts, Boxe, Date tree, Hulver, Holme, Elder root, and the Poplar. The Alder tree likewise (as hath been said) doth affourd certaine swelling bunches and hard knots, which may be cut and cloven into most daintie flakes and pretious leaves, as faire and pleasant to the eye for their damaske braunch, as either Citron or Maple: serting which three aside, there be no knurres and nodosities in any tree worth ought and of account.

Moreover, ye shall have trees ordinarily in the mids toward the heart, carie a more crisped and curled wood; and the nearer it is to the butt or root end, the finer is the graine, more braunching also, and the streakes winding in and out. Loe, from whence first came the superfluous expence to cover and seele one wood with another! See how those trees which for their very wood were of no price, are become more costly and deerer, when they serve as a barke to clad others! that one tree forsooth by this means, should be sold many and sundrie times at a severall price. Thus have been devised (I would not else) thin leaves of wood, like gold or silver-foile. And yet that is not all: for there is come up of late a devise, to paint and die in sundry colours the hornes of beasts, to cut and saw their teeth into thin plates: and whereas at first there was fret-works only inlaid and set out with Ivorie here and there, soone after it came to passe, that the wood was covered all over therewith. Neither hath the royot and wastfull prodigalitie of the world staied there, but proceeded farther, even to search into the deepe sea for that, which might serve in stead of wood and timber. Thus the Tortoise shell hath been cut into flakes and leaves, for want forsooth of wood upon drie land. And now of late daies, certaine monstrous spirits, during the Empire of *Nero*, have found out a devise to disfigure the Tortoise shell also with paintings, that it might be sold the deerer when it lookt like wood. Thus meanes are wrought, that the price of beds should be raised and set up by this means: thus they would have the Terebinth wood to be excessive deere and above the woorth: thus must the Citron wood be enhaunsed to an higher rate: and thus the Maple is counterfeited, Tortoise shels are foisted in the place and bought for it. To conclude, of late daies the curiositie of men was such, that they could not content themselves with rich and costly wood; and now for to beautifie and set out their wood, Tortoise shels must needs be bought, there is no remedie.

Chap. xliii.

The age of trees: what kind of trees they be that are of least continuance. Semblably of Misselto, and the Priests called Druidæ.

IF a man would consider the hidden corners of the world, and the inaccessible desarts that be in it, he might by infallible arguments conclude and resolve, that there be some trees which have continued time out of mind, and lived infinitely. But to speake of their age only that are knowne (even by the testimonie of auncient records, & those faithfully delivered unto us) there are to be seen standing and growing at this day, about Linternum (a town in Campaine) certain Olive trees, which *Scipio Africanus* (the first of that name) planted long since with his own hand. In the same place also there is a Myrtle tree, of a rare and admirable greatnesse; and under it, a cave or hole in the ground, wherein (by report) there lyeth a dragon that keepeth the ghost and soule of the said *Scipio*. And at Rome, in the court-yard belonging to the chappell of goddesse *Diana Lucina*, there is yet to be seene a Lote tree standing before the said chappell, built in the yeare of the Anarchie, what time as Rome stood desolate of all magistrates, and that was 369 yeares after the foundation of the citie: but how much more auncient this tree is than the said temple, God knoweth: for, elder it is without all question, considering that of the grove or tuft of trees there growing, which the Latins call Lucus, the said goddesse *Diana* tooke her name * *Lucina*. Now is it 450 yeares or thereabout, since that time, and so old it is doubtlesse. Another Lote tree there is and elder than that, but the age thereof is likewise uncertein: known it is by

* *Gratia Lucinæ dedit hæc tibi nomina Lucus.* Ovid.

A by the name Capillata, [*i.* hairie:] ſo called, becauſe the haire of the veſtall Nuns heads is uſually thither brought, and there conſecrated. And yet is there a third Lotus at Rome in the court-yard and cloiſter about the temple of *Lucane*, which *Romulus* built for a perpetuall monument and memoriall of a victorie, and defraied the charges out of the tenths of the pillage and ſpoile that hee woon from his enemies; and this tree is at leaſt full as old as the citie of Rome, if it be true that *Maſſurius* writeth. The roots thereof, paſſing along the ſtreet where the Burgeoiſes uſe to keepe their reſidence, doe reach as farre as the ſtately market-place or Hall of *Cæſar*. There grew by it a Cypreſſe tree alſo of the ſame age, the which by an overſight and careleſſe neglect, fell downe no longer ſince than the laſt yeere of *Nero* the Emperour. But why ſtand wee long hereupon? there is an Holme growing in the Vaticane, elder than Rome it ſelfe, with a plate of
B braſſe upon it engraven in Tuſcane letters, containing an inſcription or title: whereby it appeareth, that even in thoſe daies the ſaid tree for antiquitie, was worthie of peoples devotion. Moreover, it is well knowne, that the Tyburtines are more auncient than the Romans, and their citie Tybur founded many a yeare before Rome: and yet certaine it is, that there bee yet three Holmes there remaining alive, elder than *Tyburtus* himſelfe, their firſt founder: upon which trees (as the voice goeth) hee obſerved the flight of birds, and thereby tooke his auſpices and warrant from the gods to build the ſaid citie. And (by report) the ſonne he was of *Amphiaraüs*, who died at Thebes an hundred yeares before the Trojane warre. Writers there be who affirme, that both that Plane tree which groweth before the temple of *Apollo* at Delphos, was ſet by king *Agamemnons* owne hand: as alſo another in the ſacred grove of Caphys in Arcadie. Furthermore,
C at this day, there be trees near unto the ſtreight of Callipolis, ſometime called Helleſpontus, over-againſt the citie of the Ilians, where old Troy ſtood, growing cloſe unto the tombe or ſepulchre of *Proteſilaus*: which every fourteen yeares ſo ſoon as they are ſhot up ſo tall only as they may ſeeme to diſcover and ſee the citie Ilium, immediatly begin to wither and fade; & afterwards ſpring againe and grow anew unto that age and height aforeſaid. Hard by the citie of Ilium, there be certaine Okes alſo (as folke ſay) neare unto the tombe of *Ilus*, which were then planted or ſet of acorns, when Troy began to be called Ilium. It is reported moreover, that the Olive tree remaineth yet alive at Argos, unto which *Argus* tied ladie *Iö*, after ſhee was transformed or turned into an Heifer. About Heraclea in Pontus, there be certaine altars erected to the honour of *Iupiter* ſurnamed *Stratius*, over which there ſtand two Okes, both ſet by the hands of
D *Hercules*. In the very ſame tract there is an haven, ennobled and renowmed by the name of *Amycus* the K. of the Bebrycians there ſlaine. His tomb, from the very day of his ſepulture, hath ben overſhadowed with a Bay tree (planted there and then for that purpoſe) which the people of that countrey doe call The raging or mad Lawrell; for plucke but a braunch or twig thereof be it never ſo ſmall, and carie it into a ſhip, all the mariners & paſſengers within, will fall a brawling, and never agree untill it be caſt out and throwne away out of the veſſell, which was brought thither from the tree aforeſaid. Of a certaine region we have before written, called Aulocrene, lying in the way betweene Apamia and Phrygia; and there the paiſants of that countrey can ſhew you that very Plane tree, on which *Marſyas* the muſician hung himſelfe in a melancholly mood, for that he was overmatched in his owne cunning and profeſſed skill, by *Apollo*: and ſurely like it is,
E that even then he made choiſe of that tree for the bigneſſe. Over and beſides, in the Iſland Delos, there is a Date tree to be ſeen, which hath remained there ever ſince that the ſaid god *Apollo* was borne and reared there. The wild Olive tree at Olympia (whereof *Hercules* ware the firſt coronet or guirland) is kept and tended ſtill with great devotion. The very ſame Olive tree alſo (by folkes ſaying) continueth this day at Athens, which ſprung up at the very time that *Minerva* and *Neptune* ſtrove togither about giving the name to the citie of Athens. And thus much of long-lived trees.

Contrariwiſe, Pomegranat trees, Fig trees, and Apple trees, live a very ſhort time: & of theſe, the haſtie kind or Ienitings, continue nothing ſo long as thoſe that bear and ripen later: neither yet thoſe that carie ſweet fruit, laſt ſo well as they that bring foorth ſower. The Pomegranat tree
F alſo with the more pleaſant fruit, is ſhorter lived than the other. The like is to bee ſaid of Vines, and namely, ſuch as bear greater burden of grapes and yeeld moſt wine. Howbeit *Græcinus* ſaith, That there have been vine trees knowne to live threeſcore years. It ſeemeth alſo, that trees which come up in wateriſh and moiſt places, are not of any long continuance, but ſoone die. In deed Bay trees, Apple trees, and Pomegranat trees, do age & looke old quickly; howbeit, they ſpring

fresh againe from the root. Well then, the Olive trees hold out life and live very long: for after the common opinion and agreement of all writers, they continue ordinarily 200 years. There is a little hill named Carne within the territorie of Tusculum, not far from Rome citie side, clad and beautified with a goodly grove and tuft of Beech trees, so even and round in the head, as if they were curiously kept, cut, and shorne artificially with garden sheares: which grove was consecrated in old time to *Diana*, by the common consent of all Latium, which did their devotions there. In it there was one especiall faire tree above the rest, which *Passienus Crispus*, a man in our daies of great authoritie (as having been twice Consull in his time, and reputed an excellent Oratour, who also afterward mounted to higher place of reputation by marrying *Agrippina* the Empresse, by which match he became father in law to *Nero* the Emperour) cast a fancie and extraordinarie liking unto: insomuch as he was wont not onely to take his repose and lie under it, to sprinkle and cast wine plentifully upon it, but also to clip, embrace, and kisse it otherwhiles. Neare adjoyning as a neighbour to the said grove, there is an Holme, which of it selfe alone is much renowmed: it beareth in compasse about the butt thereof 35 foot, and sendeth out ten monstrous big armes from the bodie, which may goe well enough for as many trees, and those every one so great as it is wonderfull. Surely this one tree alone (a man would say) resembled a whole woood.

Moreover, there is nothing more certaine than this, that Ivie killeth trees. The like is to be said (in some sort) of the Misselto, although it is generally thought, that the harme thereby is not so soon seen. And this you must thinke, that this Misselto is not to be taken for the fruit of a tree, and therefore as great a wonder it is in nature, as any other: for some things there be, that not willing to grow out of the earth, engender in trees; and having no proper place of their own habitation to seat themselves in, sojourne as it were and make their abode with others, and of this nature is the Misselto. Also, in Syria there is a certaine hearbe named *Cadytas, which windeth about, not trees onely, but also very bushes and thornes: likewise, all about the pleasant vale Tempe in Thessalie, you shall have a kind of Ferne called Polypodie, to doe the same: also, the Pulse named Dolychos, which is Fasels or Kidney beanes, and the wild running-laced Thyme, Serpyllum. Semblably, that which the Greeks call Phaunos: the very same, that after a man hath cut and proined the wild Olive, engendreth thereupon. The like is to be said of Hippophestion, which groweth upon the Fullers thorne or thystle: it beareth certaine little heads and hollow knobs with nothing in them, small leaves, and a white root: the juice whereof is singular good to evacuate and purge the bodie, for the diversion of ill humors, in the falling sickneſse. But to returne againe to Misselto, there bee three kinds thereof. For that which groweth on the Firre and Larch tree, is called Stelis in Euboea, and Hyphear in Arcadia. And as for that, which properly is Misselto indeed, most men are of opinion, that it groweth fast to the common Oke, the wild Robur, the Holme, wild Plumtree, and the Terebinth, & not lightly upon any other trees. Howbeit, in greatest plentie it is seene upon the Oke, and that is named Dryos Hyphear. A difference there is in the Hyphear and Misselto, on what tree soever they are found (except the Holme and common Oke) in regard of the savor, which is strong & stinking in the one more than the other. The leafe in them both hath no pleasant smell, and in the Misselto it is bitter, clammie, and viscous besides. Of the twaine, Hyphear yet is the better to feed sheepe and such cattell fat: only at the first it purgeth yll humors, and maketh them to scoure apace, but afterwards it fatteth them; I meane such as were able to beare the said purgation. But in case any of them were deepely tackt and infected with the rot, or other inward consuming disease, they can never endure the taking of the said Hyphear, but they die upon it. The onely fit time for this kind of curing them, by the way of purging, is in Summer, & that for fortie daies space together. There is moreover, by mens saying, another difference in Misselto: for that which groweth upon trees, shedding their leaves in winter, looseth also his owne leaves; but contrariwise, it continueth alwaies greene upon such trees as hold their leaves all the yeare long. Moreover, set or sow this Misselto which way soever you will, it will never take and grow: it commeth onely by the mewting of birds, especially of the Stockdove or Quoist, and the Blackbird, which feed thereupon, and let it passe through their bodie. And this is the nature of it, unlesse it bee mortified, altered and digested in the stomacke and belly of birds, it will never grow. It exceedeth not at any time a cubit in heigth, notwithstanding it be alwaies greene and full of braunches. The male beareth a certaine graine or berry: the female is barrain and fruitlesse. But sometimes neither the one nor the other beareth at all.

* Some take this for *Cassutha*, or *Cuscuta*, *i.* Doder.

Now

A Now as touching Birdlime, it is made of the berries of Miſſelto, gathered in harveſt time before they are ripe; for if they ſhould tarie ſtill to take ſhowres of raine, well might they thrive and encreaſe in bigneſſe, but their ſtrength and vertue would be gone cleane, for ever making any ſuch glew or birdlime aforeſaid. Beeing ſo gathered, as is beforeſaid, they muſt be laid abroad a drying, and when they be once drie, they are braied or ſtamped, and ſo put in water to ſteep, and let to putrifie for the ſpace of twelve daies or thereabout. This one thing yet in the whole world + is the better for putrefaction, and ſerveth to good purpoſe. When this is done, the ſaid berries thus putrified and corrupt, are beaten or punned once againe with mallets, in running water; by which meanes when they are husked and turned out of their skins, the fleſhie ſubſtance within, becommeth glutinous and will ſticke too, in manner of glew. This is the way to make birdlime B for to catch poore birds by their wings, entangled therewith; which fowlers uſe to temper and incorporate with the oile of Walnuts, when they liſt to ſet limetwigs to take foule.

And foraſmuch as wee are entred into a diſcourſe as touching Miſſelto, I cannot overpaſſe one ſtrange thing thereof uſed in Fraunce: The Druidæ (for ſo they call their Divinours, Wiſe men, & the ſtate of their Clergie) eſteeme nothing more ſacred in the world, than Miſſelto, and the tree whereupon it breedeth, ſo it be on Oke. Now this you muſt take by the way, Theſe Prieſts or Clergie men choſe of purpoſe ſuch groves for their divine ſervice, as ſtood only upon Okes; nay they ſolemnize no ſacrifice, nor perform any ſacred ceremonies without branches & leaves thereof, ſo as they may ſeeme well enough to be named thereupon Dryidæ in Greeke, which ſignifieth as much as the Oke-prieſts. Certes, to ſay a truth, whatſoever they find growing upon that C tree over and beſides the owne fruit, be it Miſſelto or any thing elſe, they eſteeme it as a gift ſent from heaven, and a ſure ſigne by which that very god whome they ſerve giveth them to underſtand, that he hath choſen that peculiar tree. And no marveile, for in very deed Miſſelto is paſſing geaſon and hard to be found upon the Oke; but when they meet with it, they gather it very devoutly and with many ceremonies: for firſt & foremoſt, they obſerve principally, that the moon be juſt ſix daies old (for upon that day they begin their moneths and new yeares, yea and their ſeverall ages, which have their revolutions every thirtie yeares) becauſe ſhee is thought then to be of great power and force ſufficient, and is not yet come to her halfe light and the end of her firſt quarter. They call it in their language All-Heale, (for they have an opinion of it, that it cureth all maladies whatſoever) and when they are about to gather it, after they have well and duly pre- D pared their ſacrifices and feſtivall cheare under the ſaid tree, they bring thither two young bullocks milke white, ſuch as never yet drew in yoke at plough or waine, & whoſe heads were then and not before bound, by the horne: which done, the prieſt arraied in a ſurpleſſe or white veſture, climbeth up into the tree, and with a golden hook or bill cutteth it off, and they beneath receive it in a white ſouldiours caſſocke or coat of armes: then fall they to kill the beaſts aforeſaid for ſacrifice, mumbling many oraiſons & praying devoutly, That it would pleaſe God to bleſſe this gift of his to the good and benefit of all thoſe to whome he had vouchſafed to give it. Now this perſuaſion they have of Miſſelto thus gathered, That what living creature ſoever (otherwiſe barraine) doe drinke of it, will preſently become fruitfull therupon: alſo, that it is a ſoveraign countrepoiſon or ſingular remedie againſt all vermine. So vaine and ſuperſtitious are many nations E in the world, and oftentimes in ſuch frivolous and fooliſh things as theſe.

THE XVII. BOOKE OF THE HISTORIE OF NATVRE, WRITTEN BY C. PLINIVS SECVNDVS.

Chap. I.

The wonderfull prices of some trees.

AS touching the nature of all those trees, which of their owne accord doe grow, as well upon the maine land as the sea coasts, we have already treated sufficiently. It remaineth now to discourse of those, which (to speake more truly and properly) are made rather and forced by Art and wit of man, than otherwise come by nature and of themselves. But before I enter into this treatise, I cannot chuse but marveile how it is come to passe, That those trees, which for necessitie & need we having taken from the wild and bruit beasts, and possessed in common with them (considering that men maintaine fight and scramble with them for the fruits that fall, yea and otherwhiles with the foules of the aire, about those which hang upon the tree) should grow to so excessive a price, as to be esteemed among the principall delights and dainties of this world? And that this is so, appeareth by that most notable example (in mine opinion) of *L. Crassus* and *Cn. Domitius Ænobarbus*. This *L. Crassus* (a right renowmed Oratour of Rome as any one of his time) had a stately and sumptuous dwelling upon mount Palatine: howbeit that house of *Q. Catulus* (who defeated in battaile the Cimbrians togither with *C. Marius*) went beyond it a faire deale in magnificense; and stood likewise within the pourprise of the same mount. But the goodliest and fairest pallace known in that age, was that of *C. Aquilius* a gentleman or knight of Rome, situate upon the hill of Osiers, called Viminalis: in regard whereof, there went a greater name of him, than for all the skill hee had in the civile Law, which was his profession. Yet of all those three, *Crassus* only was challenged and reproched for that foresaid house of his. And in this manner is the storie delivered: *Crassus* and *Domitius* (great personages both, and descended from most noble houses in Rome) after they had been Consuls, happened also to be chosen Censors together: and this fell out to be in the yeare after the foundation of the cittie 662: but during this magistracie of theirs, there passed many a foule day and bitter fit between them; so dissonant were their natures, & their conditions so farre unlike. Now it fortuned upon a time, that *Cn. Domitius* (as he was a hot and hastie man by nature, & carried an inward hatred besides in his heart, which soon is kindled & set on fire, yea & most insatiable, upon emulation & envie between concurrents, such as they two were) reproved *Crassus* very sharply for his excesse in expence, & namely, that any Censor of Rome should dwell in so stately and sumptuous a palace as he did; and ever and anon made offer to buy the house, and pay him downright for it *100 millions of Sesterces: whereat *Crassus* (being a man quicke of spirit, of a prompt and present wit, finely conceited withall, and not to seeke for a readie answer) tooke him at his word and accepted of the offer; reserving onely sixe trees that grew about his house. Tush quoth *Domitius*, replying againe, take those trees away, and take all; if they be gone, I will none of the house though I might have it for a single denier. Then *Crassus*, having gotten the vantage and start of him, rejoyned & came upon him thus: Tell me now, I pray you, good *Domitius*, whether of us twaine giveth a scandalous example to the world? whether am I my selfe (I say) offensive, and deserve to be taxed & noted by mine owne Censorship, who can be content to live quietly & lovingly among my neighbours in mine owne house, and that house which came to me by way of inheritance from my father;

* *Millies Sestertium.* An incredible price for a dwelling house: & therfore as *Budæus* thinketh, this place must be corrected, by conference with *Val. Max.* who for (*millies*) hath (*sexagies*) which amounteth little more thã to the 20 part of the other summe.

A father; or you rather, that for ſix trees bid 100 millions of Seſterces? Now, if a man bee deſirous to know, what theſe trees might be? truly they were no other but ſixe Lote-trees, very faire and beautifull indeed, but there was nothing in them commendable, ſave only their ſpreading & caſting a goodly ſhade. And verily, *Cæcina Largus*, a Nobleman & principall citizen of Rome, uſed many a time and often (I remember well) to ſhew me when I was a young man, thoſe trees about his houſe. And ſince our ſpeech hath been of ſuch trees as live very long, theſe I wote well, continued for the ſpace of 180 yeares after *Craſſus* death, unto the great fire that *Nero* cauſed to bee made for to burne Rome; freſh and greene they were with good keeping, and looked young ſtill, like to have lived many a faire day more, had not that Prince haſtened the untimely death even of trees alſo [as well as of cittizens.] Now leaſt any man ſhould thinke, that all the ſumptuoſitie of
B *Craſſus* conſiſted onely in thoſe trees, and that the furniture otherwiſe of his houſe was but mean and ſimple, and could miniſter unto *Domitius* no matter of ſuch conteſting and reproofe, diſpoſed as he was to quarrell and find fault: Know he thus much, That the ſaid *Craſſus* had before that time ſet up in the open hall of that houſe, foure goodly pillars of Hymettian Marble; which in the yeare of his Ædileſhip were brought abroad to enrich and beautifie the Theatre, the Stage and Shew-place of the ſolemne plaies by him ſet out: for as yet there had not been in publicke place at Rome any marble pillar ſeene. Loe how lately is come up this exceſſive expence in rich and glorious building, ſo common in theſe daies. See (I ſay) how in thoſe times, faire trees beautified pallaces more than any thing elſe; inſomuch, as *Domitius* for the want of ſix trees onely, would not ſtand to the price that himſelfe firſt made, no not to buy his very enemie out of houſe
C and home with it. But no marvell if trees were accounted of ſo highly, ſeeing that our anceſtors in old time thought not ſcorne to take otherwhiles their ſurnames from them. Thus that brave and valiant ſouldiour came to be named *Fronditius*, who (maugre the beard of *Anniball*) ſwum over the river Vulturnus, with a chaplet of greene leaves (anſwereable to his name) ſet upon his head, and performed many feats of armes and worthie exploits againſt him. Thus they of the noble *Licinian* familie had for their addition *Stolons* (that is to ſay, the unprofitable waterſhoots that put forth from the root or tree it ſelfe, and never prove or come to any good.) And why ſo? For that one of the ſaid houſe deviſed the meanes to cleanſe trees and vines of ſuch ſuperfluous twigs (the practiſe and feat of cutting which away, is called Pampinatio) and thereupon was one *Licinius* firſt ſurnamed *Stolo*. Moreover, our predeceſſors in auncient time made good ſtatutes
D and ordinances for the maintenance of trees: and expreſſely provided it was by the lawes of the twelve Tables at Rome, in theſe words, *That whoſoever made wilfull waſt, and cut downe any trees growing in another mans ground, ſhould be peined in the court for a treſpaſſe done; and forfeit for every ſuch tree, five and twentie pound of braſſe money*. But what ſhould we thinke of this? Did thoſe lawmakers, trow yee, ſuppoſe or imagine that other wild trees would ever have growne to that high reckoning abovenamed, and which now they are come unto, who valued fruitfull trees at no greater price, & ſet the penaltie for the treſpaſſe, ſo low? But never marvell we any more hereat, conſidering to what a proportion Apple-trees and ſuch like are riſen unto. For there bee many of them here about the citie of Rome, in the villages near adjoining, which are ſet for a yearly rent of two thouſand Seſterces; and one of them yeeldeth more profit and revenue by the year to the
E owner, than a pretie ferme in times paſt of good domaine, to the landlord. Hereupon came the invention of grafting trees: for this purpoſe have wee ſuch baſtard fruits entermingled one with another, of ſundrie kinds; as if Apples and other fruits were not for poore men to eat, but grew onely for the rich. Hence forward now therefore will we ſhew the right, perfite, and abſolute manner how to order and cheriſh them, that it may appeare by what meanes eſpecially, ſuch annuall commoditie can bee made of them, as is beforeſaid. For the better performance of which diſcourſe, I meane to leave the common and ordinarie way; neither will I handle the uſuall and vulgar manner of that point in husbandrie, wherein every man is perfect, and whereof no man maketh queſtion: but deliver ſuch matters onely, as be uncertaine and doubtfull, whereby oftentimes folke are deceived and beguiled. For, to breake my head or buſie my braines in needleſſe
F trifles, and therein to affect a kind of curioſitie, was never my manner yet, nor is it any part of my meaning and intention now. But before I doe enter into particulars, my purpoſe is to treat in generalitie of this matter, and touch breefely the conſideration of heaven and earth both, ſo farre forth as may concerne in common all kinds of trees whatſoever.

CHAP.

Chap. II.

Of the nature of the Skie respective unto trees: and what quarter thereof they should regard.

TRees generally doe like best that stand to the Northeast wind: for it nourisheth them well, causeth them to spread thicke and grow every way in length and breadth; and withall maketh the timber more fast and strong. But in this rule most men doe erre, and be much deceived: for in underpropping Vines, the forkes would not bee set opposite against that wind to hinder the blast thereof; a point that is to be observed in regard of the North wind onely. Moreover, wee find by experience, that if trees have a kindly winter and cold season in their due time, their wood will be more firme, and so likewise will they bud and shoot out best: otherwise, if the warme Southerne winds blow upon them much, yee shall have the trees prove soft and feeble, and their blossomes come to nothing, blouming as they doe before time. For if it chaunce, that presently after their flowers be fully out and readie to shed, there fall any store of raine, the fruit is quite gone for that yeare. And as for Almond trees and Peare trees, if it be but close and cloudie weather onely, without any raine, or the wine stand South when they flower, sure they bee to loose their fruit. Certes, a glut of raine in May, at what time as the Brood-hen star called Virgiliæ doth arise, is exceeding hurtfull to Vines and Olive trees: for then is the very season of their knitting or conception. Then bee the foure decretorie or criticall daies, that give the dome of Olive trees, either to good or bad: this is the Southerly point of filthie, foule, and glowmie weather, whereof wee have spoken before. Moreover, all manner of graine feeleth the inconvenience of Southerne wind at the time of their ripening. Well may corne make haste and ripen sooner, but it shall never have the kind maturitie and perfection as it ought. As for the cold pinching black frosts and Northerne winds, which blow out of season, come they early or come they late, they be hurtfull all. But if the wind stand Northeast in winter, there is nothing so good generally for all fruits of the earth. And verily, a good shower now and then during that time, will do no harm; and that men wish for raine then, the reason is evident: for why? trees with bearing of fruit, are drawne drie and have lost their naturall moisture, with shedding their leaves they bee poore and feeble; so that it is kind for them to be hungrie then, and to have a greedie appetite to new food, which is raine. Now if the winter be open and warme withall, that so soone as the trees have done bearing, they rest not betweene, but conceive againe presently upon it (that is to say, bud & spurt anew, yea, and fall afresh to blossome, whereby they have another evacuation that way also, to spend their sap and radicall moisture) we find by experience, that there is nothing in the world so bad for them. Nay, if many such yeares come together, immediately one after another, the verie trees themselves will die; for who can looke for better, when they are thus pined and famished? He then *whosoever he was that said, Husbandmen were to wish for faire winters: surely hee was no friend therein to trees, nor never praied for them: neither are wet midsummers good for Vines. But in truth, That winter dust should cause plentifull harvest, was a word spoken in a braverie, and proceeding from a pregnant wit and jollie spirit: For otherwise, who knoweth not, that every man (wishing well to trees and corne indifferently) praieth, That snow might lie long upon the ground? The reason is, for that not only it keepeth in and encloseth the vitall breath & soule (if I may so say) of the earth, readie to exhale out and vanish away, yea, and driveth it back again into the blade and root of corne, redoubling therby the force and vigor thereof: but also because it both yeeldeth liquour and moisture thereunto gently by little and little, and the same withall fine, pure, and passing light: considering, that snow is nothing else but the fome or froth of raine-water from heaven. This humor therefore, not falling forcibly all at once to drowne the root, ne yet washing away the earth from it (but distilling drop-meale a little at once, in that proportion and measure as thirst requireth and calleth for it) nourisheth all things, as from a teat or pap; nourisheth (I say) and neither drencheth nor overfloweth them. The earth also for her part, by this meanes well soaked, swelleth and hooveth as it were with a leaven, and lieth thereby more light and mellow: thus being full of juice and moisture it selfe, & not barren, but well replenished with seeds sowne, and plants suckled, thus continually in her womb; when the open time of the spring is once come to discharge her, she sheweth her selfe fresh and gay, and willingly entertaineth the warme weather of that season.

*Virgil.

By

A By this meanes eſpecially, we ſee how corne liketh well upon the ground, and thriveth apace every where, unleſſe it be in climates where the aire is alwaies hote, as in Ægypt. For continuance and ordinarie cuſtome alone effecteth the ſame there, which the ſeaſon of the time, & moderate temperature of the aire elſewhere. And in one word, bee the place whatſoever, paſſing good it is to keepe away the thing that is hurtfull. For in the moſt parts of the world it happeneth, That when either corne is winter-prowd, or other plants put forth and bud too earely, by reaſon of the mild and warme aire; if there follow any cold weather upon it, all is nipped, blaſted, and burnt away. Which is the cauſe, that late winters doe harme unto the wild trees alſo in the forreſt. The more paine and ſorrow likewiſe ſuch trees abide, by reaſon of their owne thick branches ſhading one another, and not eaſily admitting the warme Sunne; and deſtitute they are be-
B ſides of mans helping hand to cure them: for growing as they doe in wild and deſart forreſts, impoſſible it is to lap and wrap them about with wreaths and thumb-ropes of ſtraw, and ſo to cheriſh and defend them when they bee yong and tender. Well then, to conclude this matter, Winter raine principally is ſeaſonable and good for all plants: and next to it the dewes and ſhowers that fall immediately before their ſprouting time. A third ſort alſo there be of ſhowers that come when fruits hang on the tree, and are in their growth, yet not too ſoone, namely, before they bee ſtrong and able to abide ſome hardneſſe.

As touching trees which be late-ward and keepe their fruit long ere they ripen, ſuch alſo as require ſtore of nouriſhment and more food ſtill, as namely, the Vine, the Olive, and Pomgranat trees; it is good for them to be watered with raine in the latter end of the yeare. And to ſay a truth,
C every kind of tree requireth a ſeverall raine by it ſelfe, in due ſeaſon, for that ſome ripen their fruit at one time, and ſome at another: ſo as a man ſhall ſee ordinarily the ſelfeſame ſhowers, to hurt one ſort, and to helpe another: yea, and that diverſe effect is to be ſeene in trees and fruits of the ſame kind, as for example, in Pyrries: for the late-ward of them call for raine at one time, and the haſtie or forward at another, and yet indifferently all doe require alike the ſeaſonable ſhowers of Winter, as alſo thoſe before budding time. In which regard, the winds Northeaſt are better than the Southerne, and ſuch Winters be moſt kindly. Semblably, by the ſame reaſon the Mediterranean or mid-land parts of any countrey are for this purpoſe preferred before the maritime or ſea-coaſts (as being for the moſt part colder:) the high and hillie regions before the plains and valleies: and laſt of all, the night raines are held to be more profitable than thoſe that fall by day
D time: for lands new ſowne, and any young plants, enjoy more benefite by ſuch ſhowers in the night, for that the Sunne commeth not ſo preſently upon them againe to drie and drinke up all the moiſture.

Hereunto ought to be annexed the conſideration of Vine-yards, Hort-yards, and Groves, as touching their ſituation, and namely, what part of the heaven they ſhould regard. *Virgill* condemned altogether the planting of any trees, reſpective to the Weſt: ſome have choſen that quarter before the Eaſt. And this have I obſerved, that in moſt mens opinion, the South is beſt. But if I ſhould ſpeake what is mine owne conceit indeed, there can no generall and infallible rule be given concerning this point, for to hold alwaies. All our skill and art herein muſt bee directed by the nature of the ſoile, the diſpoſition of the climate and temperature of the aire. In Affricke,
E although it be nothing profitable for Vine-yards to be planted ſo as they looke into the South, yet kind it is and wholeſome for the Vine-planter and husbandman, by reaſon that all Affricke lieth under the Meridionall or South climate. And therefore he that ſhall ſet Vines there, either into the Weſt or North (howſoever *Virgill* alloweth not of the Weſt) ſhall make an excellent medley betweene the temperature of that aire and the nature of ſoile together. As for the North no man ſeemeth to make any doubt or queſtion, but that Vines ſo planted, will proove right well. And verily, there are not found any Vines to proſper, or to beare more fruit in all Italie, than in that tract which lieth on this ſide, and under the Alps: and there for the moſt part the Vineyards are ſo planted.

Moreover, in this caſe the winds would be much conſidered: for in Languedoc or the province
F of Narbone, in Liguria and part of Tuſcane, they are reputed unskilfull husbandmen that plant any Vine-yards directly upon the Northweſt wind: but it is counted contrariwiſe a ſpeciall point of providence and good husbandrie, to caſt it ſo, as the ſaid wind may flanke it on the ſide. For this is the wind, which in thoſe quarters qualifieth and tempereth the exceſſive heat of the Summer: howbeit, many times, ſo violent and bluſterous hee is, that hee beareth downe before him

the

the roofe of many a houſe, and carieth it cleane away.

Chap. iii.

The ſocietie of the skie and aire with the earth, reſpective to trees.

SOme men doe force the skie for to be obedient and conformable to the earth: as namely, when planting in drie grounds, they have regard to the Eaſt and North: and contrariwiſe, when in moiſt places they reſpect the South. Moreover, it falleth out, that they bee driven otherwhiles to follow the nature of the very Vines, and thereby to bee ruled: whereupon, in cold ground they plant ſuch as be of the haſtie kind, and ſoone ripen their grapes; to the end that they may come to their maturitie and perfection, before cold weather comes. As for ſuch Vines and trees bearing fruit, as cannot abide dewes, thoſe they ſet into the Eaſt, that the Sunne may ſoone diſpatch and conſume the ſaid dew: but looke what trees doe love dewes, and like well therewith, thoſe they will bee ſure to plant againſt the Weſt, or at leaſtwiſe toward the North, to the end they may enjoy the full benefite thereof. All others againe (grounding in manner upon naturall reaſon onely) have given counſell to ſet as well Vines as Trees, into the Northeaſt. And *Democritus* verily is of this mind, that ſuch fruits will be more pleaſant and odoriferous.

Chap. iiii.

The qualitie of ſundrie regions.

AS touching the proper ſeat of the Northeaſt wind, and of all other winds, wee have ſpoken alreadie in the ſecond booke: and our purpoſe is in the next following, to treat of the riſing and falling of ſigns and notable ſtars, of other Aſtronomicall points alſo concerning heaven. Now in the mean time for this preſent, it is ſufficient, that in the former rule of the North wind, wee ſeeme to reſt and reſolve upon the apparent and evident argument of the wholeſome and healthfull climate of the heaven: for as much as we ſee, that evermore all ſuch trees as ſtand into the South, ſooneſt ſhed their leaves. The ſame reaſon alſo is to bee given of thoſe that grow upon the ſea-coaſts: and albeit in ſome places the winds blowing from thence, and the very aire of the ſea be hurtfull, yet in moſt parts the ſame are good and profitable. Certaine plants and trees there are, which take pleaſure to be remote from the ſea, and joy to have the ſight of it only a farre off: ſet them neerer to the vapours and exhalations aſcending from thence, they will take harme and miſlike therewith. The like is to be ſaid of great rivers, lakes, and ſtanding pooles. As for thoſe which we have ſpoken of, they either burn their fruit with ſuch miſts, or refreſh & coole ſuch as be hote with their ſhade, yea, and take joy and proſper in the froſt and cold. And therfore to conclude this point, the ſureſt way is, to beleeve and truſt upon experience. Thus much for this preſent, concerning the Heaven: our next diſcourſe ſhall be of the Earth and Soile, the conſideration whereof is no leſſe difficult to be handled than the other.

Firſt and formoſt, all grounds are not alike good for trees and moſt kinds of corne. For neither the blacke mould (ſuch as Campaine ſtandeth much upon) is in all places beſt for Vines; or that which fumeth and ſendeth up ſmall and thin miſts: neither is the red veine of earth any better, howſoever there bee many that commend it. The white earth or chalkie marle, the clay alſo within the territorie of Alba and Pompeij, for a vineyard, are generally preferred before all other countries (although they bee exceeding fat, which in that caſe is otherwiſe uſually rejected.) On the other ſide, the white ſand about *Ticinum: likewiſe, the black mould or grit, in many places, as alſo the red ſandie ground, although it be well mingled and tempered with fat earth, are all of them nothing to the purpoſe for encreaſe and fruitfulneſſe. And herein muſt men take heed, becauſe oftentimes their judgement may faile when it goeth but by the eie: for we muſt not ſtreight waies conclude, that the ground is rich and battle, whereon we ſee goodly faire and tall trees to grow, unleſſe it be for thoſe trees onely: for where ſhall we meet with any, higher than the Firre? and is there a tree againe that poſſibly can live where it doth? No more is ranke graſſe & plentifull forrage a true token alwaies of a good ground: for there is no better paſture nor grafting to be found than in Almaine; and yet dig but up the greene ſourd and the thinneſt coat of turfe that may be, ye ſhall preſently come to barren ſand under it. Ne yet is it by & by a moiſt ground, that hath upon it deepe graſſe and hearbes ſhooting up in height: no more verily, than a fat

*i. Pavie.

and

A and rich ſoile is knowne by ſticking to ones fingers; as appeareth plainely in all ſorts of clay. And verily, no earth doth fill up the trenches even againe, out of which it was caſt, that therby a man might find out whether the ground bee ſad, or hollow: and generally all ſorts thereof will cauſe yron to ruſt that ſhall be put into it. Moreover, there is no weighing of earth in ballance, to know by that meanes which is lighter or heavier: for who could poſſibly ever ſet downe the juſt weight that earth ſhould have? Againe, the ground that is caſt up into bankes by the overflow of great rivers, is not alwaies commendable: ſeeing that ſome plants there be that decay, if they be ſet in water. And ſay that ſome ſuch banke were ground good ynough, yet it continueth not ſo long; unleſſe it be for Willowes and Oiſiers onely. But if you would know a rich ground indeed, one of the beſt arguments and ſignes thereof is this, when you ſee it to bring forth a thick and ſtrong
B haulme or ſtraw, ſuch as uſually groweth in that noble territorie Laborine within Campaine; which is of that bigneſſe, that the people of the countrey uſe it for fewell in ſteed of wood. Now, this ground, ſo good as it is, where and whenſoever we have found it, is hard ynough to be tilled, and requireth great labour and husbandrie, putting the poore husbandman to more paines in manner with that goodneſſe of it, than poſſibly hee could have with any defects and imperfections thereof. For even the hote earth, called by the name of Carbunculus, which uſeth to burne the corne ſowne thereupon, may be helped & remedied (as it is thought) by ſetting it with plants of poore and hungrie Vines. The rough gravell ſtone which naturally will crumble as grit, many writers there be that allow and commend, for Vines. As for *Virgil*, he findeth no fault with the ground that beareth ferne and brake, for a Vineyard. The earth that is brackiſh, and ſtandeth
C much upon ſaltpetre, is thought to be more ſound for many plants than others; and in regard of vermine that uſe to breed therein, much ſafer alſo. Neither do high bankes and hils remaine untilled and naked for want of good husbandrie, if ſo be a man have the caſt of it, to eare and break them up skilfully. As for the plaines, they are not all of them expoſed to the Sunne or ſubject to the wind more than need requireth. And to ſpeake of froſts, miſts and fogs, there be Vines (as we have ſaid alreadie) which are nouriſhed and fed with them. And to conclude, hereby wee may ſee, that in every thing there is ſome one deepe ſecret or other, wherein it behoveth each man to employ his ſpirit and ſet his mind for to ſearch them throughly and find them out. What ſhall wee ſay then to this, That oftentimes thoſe things which have been approoved by long experience and many obſervations, become otherwiſe, and chaunge their uſuall manner? In Theſſalie
D about Lariſſa, the whole region, by reaſon of a lake that was let out and drained drie, prooved much colder: and the Olives which there grew before, left bearing and died all, upon it. In like ſort, neare unto Ænos, the Vines were all ſcorched and burnt, by occaſion, that the courſe of the river Ebrus was brought neare unto them, an accident that beforetime never befell unto them. Semblably, about the citie Philippi, the whole countrey being made drie by ſluces and trenches artificiall; altered withall the whole diſpoſition of the aire and weather, and chaunged the verie habite of the heaven above their heads. But in the territorie of Syracuſa, the forraine Coloners that thither came to inhabite and practiſe husbandrie, by ridding the ground from all the ſtones, marred all the corne in the countrey; ſo mirie and durtie it was by that meanes, untill ſuch time as they were driven to lay the ſtones againe where they had them. In Syria, the husbandmen goe
E lightly over with their plough, and take no deepe ſtitch in making their furrowes, for feare of the ſtonie rocke lying ebbe under the good ground, which in Summer ſeaſon would burne all their graine and ſeed ſowne there. Now, there be certaine parts of the world, where a man ſhall ſee one and the ſame effect to proceed both of extreame heat, and alſo of exceſſive cold. Thracia is exceeding cold, and thereby plentifull in corne. Affricke and Ægypt be as hote, and yet come not after it for fertilitie in that kind. In Chalcia, an Iſland belonging to the Rhodians, there is one place above the reſt ſo fruitfull, that the Barley which was ſowed in the due time and ſeaſon of the yeare, they mow once, and preſently put it into the ground againe; which will be readie to be cut downe the ſecond time, with other corne in harveſt. In the Venafrane tract within the realme of Naples, the gravellie ground is thought meeteſt for Olive trees, and therin they bear moſt plen-
F tifully: contrariwiſe, about Bœtica in Spaine, the fatteſt ſoile is beſt for that purpoſe. The excellent grape that maketh the good Punicke wine, ripeneth ſoone upon the very rockes: but the Cæcube Vines ſtand ſoaked and drenched (as it were) in the mariſh low grounds of Pomptinum. See what a difference and diverſitie there is in cauſes, to make this varietie in ſundrie plots of ground! *Cæſar Vopiſcus* being convented before the Cenſors, and there pleading his cauſe, affirmed

med openly, that the plaines of Rosea were the very fat of Italie, and resembled the kell or leafe of a fed and franked swine: wherein (quoth hee) if a man left forkes or props to day, they will bee overgrowne and covered with grasse by to morrow. But surely, this ground is good for nothing but pasture. Yet notwithstanding, Nature would have us still to learne and grow skilfull every day more than other: and for that intent shee hath laid open the defects and imperfections of the ground, even there, whereas the commodities therof be neither so certain, nor so well known. And therefore let us in the first place speake of those faults for which the earth is blamed.

Chap. V.

Sundrie sorts of earth.

IF a man would know which is a leane, hungrie, bitter ground, there is no better experiment and proofe thereof, than by the blackish, misliking, and unkind hearbes growing thereupon: like as, when they come up scorched and burnt, they shew a cold soile: also, when they seeme illfavoured and unpleasant to the eie, the earth no doubt is soaked and drowned in wet. As for red sandie ground and cley, you need goe no farther than to your owne eiesight. And such soiles as these be, is of all other, hardest to bee wrought and tilled; they so clog and load both the harrow teeth and the plow-shares, with huge & heavie clods. Howbeit, the ground that is thus churlish to be eared and husbanded, is not alwaies bad and naught for encrease. But it fareth cleane contrarie with the pale and wan ashie earth, as also with the white sandie soile: for the barraine ground is soone found by a thicke and callous crust that it hath, even at the first dent of culter, or stroke of mattocke.

Cato setteth downe breefely, as his manner is, all the defects & faults of ground in these words: *Take heed* (quoth he) *of a rotten ground, and see that you sturre it neither with cart, nor touch it with beast.* What should wee thinke was his meaning by this tearme of his, that he should feare rotten ground so much, as to forbid in a manner to tread and goe thereupon? Let us call to mind the rottennesse that is in wood: and thereby shall we find those faults that he abhorreth and detesteth so much in earth. In good faith, by rotten earth hee understandeth drie, spungeous, and full of holes, rugged, hoarie, eaten, old, and hollow. So as in that one significant word (*Cariosa*) he said more than could be expressed possibly by any multiplicitie of language whatsoever. For if a man would rip up to the quicke the imperfections that are in grounds, he should find, that some peeces there be of it that may be tearmed truly old and overworne, not for any age (for who can say properly, that earth is subject to old age) but by reason of their naturall defects: in regard whereof, a ground may be weake, feeble, barren, and no longer good for to bring forth any thing. The same *Cato* judgeth, That ground to be principall which lieth at the foot of an hill, and runneth forth in manner of a plaine, into the South, which is the very situation of all Italie: and by a blackish and swart earth, which he calleth [*Pulla*] he meaneth a gentle, tender, & mellow soile. And this we will determine to be the best simply both for worke or tillage, and also for gaine and encrease. Now let us (if yee please) stand a little upon this word *Tenara*, [*i.* Tender] which he useth in this sence: you shall find a marvellous signification thereof: and that hee implieth thereby, as much as your heart can wish to be in a ground. That is it, which is so temperate in fertilitie, that is it which to bee wrought is so gentle, soft, pliable, and mellow; neither wet, nor yet drie and thirstie. Now doth this ground shine againe after the plough-share, resembling that veine of earth, which *Homer*, the very fountaine and spring of all good wits, reported to have beene engraven by a * god, in the armour [of *Achilles*:] adding moreover, that the said earth looked blacke withall: wherein he observed a wonderfull peece of workmanship, notwithstanding it was wrought in gold. This is that ground, I say, which being new broken and turned up with the plough, the shrewd and busie birds seeke after, and goe under the plough-share for it: this is it, that the verie Ravens follow the ploughman hard at heeles for, yea, and are readie for greedinesse to pecke and job under his verie feet. And here, in this place I cannot chuse but relate the opinion that is currant among our roiotous and delicate gallants: with some other thing also making for our purpose, in the discourse of this argument which wee have in hand. Certes *Cicero*, a man reputed (as hee was no lesse indeed) for a second light of all good learning and literature, Better are esteemed (quoth hee) the sweet compositions and ointments which tast of earth, than of saffron: where note by the way, that this great clerke chose to use the word

*Vulcane,

of

A of taſt rather than of ſmell, in ſuch odoriferous perfumes and mixtures. Well, to ſpeake at a word, ſurely that ground is beſt of all other, which hath an aromaticall ſmell and taſt with it. Now if we liſt moreover to be better inſtructed, what kind of ſavour and odour that ſhould be, which we would ſo gladly find in the earth; we may oftentimes meet with that ſent, even when ſhe is not ſtirred with the plough, but lieth ſtill and quiet, namely, a little before the ſun-ſetting, eſpecially where a rainbow ſeemeth to ſettle & pitch her tips in the Horizon: alſo, when after ſome long and continuall drought, it beginneth to raine; for then being wet and drenched therewith, the earth will ſend up a vapour and exhalation (conceived from the ſunne) ſo heavenly and divine, as no perfume (how pleaſant ſoever it be) is comparable unto it. This ſmell there muſt be in it when you ere it up with the plough: which if a man find once, he may be aſſured it is a right
B good ground; for this rule never faileth: ſo as (to ſay a truth) it is the very ſmell and nothing els, that will judge beſt of the earth: and ſuch commonly are new broken grounds, where old woods were lately ſtocked up: for all men by a generall conſent, doe commend ſuch for excellent. Moreover, the ſame ground for bearing is held to be farre better, whenſoever it hath reſted between, and either lien ley or fallow; whereas for vineyards it is cleane contrarie: and therefore the more care and diligence is to be emploied in chuſing ſuch ground, leaſt wee approove and verifie their opinion, who ſay, That the ſoile of all Italie is alreadie out of heart and wearie with bearing fruit. This is certaine, that both there and elſewhere, the conſtitution of the aire and weather, both giveth and taketh away the opportunitie of good husbandrie, that a man cannot otherwhiles doe what he would: for ſome kind of grounds there is ſo fat and readie to reſolve in-
C to mire and dirt, that it is impoſſible to plough them and make good worke, after a ſhowre of raine. Contrariwiſe, in Byzacium a territorie of Affricke, it is farre otherwiſe: for there is not a better and more fruitfull peece of ground lieth without dore than it is, yeelding ordinarily 150 fold; let the ſeaſon be dry, the ſtrongeſt teeme of oxen that is, cannot plough it: fall there once a good ground ſhowre, one poore aſſe, with the helpe of a ſillie old woman drawing the plough-ſhare at another ſide, will be able to goe round away with it, as I my ſelfe have ſeene many a time and often. And whereas ſome great husbands there be, that teach us to enrich and mend one ground with another, to wit, by ſpreading fat earth upon a leane and hungrie ſoile; and likewiſe by caſting drie, light, and thirſtie mould, upon that which is moiſt and over-fat; it is a meere follie and waſtfull expence both of time and travaile: for what fruit can he ever looke to reape
D from ſuch a mingle mangle of ground?

Chap. VI.

Of the earth which Britaine and Fraunce love ſo well.

THe Britaines and Frenchmen have deviſed another meanes to manure their ground, by a kind of lime ſtone or clay, which they call Marga, [*i.* Marle.] And verily they have a great opinion of the ſame, that it mightily enricheth it & maketh it more plentifull. This marle is a certaine fat of the ground, much like unto the glandulous kernels growing in the bodies of beaſts, and it is thickned in manner of marow or the kernell of fat about it.

E

Chap. VII.

The diſcourſe of theſe matters continued according to the Greekes.

THe Greekes alſo have not overpaſſed this in ſilence: for what is it that they have not medled withall? The white clay or earth wherewith they uſe to marle their grounds in the territorie of Megara, thoſe onely I meane which are moiſt and cold, they call Leucargillæ. Theſe marles (all the kind of them) do greatly enrich Fraunce and Britaine both, and therefore it would not be amiſſe to ſpeake of them more exactly. In old time there were two ſorts thereof, and no more: but of late daies (as mens wits are inventive every day of one thing or other) they
F have begun to find out more kinds, and to uſe the ſame: for there are now divers marles, the white, the red, the columbine, the clay ſoile, the ſtonie, and the ſandie: and all theſe are but two in nature, to wit, either hard and churliſh, or elſe gentle and fat. The triall of both, is knowne by the handling, and a twofold uſe they yeeld; either to beare corne onely, or elſe for graſſe and paſture alſo. The ſtonie or gravelly ſoile is good onely for to nouriſh corne; which if it be white

withall, and the pit thereof found among springs or fountaines, it will cause the ground to be infinite fruitfull; but it is rough in handling, and if it be laid too thicke upon the lands or leyes, it will burne the verie ground. The next to it is the red marle, called also Capnumargos, which hath intermingled in it a certaine small stonie grit full of sand: This stonie marle the manner is to breake and bruise upon the very lands; and for the first yeares, hardly can the straw be mowne or cut downe for the said stones. Lighter is this marle than the rest by the one halfe, and therefore the cariage thereof into the field is least chargeable. It ought to be spred and laid thin, and some thinke that it standeth somewhat upon salt. But both the one and the other will serve well for fiftie yeares, and the ground enriched thereby, will (during that time) yeeld plentie as well of corne as grasse.

Chap. viii.

Sundrie sorts of Earth and Marle.

OF those marles which are found to be fat, the white is chiefe; and thereof be many sorts. The most mordant and sharpest of them all, is that whereof we spake before. A second kind there is of chalkish clay, which our goldsmiths use [called Tripela:] this lieth a great depth within the earth, insomuch as many times men are driven to sinke pits an hundred foot deepe, for it; and those have a small and narrow mouth above, but within-forth and under the ground, they be digged wider, by reason that the vaine thereof runneth many waies, in manner of other mettall mines. This is the marle so much used in Britaine: the strength thereof beeing cast upon a land, will last fourscore yeeres; and never yet was the man known that herewith marled the same ground twice in all his life time. The third kind of white marle, is that which the Greekes call Glischromargon: it is no other than the Fullers chalkie clay mixed with a viscous and fattie earth. The nature of it, is to breed grasse better than to beare corne: for after one crop of corne is taken off the ground in harvest, before seed time is come for winter grain, the grasse will be so high growne, that a man may cut it down and have a plentifull after-math for hay: and yet all the while that it hath corne upon it, you shall not see it to beare any grasse besides. This marle continueth good thirtie years: if it be laid over-thicke upon a land, it choketh the ground in manner of * Cumine. The Columbine marle, the Gaules call in their language, by a name borrowed of the Greekes, Pelias, [*i.* Dove or Pigeon marle:] it is fetched out of the ground in clots and lumps, like as stones bee hewed out of quarries: with sunne and the frost togither, it will resolve and cleave into most thin slates or flakes. This marle is as good for corne as for herbage. As for sandie marle, it will serve the turne for want of other: yea & if the ground be cold, moist, and weely, the husbandman will make choise thereof before other.

* *Cymini. Turneb.* readeth *Signini*, & meaneth thereby shards of potters work and such like rubbish.

The Vbians, upon my knowledge, use to enrich their ground and make it more battle (though their territorie otherwise be most fertile) with any earth whatsoever; provided alwaies that it be digged up three foot deepe at least, and laid a foot thicke; a devise that no other countrey doth practise: howbeit this soile and manner of manuring, continueth good not above ten yeares. The Heduans and Pictones, have forced their grounds and made them most plentifull, with limestone: which is found also by experience to be passing profitable for vines and Olives.

To come now to the ordering of this peece of husbandry. The ground ought to be ploughed first, before marle of any sort bee cast upon it; to the end that the medicinable vertue and substance thereof, might the sooner and more greedily be received into it. Now forasmuch as marle is at the first over-rough and hard, not so free in the beginning as to resolve and turne into blade or grasse, it had need of some compost or dung to be mingled with it: for otherwise, be it never so rich, it will rather doe harme than good to the ground, by reason that it is yet straunge and not acquainted therewith: and yet helpe it this way as well as you can, it will not bring foorth any plentie the first yeare after it is laid on. Last of all, it skilleth much to consider the nature of the ground, which you meane to marle: for the drie marle, forteth well with a moist soile; and the fattie, hitteth that which is drie and leane. But when the ground is of a middle temperature between both, it mattereth not whether you use the white goldsmiths chalke, or the Columbine marle, for either of them will serve well enough.

Chap. ix.

The use of ashes upon lands: of Dung: what graine or pulse sowne, doth make the ground more plentifull, and what burneth it.

THe people dwelling beyond the Po, make such account of ashes for to enrich their grounds withall, that they prefer it before horse-muck, and such like: which dung (because they take it to be verie light) they burne also into ashes for that purpose. Howbeit (as we have said before) in one and the same corne-land, they use not ashes and mucke both at once: no more doe they cast ashes in hortyards for to nourish young trees; nor in fields, for some kind of corne. Some are of judgement, that grapes are fed with dust: who also doe cast dust upon them when they begin to bloome, yea and bestrew dust upon the roots as well of vines as other trees. Certaine it is, that in the province of Narbon they use so to doe; and they are assuredly perswaded, that grapes ripen better and the vintage commeth the sooner thereby: because in those parts dust doth more good than the Sunne.

As for mucke, there be divers sorts thereof, and in old time much use there was of it: for in *Homer* we read, that long ago the good old king [*Laertes*] was found laying soile and dung upon his land with his owne hands. The first that devised mucking of grounds, was (by report) *Augeas*, a king in Greece: but *Hercules* divulged the practise thereof among the Italians, who in regard of that invention immortalized their king *Stercutius* the sonne of *Faunus*. *M. Varro* esteemeth the dung of Blackbirds (gathered out of their bartons where they bee kept in mew) above all others. He highly magnifieth and extolleth it also, for that it bringeth forth so good forage to feed kine, oxen, and swine withall: avouching for certaine, that they will become fat beefe and porke with no meat sooner. Wee must thinke well therefore and hope the best of the world now adaies, since that our auncestors and forefathers so long ago had so great bartons and pens, that the dung of foules there kept, was sufficient to helpe their hard and hungrie grounds. In the second degree of goodnesse, *Columella* raungeth Pigeons dung gathered out of dovecotes: the third place hee giveth to that of Hens, and other land pullen, rejecting altogither the dung of water-foule. Howbeit all other authours (setting these two aside) attribute with one voice and consent unto the excrements of mans bodie, the greatest praise for this purpose. Some of them prefer mans urine, and namely when the haires of beast-hides have been soked therewith and quicke-lime togither in the Tanners pits. Others use urine alone by it selfe, only they mingle water with it againe, but in greater quantitie a good deale, than they (whose urine it was) did put to the wine when they dranke it: and good reason too; for more need there is now to correct and represse the malice thereof, considering that besides the native malignitie of the wine it selfe, mans bodie hath given and imprinted into it, a strong and unsavorie qualitie. Thus you may see how men labour, strive, and trie conclusions, to feed and enrich the very ground, the best way they can devise. Next unto the ordure and urine of mans bodie, the filthie dung of swine is most commended: only *Columella* condemneth it. Some praise the mucke of any four-footed beasts whatsoever, so they were fed with Tree-trifolie, called Cytisus. Others preferre the dung of Pigeons before any other; in the second place that of Goats; thirdly of sheepe; then of kine and oxen; and lastly of cart-jades, mules, asses, and such like. Thus you see as well what difference there was in times past, betweene this dung and that; as also what were the rules (so farre as I can gesse and learne) whereby they went, in the use and ordering thereof: for, to say a truth, the old way is best, even herein as well as in other matters. Over and besides, the practise hath been alreadie seene in some of our provinces (where there is so great store of cattaile bred) to riddle and sift their dung over their ground through sieves, in manner of meale; and so in processe of time it looseth not only the stinking sent and ill-favoured sight that it had, but also turneth into a pleasant smell, and looketh lovely withall. Of late, found it hath been by experience, that Olive trees doe like and prosper very well, if the ashes of lime-kills especially bee laid to their roots. *Varro*, among many other precepts, addeth and saith, That corne grounds would bee manured with horse dung, because it is the lightest; but medowes require compost that is heavier, and namely, made by beasts that have barley for their provender; for that such soile bringeth plentie of grasse. Some there be also, that prefer the dung made by horses, before the mucke of kine and oxen; likewise sheeps treddles, before goats dung; but asses mucke before all other, because they

they eat and chew their meat most leisurely. But daily experience teacheth the contrarie, and testifieth against the one and the other. And thus much as touching compost of mucke.

Furthermore, all men are of opinion, that nothing is better for the ground, than to sow Lupines therupon; provided alwaies, that before it cod, it be turned into the ground by the plough, spade, or two-piked yron forke: also when it is cut downe, to make it into wads or bottles, and so to burie them at the roots of trees, and vines especially. In countries where there are no cattell to better the lands, it is thought good to manure the same in stead of beasts dung, with verie hawme, straw, and ferne. *Cato* hath a devise to make an artificiall mucke or compost of litter, lupine straw, chaffe, beane stalkes, leaves and braunches both of mast-Holme and Oke. Hee saith moreover to the same purpose: Weed out of the standing corne, * Walwort [otherwise called Danewort] and Hemlocke; also from about osier-plots, plucke up rancke weeds, or ground-Elder; also Reeke or Sea-grasse, and dead leaves or braunches lying rotten under trees: when thou hast so done, strew and lay a course of them under sheepe where they be folded. *Item*, If thy vine begine to decay and wax leane, burne the shreads and cuttings of the owne, and turn the ashes under ground hard to the roots thereof. *Item*, Where thou meanest to sow any wheat or such like bread-corne, draw thy sheepe thither, and there fold them. He saith moreover, that the sowing of some graine is as good as a dunging to the ground: for these be his very words, The fruit it selfe of the earth is a batling to the earth, and namely, Lupines, Beanes, and Vetches, for they mucke the lands: like as on the contrarie side, Chiches doe burn the ground, both because they are plucked, and also for that they stand upon salt. Semblably doth Barley, Fœnigreeke, Ervile, and generally all kind of pulse which are pulled and not mowen down. *Item*, Take heed (quoth *Cato*) that you set no pepins or kernels, where you meane to sow corne. As for *Virgil*, he is of opinion, that the sowing of Line-seed for flax, likewise of Otes and Poppies, do burn corne-ground and pill it out of heart. He also giveth rules as touching mucke-hills, That they should be made in the open aire, within some hollow place where it may gather water; that they bee covered over with straw and litter, for feare they should drie in the sunne; and last of all, that they have a good strong stake of Oke pitched and driven in about the mids thereof, for so there will no snakes nor such like serpents breed and engender therein. Moreover, as touching the spreading of mucke, and mingling it with the mould of a land, it is exceeding good to do it when the wind setteth full West, so that the Moone then be past the full and in the waine. But this rule many have mistaken and not construed aright, supposing that they should so doe when the Westerne wind Favonius beginneth to rise, and namely in the moneth of Februarie only: whereas indeed most corne lands require this point of husbandrie in other moneths as well. But looke what time soever you list to doe it, be sure in any hand that the wind doe then blow from the Æquinoctiall point of the West, and that the moone then be in the waine, and drie withall. Have regard to these rules and observations, you will wonder to see the effects thereof, and what encrease the earth thereby will yeeld.

* *Herba Allen.*

Chap. x.

The planting and setting of trees: the manner how trees doe grow, by a Sion slived and plucked from the root.

NOw that we have alreadie sufficiently treated of the considerations as well of the aire and skie, as of the earth, belonging unto plants and trees; me thinkes it were to good purpose to discourse of the industrie and artificiall means that men have used to make trees grow: and verily we shall find no fewer kinds of them that come by mans hand, than of such as Nature it selfe hath brought forth; so kind and thankfull have we been to her, as to make recompence in this behalfe. First and foremost therefore this is to be noted, That all trees doe grow either of seed sowen, or of braunches growing to the tree and couched in the ground, or of an old stocke from whence new imps may sprout: also, either of a slip or sprig plucked from another tree, and so laid in the ground; or of a young shoot, twig, impe, or Sion, engraffed in the very trunke of a tree, slit and cloven for that purpose. For I cannot chuse but marveile much at *Trogus*, who was verily perswaded, That about Babylon the leaves onely of Date trees being set or sowen, would proove trees. Now whereas there bee so many devises aboveсaid for to nourish trees, this you must understand, that some trees there be which will grow by many of these waies before specified,

A fied, and others by them all. And verily the moſt part of this knowledge hath been taught by Nature her ſelfe: for firſt of all, we have learned by her for to ſow ſeed, by occaſion that we have ſeen ſome to fall from trees, which being received by the ground, have chitted, taken root, and lived. And in very truth, ſome trees there be that grow no otherwiſe, as Cheſtnut and Walnut-trees, excepting only thoſe that being cut downe, doe ſpring new againe from the root. Of ſeed alſo (although the ſame be farre unlike to others) thoſe alſo will grow; which are uſually planted otherwiſe, as for example, Vines, Apple trees, and Pyrries: for in theſe the ſtone and pepin within, ſerveth in ſtead of the ſeed; and not the fruit it ſelfe, as in thoſe before rehearſed, the kernels whereof [*i.* the fruit] are ſowne. Medlars likewiſe may come up of ſeed. But all the ſort of theſe that ſpring after this manner, be late ere they come forward, and ſlow in growth: they turne alſo
B to a degenerate and baſtard nature, & had need to be graffed anew ere they be reſtored to their owne kind: which is the caſe of Cheſtnuts alſo otherwhiles. Howbeit there be others for them againe, which (ſow or ſet them what way you will) never grow out of their owne kind, and ſuch be Cypreſſes, Date trees, and Lawrels: for the Lawrell commeth up by ſowing, by ſetting, and planting, after ſundrie ſorts. The divers kinds whereof, we have deſcribed alreadie. Of all which, the Lawrell Auguſta with the broad leaves, the common Bay tree alſo that beareth berries, as alſo the wild kind named Tinus, bee ordered all three after one and the ſame ſort. The manner whereof is this: The bayes or beries thereof, bee gathered drie in the moneth of Ianuarie when the Northeaſt wind bloweth: they are laid abroad thin to wither, one apart from another, & not in heaps, for feare they ſhould catch a heat. This done, ſome put them afterwards in dung; and
C being thus prepared and readie for to bee ſowne, they ſteepe them in wine. Others take and lay them within a large basket or twiggen panier, trample them under their feet in a brooke of running water, untill they be pilled and rid of their outward skins: for otherwiſe their skinne is of ſo tough and moiſt a ſubſtance, that it would hardly or not at all ſuffer them to come up and grow. After all this, in a plot of ground well and throughly digged once or twice over, a trench or furrow muſt be made a handfull deepe, and therein the berries ought to be buried by heaps, to wit, twentie or thereabout togither in one place: and all this would be done in the month of March. Lawrels alſo will grow, if their braunches or boughs be bended from the ſtocke and laid within the ground: but the Triumphall Lawrell will come up no other way but by ſetting a graffe or impe cut from it. As for the Myrtle, all the ſorts therof within Campaine, come of beries ſowne:
D but wee at Rome uſe to interre onely the boughs of the Tarentine Myrtle, growing ſtill to the bodie, and by that meanes come to have Myrtle trees. *Democritus* ſheweth another deviſe alſo to encreaſe Myrtles, namely, to take the faireſt and biggeſt beries thereof, and lightly to bruiſe or bray them in a mortar, ſo that the graines or kernels within be not broken; and then to beſmere with the batter or ſtamped ſubſtance thereof, a courſe cord made of Spart or Spaniſh broome, or els hempen hurds, and ſo lay it along within the ground. Thus there will ſpring therof, a marveilous thick hay or wall (as it were) of yong Myrtles: out of which, the ſmall twigs you may draw which way you will, yea and plant them elſewhere. After the like manner, folke uſe to ſow thorns or brambles for to make hedges and mounds, namely, by anointing ſuch another hempen rope with bramble blacke-berries, and interring the ſame. As for Bayes thus ſowen, when they come
E once to beare a darke and blackiſh leafe: Myrtles alſo, when their leaves bee of a wine colour, to wit, of a deepe red (which commonly happeneth when they be three yeers old) it will be time to remoove and tranſplant.

Among thoſe plants and trees that are ſowen of ſeeds, *Mago* maketh much ado, and is foully troubled about thoſe trees that beare nuts, & ſuch like fruit in ſhels: For to begin with Almonds firſt, he would have them to be ſet in a ſoft clay ground that lieth into the South: and yet he ſaith againe, that Almond trees love a hot and hard ſoile; for in a fat or moiſt ground, they will either die or els wax unfruitfull. But above all, he giveth a rule to chuſe Almonds for to ſet or ſow, that be moſt hooked, and eſpecially ſuch as were gathered from a young tree: alſo he ordaineth, that they ſhould be well ſoked or infuſed in ſoft beaſt ſhearne or thin dung, for three daies togither: or
F at leaſtwiſe in honyed water, a day before they be put into the ground. *Item*, They ought (by his ſaying) to be ſet charily with the ſharpe and pointed end pitched downward, and the edge of the one ſide to turne into the Northeaſt. Alſo that they muſt ſtand three and three togither in a triangle, forſooth, ſo as there be a handbreadth juſt between every one. Moreover, that every tenth day they ought to be watered, untill they bee ſhot up to a good bigneſſe. Now to come unto

Walnuts, they be laid along within the earth, with this regard, that they do lye upon their joints. G
As for Pine-nuts, there would be sixe or seven of their kernels put togither into pots that have holes in them, and so buried in the ground: or els they should bee ordered after the manner of the Bay tree, which commeth of berries bruised, as hath been shewed before.

The Citron tree will grow of seed, and may be set also of sprigs or twigs drawn to the ground from the tree, and so couched. Sorvise trees come of the graines thereof sowed of a quicke-set plant also with the root, or of a slip plucked from it. But as the Citron trees live in hot grounds, so these Sorvises love cold and moist.

As concerning seminaries and nource-gardens, Nature hath shewed us the reason and manner thereof, by certain trees that put forth at the root a thicke spring of young shoots or sions; but lightly the mother that beareth these imps, killeth them when she hath done, with her shade H
and dropping togither. And this is evident to be seene in Lawrels, Pomegranate trees, Planes, Cherrie trees, and Plum trees: for standing as these impes doe, a number of them without all order under their mother stocke, they be over-shadowed and kept down so, that they mislike and never come to proofe. Howbeit some few there bee of this sort, that are not so unkind to their yong breed, as to kill them with the shadow of their boughs; and namely, Elmes and Date trees. This would be observed by the way, that no trees have such young imps springing at their feet, but they only, whose roots for love of the warme sunne and moist rain, spread aloft and lie ebbe within the ground. Moreover, the manner is not to set these young plants presently in the place where they must remaine and continue for altogither, but first they are to be bestowed in a peece of ground where they may take nourishment, to wit, in some nource-garden for the nones, un- I
till they be growne to a good stature; and then they are to be removed a second time unto their due place. And a woonder it is to see, how this transplanting doth mitigate even the savage nature of the wildest trees that are: whether it be that trees as well as men, are desirous of novelties, and love to bee travailing for chaunge; or that as they goe from a place, they leave behind them their malicious qualitie, and beeing used to the hand, become tame and gentle like the wild beasts; especially when such young plants are plucked and taken up with the quicke root. We have learned of Nature also, another kind of planting much like to this: for we see that not only water-shoots springing out of the root, but other sprigs slipped from the stocke, live and doe full well: But in the practise of this feat, they ought to be pulled away with a colts-foot of their owne, so as they take a quicke parcell also of their mothers bodie with them, in manner of K
a fringe or border hanging thereto. After this manner they use to set Pomegranat, Filberd, Hazell, Apple, and Servise trees; Medlars also, Ashes, and Fig trees; but Vines especially: mary a Quince ordered and planted in that sort, will degenerat and grow to a bastard kind. From hence came the invention, to set into the ground young sprigs or twigs, cut off from the tree. This was at first practised with foot-sets for a prick-hedge, namely, by pitching downe into the earth, Elder, Quince-cuttings, and brambles; but afterwards men began to do the like by those trees that are more set by, and nourished for other purposes, as namely Poplars, Alders, and the Willow, which of all others may be pricked into the ground with any end of the cutting or sprig downeward, it makes no matter whether, for the smaller end will take as well as the bigger. Now all the sort of these, are bestowed and ranged in order at the first hand, even as a man would have them, L
and where he list to see them grow, neither need they any remooving or transplantation at all. But before we proceed any further, to other sorts of planting trees, it were good to declare the manner how to order seminaries, seed-plots, or nource-gardens.

For to make a good pepinnier or nource-garden, there would be chosen a principall & speciall peece of ground: for oftentimes it falleth out, yea and meet it is, that the nource which giveth sucke should be more tender over the infant, than the owne naturall mother that bare it. In the first place therfore, let it be a sound and drie ground, howbeit furnished with a good and succulent elementall moisture, and the same broken up and after well digged over & over with mattocke and spade, and brought to temper and order, so as it be nothing coy but readie to receive all manner of plants that shall come, and to entertaine them as welcome guests; and withall, as like M
as may be to that ground unto which they must be remooved at last. But before all things, this would be looked unto, that it be rid cleane of all stones; surely fenced also and paled about, for to keepe out cocks and hens and all pullen: it must not bee full of chinkes and cranies, for feare that the heat of the sunne enter in and burne up the small filaments or strings and beard of the

A new roots: and last of all, these pepins or kernils, ought to stand a foot and a halfe asunder: for in case they meet together and touch one another, besides other faults & inconveniences, they will be subject to wormes: and therefore, I say, there would be some distance betweene, that the ground about them may be often harrowed and raked, to kill the vermine, and the weeds plucked up by the heels that doth breed them. Moreover, it would not be forgotten, to proine these yong plants when they are but new come up: to cut away, I say, the superfluous sprigs underneath, and use them betimes to the hooke. *Cato* giveth counsell to sticke forkes about their beds a mans height, and lay hurdles over them, so as the Sunne may be let in underneath: and those hurdles to cover and thatch over with straw or haulme, for to keep out the cold in winter. Thus are yong plants of Peare trees and Apple tres nourished: thus Pine nut trees, thus Cypresses which likeB wise come up of seed, are cherished.

As for the graines or seeds of the Cypresse tree, they bee exceeding small, and so small indeed, that some of them can scarce bee discerned well by the eie: wherein the admirable worke of Nature would bee considered, to wit, that of so little seeds there should grow so great and mightie trees, considering how far bigger are the cornes of Wheat and Barley (to make no reckoning nor speech of Beanes) in comparison of them. What should wee say to Peare trees and Apple trees? what proportion or likenesse is there betweene them, and the prettie little pepins whereof they take their beginning? Marvell we not, that of so slender and small things at the first, they should grow so hard, as to checke and turne againe the very edge of axe and hatchet? that frames and stockes of presses should bee made thereof, so tough and strong, as will not shrinke C under the heaviest poise and weights that be? that Mast-poles comming thereof should be able to beare saile in wind and weather? and finally, that they should affourd those huge and mightie rams, and such like engines of batterie, sufficient to commaund towers and bastils, yea, and beat downe strong walls of stone before them? Loe, what the force of Nature is! see how powerfull she is in her workes! But it passeth and exceedeth all the rest, that the very gum and liquour distilling out of a tree, should bring forth new plants of the same kind: as we will more at large declare in time and place convenient. To returne then againe to the female Cypresse (for the male as hath been said alreadie, bringeth forth no fruit) after that the little bals or pils (which bee the fruit thereof) be gathered, they are laid in the Sunne to drie, during those months, which we have before shewed: and being thus dried, they will breake and cleave in sunder. Now, when they are D thus opened, they yeeld forth a seed, which Pismires are very greedie of. Where another wonder of Nature offereth it selfe unto us, That so small a creature as it, should eat and consume the seed that giveth life and being to so great and tall trees, as the Cypresse. Well, when the said seed is gotten, and the plot of ground laid even and smooth, with cylinders or rollers, it must be sowne of a good thicknesse in the moneth of Aprill: and fresh mould sifted and strewed over with riddles, an inch thicke and no more: for if this graine be buried over deepe and surcharged, it is not able to breake through against the weight of the earth, but in steed of rising up, the new chit turneth and bendeth backward under the ground. And hereupon it is, that folke forbeare either to goe at all upon it, or else they tread very lightly. Being thus sowed, it must be gently watered for three daies following, after the Sunnes setting, (that the earth may drinke equally in all places) E untill the sprouts appeare above ground. Now, after they have had a yeares growth, they be translated, and replanted againe in rewes: for by that time they are come to a span or nine inches in height: but great care must bee had, that the time bee temperate, that is to say, that the weather be fresh and faire, and without any wind. Certes, a wonderfull thing it is to be spoken, That all the daunger or securitie of this tree, standeth upon the choise of that onely day, wherein it is replanted: for let there fall never so small a raine or deaw, nay, let the wind blow never so little, it is a great hazard that it will die. For ever after it is warished and safe ynough, howbeit, they cannot abide a glut of raine, at any time following. Moreover, as touching Injubes, they are likewise set of their graines, in the moneth of Aprill. But that kind of Peaches or Abricots which bee called Tuberes, love better to bee graffed either upon a skeg or wild Plum-stocke, or Quince, or else F upon the wild Hart-Rhamme, called Calabricum, [or Spina Cervina.] To knit up this discourse, the fruit Sebesten and the Servises may be graffed and planted both upon the same kind of stocke: and looke what will beare the one, is apt to receive the other.

CHAP.

Chap. xi.

The manner of translating and replanting, out of one seminarie or nource-garden unto another. How Elmes are to be planted. Also, as touching trenches.

SOme would have us to remoove plants out of one seminarie into another, before they bee set indeed where they should be for to continue: which mee thinkes is a matter of more toile and curiositie than necessitie, howsoever they make promise, That by such transplanting, the leaves will prove larger and broader.

Now for Elmes, their seed or graine is to be gathered about the *Calends of March, when it beginneth to turne yellow, and before the leaves break forth. After it hath been dried in the shaddow for two daies, it is to bee sowne thicke in a plot of ground well broken up and laid hollow beforehand, and then must there be mould serced over through a fine riddle, to the same thicknesse as we have appointed for the Cypresse. In case no raine doe fall in due time, it ought to be watered by hand. After one yeare, the plants that come hereof, must be taken up out of the trenches and raunges wherein they came up, and translated directly into the Elme plots, where they are to grow; with this care and good regard, that they stand a foot at least everie way distant one from another. As for the male Elmes, unto which Vines are wedded, because they are without seed, it is better they were planted in the Autumne: and for that they want seed, they would bee set of plants. Here with us about Rome side, they use to replant them againe in their grove plots, when they be five yeares old, or, as some would have it, so soone as they bee come to twentie foot in height. The manner whereof is this, in a trench or ditch called *Novenarius, three foot deepe in the ground, and as many broad, or rather more, they are set: which done, for three foot in height every way about the foot of each tree from the ground as it standeth, there must be banks raised of some earth, after the manner of those seats which they call Arulæ in Campanie. As for the spaces between tree and tree, they ought to be set out and disposed according to the nature and situation of the place, and as the ground will give leave. In the champion and plaine countrey, those would bee planted that are of a drier nature, and likewise in a thinner course. As for Ashes and Poplars, because they make hast to spring, leafe, and bud out betimes, it is meet that their plants likewise were set and ranged with the first, that is to say, about the *Ides of Februarie; for they also grow of plants, and may well be replanted.

Now for the order of setting trees either in groves, hortyards, or vineyards, we ought to follow the usuall manner of checquer row, called Quincuntiall, which is not so common, but it is also as necessarie: not onely good to admit all kinds of wind to passe betweene, but also faire and pleasant to the eie, considering, that which way soever a man lookes, there offer to his sight both the allies, and rewes, directly raunged in order.

The Opiets or Wich-hazels are sowne of seed after the same manner as Elmes: in like sort also they to bee remooved and transplanted out of their nource-plots, as if they were wild, drawne from the very forrests.

Moreover, above all things this would be considered, that a tree to be removed, ought to bee translated either into the like ground from whence it came, or else into a better. For we must take heed how we do remove plants out of warme grounds, & where the fruit is earely ripe, into others that be colder or late in ripening. Semblably, out of cold and hard places, they would not bee translated into warme, mellow, and forward. *Item*, If it be possible, let the trenches bee cast and digged so long before, that a good thicke greene sourd be overgrowne against the time that you meane to plant. *Mago* is of opinion, That the said ditches or trenches should stand made a year before at the least, that they might be fully seasoned with the Sunne, and receive all raine, wind, and weather, throughly. But in case it fall out otherwise that the opportunitie therof be overslipt, or our leisure will not serve, he would have fires to be made in the middest of them two moneths before, and in no case any trees to be set but after showers of raine. And if the ground be tough or hard, and standing upon the cley, the ditches ought (according to *Mago*) for to bee three cubites deepe every way: and if they be for to plant Plum-trees, hee would have them bee a handbreadth more or a span in deapth, and digged on every side hollow, and vaulted in manner of a furnace, with a narrower mouth in the top. In a blacke veine of ground, by his direction, it is sufficient that they be two cubites and a handbreadth or span deepe, and made foure square in manner

*i. The first of March.

*Nine foot distant every way from another: for trees were planted ordinarily, with that space betweene: as may appeare in the next chapter.

*i. The 13 day of Februarie.

A ner of a quadrangle. In the meaſure and proportion of theſe ditches, the Greeke writers doe accord in one, ſaying, that they ought not to bee more than two foot and a halfe deepe, nor wider than two foot bare: alſo, that in no place it muſt bee under a foot and a halfe deepe; for that in a moiſt ſoile, we ſhall come ordinarily neare to water about that skantlin, and not before. But *Cato* is of another judgement, If (quoth he) the place be wateriſh, let the trenches be three foot broad in the mouth, but in the bottome not above a foot and a hand-breadth, but ſee they bee foure foot deepe: provided alwaies, that they be* paved beneath with ſtone: and for want thereof, laid with greene willow baſtons, and for default of them, with vine cuttings, or ſuch trouſſe; ſo that they lie halfe a foot thicke. But conſidering the nature of trees whereof we have before written, I thinke it not amiſſe to adde ſomewhat of mine owne, namely, The more ebbe that any roots of
B trees creepe under the ground, the deeper they muſt be ſet into the earth, as for example, the Aſh and the Olive tree: for they and ſuch other like ought to ſtand foure foot deepe. As for all the reſt, it skils not, if they goe no deeper than three foot, for that is thought ſufficient. [Stocke me up this root here (quoth *Papyrius Curſor* a Roman Generall, in a braverie, when he meant to terrifie the Pretor of the Prænestines.) Wherby it is plain, that the more ſecure and ſafe way in his judgement, was rather to cut the ſtocke and maiſter Root indeed, than ſlightly to pare away thoſe bare roots that appeare naked above ground; for that mought be done, and the tree never the worſe for it.] Some there be that would have round pebble ſtones laid in the bottome of ſuch ditches, which might as well containe & keepe water, as let it forth and give iſſue thereto: whereas broad flat ſtones would not ſo doe, but beſides, hinder the root that it ſhould not goe downe
C and take hold of the earth. For to keepe therefore a meane betweene, it were good in mine opinion, to lay gravell under the root.

*It ſeemeth that *Cato* meant of trenches to draine water out of low grounds: and not as *Plinie* miſtaketh.

Moreover, there be diverſe men of this mind, that a tree ſhould not be removed, either under two yeares old, or above three: whereas others make no queſtion to tranſplant them after the firſt yeare, without more adoe. *Cato* alloweth not of tranſlating a tree, unleſſe it bear in thickneſſe more than five fingers. And verily, ſo exactly hath he written hereof, that he would not have forgotten, to marke in the barke of trees the South ſide, before they were taken up, in caſe, hee had thought that it was materiall to the replanting of them, that they ſhould ſtand juſt in the ſame poſition and accuſtomed coaſt of the heaven, as they did before; for feare leaſt that ſide which regarded the North, if now it ſhould bee oppoſed againſt the South, might cleave and rift with
D the heat of the Sunne, not uſed thereto: and contrariwiſe, the parts which looked Southward, might now by the Northerne winds, be clunged and congealed withall. Now, there bee ſome that affect a cleane contrarie courſe, and namely, in the Fig tree and the Vine; exchaunging the one ſide for the other: being fully perſuaded, that by that meanes they will beare leaves thicker, preſerve and defend their fruit better, and in the end ſhed fewer: more particularly, that the Fig-tree thereby will be the *more eaſie to climbe. Moſt men take great heed of this only, that when they prune trees, and cut off the top ends of boughs, the cut may be toward the South; without any regard or conſideration, that in ſo doing they expoſe the boughs to the daunger of cleaving, by reaſon of the hote Southerne wind, which lieth unceſſantly beating upon them. Yet hold I rather with them, that would have braunches cut Southeaſt or Southweſt, namely, toward the points
E where the Sunne is, at the fift and eight houres of the day. Another ſecret there is beſides, wherof they are as ignorant, howbeit, not to bee neglected, namely, to beware that the roots of ſuch trees as are to bee replanted, ſtay not long above ground, and thereby waxe drie: alſo, that trees be not digged up, either ſtanding into the North, or in any quarter betweene that point and the Southeaſt, where the Sunne riſeth in midwinter, in caſe the wind ſit in thoſe corners: or at leaſtwiſe, that the roots be not expoſed bare againſt any of thoſe winds: for ſurely, many a tree dieth hereby, and husbandmen never know the cauſe thereof. *Cato* utterly condemneth all manner of winds whatſoever, yea, and raine too, all the while that trees bee in remooving. Moreover, in this caſe it is ſingular good, that there hang to the roots of theſe trees when they bee tranſlated, as much of the old earth wherin they lived and grew before, as may be, yea, and (if it were poſſible)
F to bring them away with the turfes whole and entire, lapped faſt about the roots. And therefore *Cato* provided well, that ſuch yong plants ſhould be caried in baskets, earth and all together with the roots. Doubtleſſe, not without very great reaſon there is one Author ſaith, That it is ſufficient that the uppermoſt courſe of the old mould which lay at the foot of the tree, ſhould bee put under the root thereof now when it is replanted. Some write, that if the bottome of the hole or

Scanſilem, reading it ὑβάτερον, haply: for ὑβλαστότερον out of *Theophraſtus*, i. more fertile and fruitfull.

grave

grave be paved with stone where Pomgranate trees should stand, the Apples or fruit that they G
beare, well never burst nor cleave upon the trees. Also, that the roots of trees when they are to be set, should be laid bending at one side, and not stand direct and streight. Moreover, that the tree in any case bee set just in the middest of the ditch or hole made for it. It is said moreover, that if a man plant a Fig tree, together with the sea-onion, Scilla (which is a kind of the Bulbi) it will make hast to beare Figs, and those will not be subject to the worme: and yet other fruits will be worm-eaten nevertheless, set them with the said Scilla as well as you can. As for the roots of a tree, who maketh any doubt, that great care should be had in the taking of them up? so as they might seeme rather drawne forth gently, and not plucked up violently. But my purpose is not to dwell in these matters, nor to stand much upon such points, which have a manifest reason, and whereof no man is ignorant or doubtfull; to wit, that the earth is to bee well driven and beaten downe H
close with a rammer, that it may lie fast about the roots, which *Cato* judgeth to bee a principall point for to bee observed in this businesse: who also giveth a rule, that the place where a tree is cut in the bodie, should be plaistered over with dung, covered over also, and fast tied with leaves.

Chap. xii.

Of the spaces and distances that ought to be betweene trees planted: of their shaddowes and droppings: of the place where they should be planted.

IT belongeth to this place properly for to speake of the distances betweene tree and tree, in the setting. Some writers are of opinion, That Pomgranat trees, Myrtle trees, and Lawrels, should I
be planted thicker than ordinarie, howbeit, with this regard, that they be set nine foot asunder one from another. As for Apple trees, they may stand a little more at large, Peare trees somewhat wider than they, Almond trees and Fig trees yet a little more than all the rest. But herein must we be ruled and directed by the boughs spreading more or lesse, by the rowme of the place it selfe, and according to the shaddow that each tree casteth. There is not (I say) any one of these considerations to bee neglected, and the shade especially of all others would bee observed. For such trees as doe braunch round as it were in compasse, although they bee otherwise great, as namely, Apple trees & Pyrries, yet they yeeld no great shaddow: whereas a man shall see Cherrie trees and Lawrels take up an exceeding deale of ground with their shade. Now these shaddowes of trees have their properties by themselves, for that of the Walnut tree is noisome and K
hurtfull even to man, breeding heavinesse in the head: and an ill neighbour it is besides to all plants either under or neare unto it. The Pine tree also with her shaddow nippeth and killeth the young spring of all plants within the reach thereof. Howbeit, both it and also the Walnut tree resist the force of winds notably, and therfore they serve in good steed to protect vineyards, and are projected against the winds to breake their violence. The dropping of the Pine, Oke, and Mast-holme, by reason of the raine water wherewith they are much charged, is very heavie and ponderous, and therefore hurtfull. As for the Cypresse tree, it droppeth little or nothing, by reason that it receiveth so small a deale of raine: & in truth of all others the shade is least, the boughs are knit and trust so round, and run up sharpe pointed in the top. The Fig tree giveth no thicke shaddow, however the boughs spread large ynough; which is the cause, that no man forbiddeth L
the planting of them in Vineyards among Vines. And as for Elmes, their shade is so mild and thin, that it nourisheth whatsoever it overspreadeth under it. Howbeit, *Atticus* is of opinion, That the shaddow of Elmes is one of the thickest and most hurtfull: neither doe I make any doubt thereof, if they be let to spread into great armes and boughs at libertie: marie, if the braunches thereof, or of any tree within-forth be shrigged, I thinke that the shade will doe no harme at all. The Plane tree carieth a heavie head, and therefore casteth a thicke shade, howbeit, pleasant it is, and refresheth those that sit under it: safe resting there is upon the grasse, rather than the bare ground: and there is not a tree againe where grasse groweth thicker and longer, to cover the bankes and seats under it. As for the white Poplar or Aspen tree, it maketh little or no shade at all, the leaves keepe such a wagging and trembling, and never hang still. The shaddow of the Alder M
tree is fat and battle, it feedeth whatsoever is sowne or set under it. The Vine hath shade ynough to serve her owne turne: the leaves are ever stirring, and by their motion and turning often too and fro, there is a good temperature of shade and Sunne by that meanes: they serve also in steed of a couvert in time of raine, and beare off a good shower. Generally, all trees in manner that

have

A have their leaves hanging by a long taile, caſt but a light and ſlender ſhaddow. And in very truth the knowledge hereof would not be contemned, nor ſet in the laſt place of ſuch points as belong to husbandrie, conſidering there is not the ſhaddow of any one tree, but either is a kind nource, or a ſhrewd and curſt ſtepdame, that is to ſay, either profitable or incommodious to all the fruits of the earth. For without all queſtion, the ſhade of Walnut trees, Pine trees, Pitch trees, and Firs, is no better than poiſon to all that is within the compaſſe of it, and kils whatſoever it toucheth. And thus much of Shadowes.

As touching the dropping of trees, a man may conclude in one word all that belongeth thereunto. For looke what trees ſoever be ſo defended and clad with thicke leaved branches, that the raine cannot paſſe readily through them, bee ſure the dropping and diſtillation of ſuch is
B naught and daungerous. And therefore it skilleth very much in this matter and queſtion now in hand, to know the nature of the earth wherein wee meane to plant, how many trees it may well beare and nouriſh. As for hils, they require of themſelves not ſo great diſtance betweene tree and tree, as the plaines beneath: beſides, in ſuch places expoſed to the wind, it is good that they bee planted thicker. Howbeit, Olives require the greateſt ſpace betweene of all others: and therefore *Cato*, following the judgement of all Italie, ordaineth in theſe words, That they ſhould ſtand aſunder five and twentie foot at the leaſt, and thirtie at the moſt: but this rule holdeth not alwaies; for herein guided wee muſt bee by the nature and ſite of places, which varie and differ much. For in Bœtica, which is a part of Spaine, there is not another tree growing, bigger than the Olive: and if we may give credite to authors that have written hereof, there bee in Affricke, by their re-
C port, many of them called Milliariæ, for that every yeare they yeeld a thouſand pound weight of oile, apeece. And therfore *Mago* allowed threeſcore and fifteene foot every way, for diſtance betweene Olive trees, or els five and fortie at leaſt, even in leane and hard grounds, and thoſe that were expoſed to the winds. And in Bœtica verily, the people uſe to reape great plentie of corne among Olive trees.

Now of all other follies this is one, and bewraieth ſhamefull blindneſſe and ignorance, To be driven to make glades betweene trees when they be growne to a good bigneſſe: and namely, either by lopping their boughs too much for to let in light betweene, and ſo by this meanes to haſten their age and decay; or els to draw them by cutting them downe cleane: wherein oftentimes they that did ſet them at firſt, take themſelves in the manner, and blame their owne want of skill.
D Conſidering therefore, that there is no greater ſhame can happen to husbandmen than to repent when a thing is done, and then goe about to undoe it, much better it is of the twain in this caſe, to fault in overwide, than too ſtreight roume.

Chap. xiii.

What trees grow but ſlowly: and which they bee that ſoone come forward: alſo, of the Savine.

E Some trees by nature are ſlacke of growth, and principally thoſe that come of ſeed, and live longeſt. But ſuch as ſoone decay and die, are quicke of growth, as the Fig tree, Pomgranate tree, Plum-tree, Apple-tree, Peare-tree, Myrtle, and Willow: but they make amends for their ſhort life in this, that they goe before others in fruit, and enrich their maiſters quickly, for they begin to beare well at three yeares age, yea, and they make a ſhew thereof in their bloſſome before. Of all theſe the Peare-tree is the ſloweſt. But the Cypirus, as well the true and legitimate as the baſtard (which is a ſhrub called Pſeudo-Cypirus) come faſteſt forward of any other, for they beare at firſt both bloſſome and fruit. This is a generall thing obſerved, That all trees will thrive and proſper better, yea, and grow ſooner to perfection, if the ſhoots and ſuckers that put out at the root, as alſo other water twigs, be rid away, ſo that all the nouriſhment may bee turned to the principall ſtocke onely.

The worke of Nature in ſending out theſe ſprigs, taught us the feat to couch and lay ſets in
F the ground by way of propagation: and even after the ſame manner briers and brambles doe of themſelves put forth a new off-ſpring: for growing as they do, ſmall and ſlender, and withall running up to be very tall, they cannot chuſe but bend and leane to the ground, where they lay their heads againe, and take freſh root of their owne accord without mans hands: & no doubt, overgrow they would and cover the whole face of the earth, were they not repreſſed and withſtood by

by good husbandrie. The consideration whereof maketh mee to enter into this conceit, That men were made by Nature for no other end but to tend and looke unto the earth. See yet what a commodious device wee have learned by so wicked and detestable a thing as this bramble is, namely, to lay slips in the ground, and quick-sets with the root. Of the same nature is the Yvie also, even to grow and get new root as it creepeth and climbeth. And by *Catoes* saying, not onely the Vine, but Fig-trees and Olives also, will grow & encrease of cuttings couched in the ground; likewise Pomgranate trees, all kinds of Apple-trees, Baies, Plum-trees, Myrtles, Filberds, Hazels of Prænestе, yea, and Plane-trees. Now be there two waies to encrease trees by way of propagation or enterring their twigs. The first is, to force a braunch of a tree as it groweth, downe to the ground, and so to couch it within a trench foure foot square every way; and after two years to cut it atwo, where it bent from the tree; and after three yeares end to transplant it. But if a man list to have such plants or young trees to beare longer, the best way were to burie the said braunches at the first within mould, either in paniers or earthen vessels, that when they are once rooted, they might be removed all whole and entire in them, and so replanted. The second, is a more curious and wanton devise than this, namely, to procure roots to grow upon the very tree, by carying & conveighing braunches, either through earthen pots or oisier baskets, full of earth, thrust close unto the said braunches: and by this meanes, the branches feeling comfort of the warme earth enclosing them on every side, are easily intreated to take root, even among Apples & other fruits, in the head of the tree, (for surely by this meanes we desire to have roots to chuse, growing upon the very top.) So audacious are men and of such monstrous spirits, to make one tree grow upon another, far from the ground beneath. Thus in like manner as before, at two yeares end, the said impes or branches that have taken root, be cut off and caried away in the foresaid pots or paniers, thither where they shall grow. As for the Savine, an hearbe or plant it is that will take if it bee in this sort couched in the ground: also, a sprig if it be slipped off clean from the stocke, will come againe and root. Folke say, that if a man take wine lees, or an old bricke out of the wall broken small, and either poure the one, or lay the other about the root, it will prosper and come forward wonderfully. In like manner may Rosemarie be set as the Savine, either by couching it, or slipping off a branch from it; for neither of them both hath any seed. To conclude, the hearbe or shrub Oleander, may be set of an impe, and so grow, or els come of seed.

Chap. xiiii.

Of encreasing trees by seed: the manner of graffing one in another: how the fine devise of inoculation by way of scutcheon and emplaister was devised.

Nature not willing to conceale any thing from man, hath also taught him to engraffe trees with their seed and graine. For oftentimes it happeneth, that birds being hungrie, have greedily gobbled up seed and fruit whole and sound, which after they have moistened in their gorge, and tempered it also with the warmth and naturall heat of their stomacke, they send forth and squirt out againe when they meute, together with their dung, that giveth unto it a vertue of fecunditie, and so lay it upon the soft beds of tree leaves, which many a time the winds catch and drive into some clifts and cranies of the barke: by meanes whereof, wee have seene a Cherie tree upon a Willow, a Plane tree upon a Lawrell, a Lawrell upon a Cherie tree: and at one time Berries and fruits of diverse sorts and sundrie colours hanging at one and the same tree. It is said moreover, that the Chough or Daw hath given occasion hereof, by laying up for store, seeds and other fruits in crevises and holes of trees, which afterwards sprouted and grew. From hence came the manner of inoculation or graffing in the scutcheon, namely, to cut out a parcell of the barke of that tree which is to be graffed, with a sharpe knife made in manner of a shomakers nall-blade; & then to enclose within the said concavitie, the eie or seed taken out of another tree with the said instrument. And in old time verily this was the onely manner of inoculation used in Fig-trees and Apple-trees. *Virgil* teacheth us to open a concavitie in the knot or joint of a bud that driveth out the barke, and within it to enclose the gem or bud taken out of another tree. And thus much for the graffing that Nature hath shewed.

But there is another way of graffing, which casualtie and chaunce hath taught. And to say a truth, this Maister hath shewed well neare more experiments, now daily practised, than Nature her selfe. Now the manner of it came by this occasion: A certain diligent and painefull husband-

man,

A man, minding to mound and empale his cottage round about with a fence of an hedge; to the end that the ſtakes ſhould not rot, laid a ſill under them, of Ivie wood: but ſuch was the vitall force of the ſaid Ivie, that it toke hold faſt of the ſtakes and claſped them hard, inſomuch as by the life thereof, they alſo came to live; and evident it was to the eye, that the log of Ivie underneath, was as good as the earth to give life and nouriſhment unto the ſtakes afore-ſaid.

To come then unto our graffing, which wee learned by this occaſion: firſt, the head or upper part of the ſtocke muſt be ſawed off very even, & then pared ſmooth with a ſharpe garden-hook or cutting-knife: which done, there offereth unto us a two-fold way to performe the reſt of the worke: The firſt is, to ſet the graffe or Sion betweene the barke and the wood: for in old time truly, men were afraid at firſt to cleave the ſtocke; but ſoone after they ventured to bore a hole
B into the very heart of the wood: and then they ſet faſt into the pith juſt in the mids thereof, but one Sion or graffe; for by this kind of graffing, impoſſible it was that the ſaid pith ſhould receive or beare any more. But afterwards they deviſed a finer and more ſubtle invention to graffe, by cleaving the ſtocke gently through the mids; and after this manner they might well ſet into it ſix imps or Sions at once: as being perſuaded, that by ſuch a number they might ſupply the defect of any, if they chaunced to die or miſcarrie any way. Now when the ſaid clift was made, they held it open with a wedge of wood put betweene, untill ſuch time as the impe or graffe beeing thwitted thin and ſharpe beneath, were ſet handſomely cloſe within the rift. In the practiſe of which feat, many points are to be obſerved: firſt and foremoſt, it would be conſidered, what trees will thus ſort togither and be united; namely, what ſtocke will beare this manner of engraffing,
C and of what tree an impe or Sion will agree well to be ſet into it: for be ye ſure of this, all trees are not alike, neither have they all their ſap in one and the ſame part. Vines and Figge trees are drier in the mids of the tree, than in the head; and toward the top they are more apt to take and conceive, and therefore from thence it is good to make choiſe of impes to be graffed. Contrariwiſe, the ſap of Olives is moſt frim about the mids, and from thence they affourd Sions; for the tops are drie. Moreover, ſooneſt of all other doe thoſe trees incorporate one into another, if when the ſtock and graffe have barks both of one nature, if they bloſſome togither at one time, if they bud and put forth their ſpring at the ſame ſeaſon, and laſt of all, if their ſaps doe agree one with another. On the other ſide, long it will be ere they take, when the ſtock is drie and the graffe moiſt; or when the barke of the one is tender, and of the other tough and hard. Over and be-
D ſides, carefull heed muſt be taken in this buſineſſe, That the ſtocke is not cloven in a knot; for the churliſh hardneſſe thereof will not willingly receive and entertaine a gueſt: that choiſe alſo be made of the ſmootheſt and faireſt place in the ſtocke, where the graffe would be ſet: *Item*, That the clift be not above three fingers deepe; that it be ſtreight and direct; and laſtly, that the impe ſtand ſo cloſe barke to barke in the ſocket, that a man may not ſee betweene it and the ſtocke. *Virgil* will in no wiſe have a Sion or graffe to bee taken from about the top of a tree, for ſuch are all naught. But this one thing is generally held for certain, That the good imps to be graffed are thoſe, which bee gathered from thoſe armes of the tree which regard the Sun-riſing in ſummer time: *Item*, That all ſuch graffes come from the boughs that beare well: alſo that they bee new tender ſhoots of the laſt yeare (unleſſe they are to be graffed in the ſtocke of an old tree, for then
E there ſhould be choſen ſuch as are ſtronger:) moreover, this is to be regarded, that they be well budded, yea and knotted too, making ſhew and giving good hope even then, that they would beare fruit the ſame yeere: but in any wiſe the ſame ought to be of two yeares growth at leaſt, and not ſmaller beneath toward the ſtock than a mans middle finger. As for the graffes, the manner is to ſet them in the ſtocke with the leſſer end downward, when our purpoſe is, that the tree ſhould ſpread rather in breadth, than run up in heigth. Above all, it would be looked well unto, that they be neat and bright, ſo as they ſhine againe; that no part of them be ſeene either ſcorched drie with the ſunne, or cicatrized (as it were) and bliſtered. Good hope there is that the graft will take, if the pith or marow of the ſion doe fall jumpe with the joynt, ſo as it joyne cloſe to the wood and inner barke of the mother ſtocke: for this is farre better than to let it meet juſt
F and even with the bark without-forth. Moreover, a carefull eie muſt be had in thwitting & ſharpning the graffe or impe, that the heart or woodie ſubſtance bee not ſtript all naked, or left bare: howbeit gently and with a light hand a man muſt goe over it with a fine and ſharpe inſtrument, in ſuch ſort, as it may goe downe into the clift wedgewiſe, no deeper than three fingers bredth: the which may right eaſily be done, if it be ſhaven and pared preſently after it hath been dipped

in water. Moreover, wee ought be well advised, that wee sharpen not the end of a graffe in the G
wind, and that the barke goe not either from it or the stocke. As for the graffe it selfe, it must be
driven downe into the clitt, close to the shoulder where the owne barke goeth round, and from
whence you began to sharpen it: but take heed in thrusting and forcing thereof, that it stand not
out of joynt, ne yet that the barke thereof turne up in wrinkles: and therefore chosen they would
not be which are over moist, no more (I assure you) than those that be too drie; for as the ex-
cessive humiditie of the one looseneth the rind, so the want of vitall moisture in the other, will
not suffer it to unite and concorporate. Over and besides, in the working of this feat, men observe
a certaine religious reverence, namely, that the sions be set into the stocke when the moone is
croissant, (to wit, before the full) and with both hands forsooth, or els all is marred: and other-
wise in this businesse there is an opinion, that two hands togither are put to smaller streste, and H
have better stay of themselves than one alone; and therefore such a moderation is right neces-
sarie: for the more forcibly the graffes be set into the stocke, & the faster that they are setled, the
longer it will be ere they take to beare; but surer they be, and continue the longer: contrariwise,
if they stand slacke, the tree indeed will the sooner beare, but last the lesse while. Furthermore,
regard would be had in this case, as well that the clift of the stocke gape not too much (as being
over wide for the graffe;) as that it be not too little and over-streight, for feare that either it flurt it
out againe, or claspe it and gird it so hard that it kill it quite. This principally we must take heed
of at the first, that there be no spill or little chip left behind in the mids of the clift, nor any thing
besides the graffe it selfe, to fill up the place. Some there be, that enter the clift first in the stocke,
with a bill, and with an osier twig tye and bind up the very brims or edges thereof: which done, I
they drive the wedges in, to make such an overture as is meet; for by reason of the foresaid
bonds, they need not feare the gaping of it too wide. Some stocks there be which the very same
day that they bee graffed in the nource-garden, are without any harme remooved to the place
where they must grow. If the stocke wherein you graffe be bigge and round, the best way is to set
the sion betweene the barke and the wood thereof, and to devide the one from the other with a
wedge of bone, least in enlarging of the barke it chaunce to breake. In graffing of a Cherie tree
stocke, the over rind or barke would bee taken away before the clift bee made. [Now these trees
alone of all others may be graffed very well presently after mid-winter.] When the said rind is
gone, you shall see therein a certaine downe, which if it chaunce to claspe about the graft, it rot-
teth the same incontinently. But to returne againe to our worke of graffing: After the wedge is K
taken forth whole and sound at the point, (which is a token that no spill remaineth within) you
may bee bold to bind the head of the stocke all about. Yet this would be considered by the way
(which I had like to have forgotten) that the best and handsomest graffing, is as near the ground
as may be, in case the knots will give leave and the stocke beare it: also that the grafts would not
conveniently stand without the stocke above six fingers breadth. Now when all is done and sure
worke made (as hath been said) *Cato* willeth us to take clay, or the sandie grit of chalke, mixed
togither with oxe or cow shearn, to worke & temper all these togither in manner of a tough past
or cataplasme, and then to lay the same within the clift, & round about to daube all. And verily
by this and other such rules which he hath left in writing, it appeareth plainly, that in those daies
the manner was to graffe betweene the barke and the tree, and not otherwise; as also to set the L
sions in the stocke, not above two fingers deepe. As for Apple trees and Pyrries, he prescribeth
that they should be graffed in the Spring; also fiftie daies after the Summer sun-stead, & againe
after vintage: but Olives and Fig trees in the Spring onely, observing the age and disposition of
the Moone, when she is in the wane and thirstie, that is to say, drie: moreover, after noontide,
and when no Southerne wind doth blow. And I cannot chuse but wonder much at the curiosi-
tie and double diligence of *Cato*, who not content to have defended the graft with clay or past
aforesaid, yea and to preserve it with turfe and mosse against the injurie of rain and cold, to have
bound it about also with little knitches of soft osier twigs slived in twaine; but must give charge
besides to cover it with Oxe-tongue (a kind of hearb there is so called) *i.* Bugloss: and yet he
hath not done, but the same must be fast bound with wispes and wreaths of straw and litter aloft. M
Now adaies men make no more adoe, but thinke it sufficient to stop and close up barke and all,
with earth or clay and chaffe tempered togither; thinking it sufficient, if the graft beare out two
fingers breadth above. They that wait upon the Spring season for to graffe, are many times
driven to their shifts for want of time, by reason that all trees make hast then to bud, & do break

out

A out of a ſodain; unleſſe it be the Olive, the oilets or eyes whereof be longeſt while in comming forth, as having leaſt ſap of all other, running under the barke; the which if it were overmuch, would ſtifle and choke the grafts. As for the Pomegranat and Fig tree, howſoever otherwiſe they ſeeme to be drie, yet good it is not to deferre and put off the grafting of them. The Peare-tree may well enough be graffed with the bloſſome on the head, and it makes no matter if a man doe ſtay, and graffe it within the moneth of May. To be ſhort, if a man bee conſtrained to fetch his ſions or imps of Apple trees and ſuch like, farre off, it is thought that they will keepe their ſap beſt, if they be ſtucke or ſet faſt in a Rape root. Alſo if one would preſerve them a certaine time before they ſhould be occupied, it is paſſing good to lay them cloſe between two creſt tiles, well ſtopped on every ſide with earth, and that neare to ſome rivers or fiſh-ponds.

B

Chap. xv. *The manner how to graffe a Vine tree.*

AS for the cuttings or ſets of Vines, they may bee kept well a long time, covered all over with ſtraw or litter in drie ditches; and afterwards they are to be laid within the earth, all hilled or covered, ſave only that their heads be ſeene above ground. *Cato* graffeth a vine ſtocke three manner of waies: Firſt, he willeth that the mother ſtocke ſhould be cut overthwart, and then cloven through the very pith or heart in the mids, wherein hee would have the young imps (thwitted and ſharpned as is beforeſaid) to be ſet and engraffed ſo, as the marow of the one and the other may joyne and meet juſt togither. The ſecond manner is, when two vine ſtocks do reach one to the other, for to cut byas or aſlaunt (after the manner of a Goats foot) two twigs or
C braunches, of either one, with this regard, that theſe cuts be of a contrarie ſide the one unto the other, and withall ſo deep, as that they come unto the pith or heart; then to fit one to the other, joyning pith to pith, and then binding them faſt togither ſo cloſe, that no aire may enter between, untill ſuch time as the one hath adopted the other. The third deviſe is, to bore holes in an old vine, not directly but aſlope, as far as to the pith; and then to put into them young imps two foot long, and to bind them faſt: which done, to make a certaine batter or morter [with clay, beaſt dung, and ſand togither] and therewith to dawbe the place; but with this regard, that the graft ſtand halfe upright or ſomewhat leaning. This manner of grafting hath been checked and corrected of late daies by our countrymen, who leaving the hand-piercer have taken the French vibrequin or breaſt-wimble, which gently and quickly boreth a hole, and hurteth not the wood:
D for all chafing heat cauſed by the ſaid piercer, dulleth the vigor both of ſtocke and impe. Alſo they have deviſed, that the ſaid impe to be engraffed, be gathered from the tree when it beginneth to bud or burgen; & when it is ſet into the ſtocke, that it be left ſtanding out with no more than two eyes or buds out of the grafting place; that it be well bound alſo with the winding rods of an Elme: moreover, that on either ſide of it, the mother-ſtocke be ſlit or cut in two places on both ſides, to the end that from thence rather than otherwiſe, the wateriſh humour may diſtill and drop forth, which of all things hurteth vines moſt. After all this, they would have the ſaid graffe remaine bound, untill ſuch time as it have put foorth ſhoots two foot long; and then the foreſaid bands to be cut in ſunder, that they may burniſh in thickneſſe and at eaſe accordingly. The ſeaſon which they have allowed for to graft vines, is from the Æquinoctiall in Autumne
E unto the time that they begin to bud foorth. Generally all trees that are tame and gentle, may well be graffed into ſtockes and roots of the wild, which by nature are more drie: contrariwiſe, graffe the wild and ſavage kind upon the other, you ſhall have all degenerate, and become wild. Touching other points belonging to the feat of grafting, all dependeth upon the goodneſſe or malignitie of the skie and weather. In ſumme, a drie ſeaſon is good for all trees grafted in this manner: and ſay that the drought were exceſſive, there is a good remedie for it, namely, to take certaine earthen pots of aſhes, and to let water diſtill through them ſoftly, by little and little to the root of the ſtock. As for inoculation, it loveth ſmall dewes otherwhiles, to refreſh both ſtock, ſcutcheon, and oilet.

Chap. xvi.

F *Of Emplaſtration or graffing with the Scutcheon.*

THe manner of graffing by way of emplaſtre or ſcutcheon, may ſeeme alſo to have come from inoculation: and this deviſe agreeth beſt with thoſe trees that have thicke barkes, as namely Fig trees. To goe therefore artificially to worke, the mother ſtocke or tree to bee

graffed, must be well rid and cleansed from the braunches all about the place where you meane G
to practise this feat, because they should not sucke the sap from thence; and chuse the neatest
and trimmest part, which seemeth most fresh and lively: then cut forth a scutcheon of the barke,
[but be carefull that your instrument pierce no farther than the barke, nor enter into the quicke
wood:] which done, take from another tree the like scutcheon of the barke, saving the eye or
bud thereon, and set it in the place of the other; but so equall this must be to the place and so
close joyned and united to it, that a man may see no token at all or apparence in the joynt, of
any wound or skarre made; to the end, that presently they may concorporate, that no humor of
the sap may issue forth, nor so much as any wind get between: and yet to make sure worke, the
better way is to lute it well and close with clay, and then to bind it fast. This devise of grafting thus
with the scutcheon, was but lately found out, by their saying, that favour all new and moderne in- H
ventions: howbeit I find that the auncient Greekes have written thereof; yea and *Cato* also our
owne countryman, who ordained to graffe both Olive and Fig tree in that order: and (as he was
a man very diligent and curious in all things that he tooke in hand) hee hath set downe the just
measure and proportion of the scutcheon: for hee would have the barkes both the one and the
other, to be cut out with a chizell foure fingers long, and three in breadth, and so to close up all
in manner aforesaid, that they might grow together; and then to be dawbed over with that mor-
ter of his making aforesaid: after which manner, Apple trees also may be graffed.

Some there be, who have intermingled and comprehended under this kind of graffing with
the scutcheon, that devise of making in the side a cleft, and namely in vines; for they take forth
a little square peece with the barke, and then set in an impe very hard and close, on that side where I
it is plaine and even, to the very marow or pith. Certes, neare to Tuliæ in the Tyburtines coun-
trey, I have seene a tree graffed all these waies abovesaid, and the same laden with all manner of
fruits; one bough bearing Nuts, another Berries, here hung Grapes, there Figs; in one part you
should see Peares, in another Pomegranats; and to conclude, no kind of Apple or other fruit,
but there it was to be found: mary this tree lived not long. Howbeit, let us use what diligence we
can, yet never shall we be able with all our experiments, to attaine unto the depth of Natures se-
crets. For some trees there be, that come up of themselves, and by no Art and industrie of man
will be made to grow; such also love ordinarily to be in wild forrests and in rough desarts, where
they prosper well: whereas the Plane tree will beare all manner of graffing best of any other;
and next unto it, the wild hard Oke: but both the one and the other corrupt and marre the tast K
of what fruit soever is graffed thereupon. Some trees there be, that refuse not to be engraffed up-
on any stock, and what way soever they be graffed it skills not, as Fig trees and Pomegranat trees.
As for the Vine, it will not beare the scutcheon; neither any tree besides that hath a thin barke,
or which doth pill and rift: no nor such as be dry or have small store of sap within them can away
with inoculation. Howbeit this manner of graffing is most fruitfull of all other; and next to it,
that which is done by way of scutcheon or emplastre: yet trees so graffed, be of all others most
tender and feeble: as also such as rest and stay upon the barke only, are with the least wind that
is, soonest displanted and laid along on the ground. The surest and strongest way therefore is, to
graffe imps upon the head of a stocke, yea and more plentifull by farre than to sow them of seed,
or plant them otherwise. L

Chap. xvii.

An historie, shewing the example and proofe hereof.

IN this discourse and question concerning grafts, I cannot passe over the rare observation of
one example, practised by *Corellius* a knight of Rome borne at Ateste: This gentleman of
Rome, in a ferme that he had within the territorie of Naples, chaunced to graffe a Chestnut
with an impe cut from the same tree: This graft tooke and bare faire Chestnuts and pleasant to
the tast, which of him tooke their name. After the decease of this gentleman, his heire (who had
been sometime his bondslave and by him enfranchised) grafted the foresaid Corellian Chestnut M
tree a second time: and certainly betweene them both was this difference, The former Corel-
lian bare the more plentie, but the nuts of the other twice graffed were the better. As for other
sorts of graffing or planting, mans wit hath devised, by observing that which hath falne out by
chaunce: thus are we taught to set broken boughs into the ground, when wee saw how stakes pit-

ched

A ched into the earth,tooke root.Many trees are planted after that manner,and eſpecially the Fig tree, which will grow any way, ſave onely of a little cutting: but beſt of all, if a man take a good big braunch thereof, ſharpen it at the end in manner of a ſtake, and ſo thruſt it deepe into the ground, leaving a ſmall head above the ground, & the ſame covered over with ſand. The Pomegranat likewiſe and the Myrtles, are ſet of braunches, but the hole firſt ought to bee made eaſie and large with a ſtrong ſtake or crow of yron. In ſumme, all theſe boughs ought to be three foot long, ſmaller in compaſſe than a mans arme, ſharpned at the one end, and with the barke ſaved whole and ſound with great care. As for the Myrtle tree, it will come alſo of a cutting; the Mulberrie will not otherwiſe grow: for to couch and plant them with their braunches, we are forbidden, for feare of the lightnings. And foraſmuch as we are falne into the mention of ſuch cuttings,
B I muſt now ſhew the manner of planting them alſo: above all things therefore regard would be had, that they be taken from ſuch trees as be fruitfull, that they be not crooked, rough, and rugged, nor yet forked; ne yet ſlenderer than ſuch as would fill a mans hand, or ſhorter than a foot in length. *Item*, That the barke be not broken or raſed; that the nether end of the cut be ſet into the ground, and namely, that part alwaies which grew next the root; and laſt of all, that they be banked well with earth about the place where they ſpring and bud forth, untill ſuch time as the plant have gotten ſtrength.

Chap. xviii.

C *The manner of planting, ordering, and dreſſing Olive trees. Alſo which be the convenient times for graffing.*

WHat rules (by the judgement of *Cato*) are to be obſerved in the dreſſing and husbanding of Olives, I thinke it beſt to ſet downe here word for word, as he hath delivered them. Thus he ſaith therfore: The truncheons or ſets of Olive trees which thou meaneſt to lay in trenches, make them three foot long; handle them gently and with great care, that in cutting, ſharpning, or ſquaring them, the barke take no harme nor pill from the wood. As for ſuch as thou doeſt purpoſe to plant in a nource-garden for to remoove againe, ſee they be a foot in length, and in this manner ſet them: Let the place be firſt digged throughly with a ſpade untill it be well wrought, lie light, & brought into temper: when thou putteſt the ſaid truncheon
D into the ground, beare it down with thy foot; if it go not willingly deepe enough by that means, drive it lower with a little beetle or mallet; but take heed withall, that thou rive not the barke in ſo doing. A better way there is, To make a hole firſt with a ſtake or crow before thou ſet it into the ground, and therein maiſt thou put it at eaſe, and ſo will it live alſo and take root the ſooner: when they be three yeeres old, have then a carefull eye to them in any caſe, and marke where and when the barke turneth. If thou plant either in ditches or furrowes, lay three plants togither in the earth, but ſo as their heads may ſtand a good way aſunder above the ground; alſo that there be no more ſeene of them than the breadth of foure fingers; or els (if thou thinke good) ſet the buds or eies only of the Olive. Moreover, when thou art about to take up an Olive plant for to ſet againe, be warie and carefull that thou breake not the root: get as many ſpurs or ſtrings thereof
E [called the beard] as thou canſt, earth and all about them: and when thou haſt ſufficiently covered thoſe roots with mould in the replanting, be ſure thou tread it down cloſe with thy foot, that nothing hurt the ſame.

Now if a man demaund and would gladly know what is the fitteſt time for planting Olives, in one word I will tell him; Let him chuſe a drie ground in ſeed time [*i.* in Autumne,] and a fat or battle ground in the Spring: furthermore, begin to prune thy Olive trees fifteen daies before the Æquinox in the Spring, and from that time forward for the ſpace of fortie daies, thou canſt not doe amiſſe. The manner of pruning or disbraunching them, ſhall be thus, Looke where thou ſeeſt a place fertile, if thou ſpie any drie or withered twigs, or broken boughs that the wind hath met withall, be ſure thou cut them away every one: but if the plot of ground be barraine,
F eare it up better with the plough, take paines (I ſay) to till it well, to breake all clots and make it even; to cleanſe the trees likewiſe of knurs and knots, and to diſcharge them of all ſuperfluous wood: alſo about Autumne bate the earth from about the roots of Olives, and lay them bare, but in ſtead thereof put good mucke thereto. Howbeit if a man do very often labour the ground of an Olive plot, and take a deepe ſtitch, hee ſhall now and then plough up the ſmalleſt roots

thereof, so ebbe they will run within the ground, which is not good for the trees: for in case they G
spread aloft, they will wax the thicker, and so by that means the strength and vertue of the Olive will turne all into the roots.

As touching all the kinds of Olive trees, how may they be; also in what ground they ought to be set, and wherein they will like and live best; likewise, what coast of the heaven they should regard; we have shewed sufficiently in our discourse and treatise of Oile. *Mago* hath given order in his bookes of husbandrie, that in planting them upon high grounds, in drie places, and in a veine of clay, the season should bee betweene Autumne and midwinter: but in case you have a fat, moist, or watersh soile, hee setteth downe a longer time, namely, from harvest to midwinter. But this rule of his you must take to be respective to the climat of Africke only: for in Italy at this day verily, men use to plant most in the Spring: howbeit if a man hath a mind to be doing H
also in Autumne, hee may be bold to begin after the Æquinox; for during the space of fortie
* Vergiliæ. daies togither, even to the setting of the * Brood-hen starre, there are no more but fourteene daies ill for planting. In Barbarie, the people have this practise peculiar to themselves, For to graft in a wild Olive stocke; whereby they continue a certaine perpetuitie: for ever as the boughs that were grafted and (as I may say) adopted first, wax old and grow to decay, a second quickely putteth forth a fresh, taken new from another tree, and in the same old stocke sheweth young and lively; and after it a third successively, and as many as need; so as by this meanes they take order to eternize their Olives: insomuch as one Olive-plot hath been knowne to have prospered in good estate, a world of yeares. This wild Olive aforesaid, may be graffed either with sions set in a clift, or els by way of inoculation with the scutcheon aforesaid. But in planting of Olives, I
this heed must be taken, that they be not set in a hole where an Oke hath been stocked up by the root: for there be certain canker-worms (called Erucæ in Latine, or Raucæ) breeding in the root of an Oke, which eat the same, and no doubt will doe as much by the Olive tree. Moreover, it is found by experience better for Olive trees, that their sets be not interred in the earth, nor yet dried, before they be planted. Also, the same experience hath taught, that for old Olive trees (overgrowne with a kind of mossie skurfe) it is passing good, ech other yeare to scrape and claw them well, betweene the Spring and Æquinox, and the rising of the star Vergiliæ or the Brood-hen: likewise to bestow mosse round about the root: mary every yeare they would bee digged round about the root and laid bare after the sunstead, with a trench made two cubits broad and a foot deepe: as also once in three yeeres, it were not amisse to cherish them with good dung. K
Over and besides, the same *Mago* saith, that Almond trees ought to bee planted betweene the setting of Arcturus and the shortest day of the yeare. As for Peare trees, they are not to be set all at one and the same time, for they blossome not all alike: they that beare either the long or round Peares, have their season from the occultation of the Brood-hen starre, untill midwinter. All other sorts, and principally those that regard either the East or the North, are to be planted in mid-winter, namely, after the retreat of the starre called Sagitta, [*i.* the Shaft.] The Lawrell would bee put into the ground, from the Ægle starre; unto the fall of the Shaft aforesaid: for certeinly the observation of the time, pertinent to planting of trees, agreeth much-what after this manner; and for the most part men doe accord and ordaine, that it should be done in the Spring and Autumne principally. Another season there is about the rising of the Dog-starre, L
which few men take knowledge of, because it is not so generally practised, nor found alike profitable to all countries: howbeit I must not overpasse it in silence, considering that my purpose is not to speake of this or that countries disposition, but to search into the nature of all things. In Cyrenaica therefore (a region in Africke) they use to set trees about the time that the Etesian Northern winds doe blow: in Greece likewise they doe the same; and namely in Laconia they suppose that to be the best time for the Olive tree: and in the Iland Cos, the manner is then to plant vines also. In all other parts of Greece, they make no doubt to inoculate, and to graffe in that season; but in no wise will they plant whole trees then. But herein it skilleth much to consider the nature of each tract and region: for in Ægypt, they set, plant, and replant, every moneth of the yeare: in Æthiopia likewise, and India; and generally in all countries whersoever M
it raineth not in Summer. Setting these respects aside, trees require of necessitie to be planted in Autumne. Like as therefore there bee three seasons of planting trees, so there are as many wherein they bud and put foorth new shoots; to wit, the Spring, the rising of the Dog-starre, and the apparition of Arcturus. And verily this is a thing worthie to be noted, That not onely

A beasts and other living creatures have an appetite to engender, but the earth also, and all the plants thereupon, are much more lustie and hote that way. And therefore to make them to conceive in due season, the time would be well observed, when they bee as it were in love, and desire the act of generation. And not onely in the earth and trees therein planted, is this to bee seene, but in grafts and stockes also particularly by themselves; since that they have a mutuall and respective appetite, one to joine & incorporat with the other. They that make choise of the Spring for this purpose, begin to put them as it were together for to engender, presently after the Æquinoctiall; giving out in these plaine tearmes, that trees then are broodie and readie to put foorth sprouts: which is the reason, that their barkes at such a time will knit and joine together easily. But such as preferre the Autumne before the Spring, fall to this businesse immediately upon the
B rising of the star Arcturus; for then they suppose, that plants will take root forthwith, and by the time that the Spring is come, they will bee better prepared to put forth lustily: considering that their vertue is not streightwaies spent in budding, but rather employed in taking good root. Howbeit, some trees there be that have their set times and seasons of the yeare limitted, whether it be to plant or to graffe: and the same indifferently in all places, as namely, Cherrie-trees and Almond trees about the midwinter. But for the most part, the situation of the place will be able to guide and order all this matter best: for cold and wateriſh grounds ought to be planted in the Spring; but drie and hote, in the Autumne. With our peasants here in Italie, it is ordinarie to devide their times and seasons for planting in this manner following, They set out for the Mulberie all the time from the Ides of Februarie to the spring Æquinox: for the Peare tree they allow the
C Autumne, and so forward untill fifteene daies before the point of midwinter, and no longer: for Summer Apples and Quinces, for Servises likewise and Plums, they assigne the space betweene the Winter tropicke or Sunnestead, and the Ides of Februarie. As for Carobes of Greece, and Peach-trees, they have all the Autumne and the whole yeare before them untill mid-winter approch. All Nut trees, as namely, Walnut trees, Pine trees, Filberds, Hazels, and Chestnut trees, would be planted from betweene the first day of March, and the fifteenth thereof. To conclude, the onely time for Willowes & Broome, is about the Calends or beginning of the same March. But of these two last named, the Broome loveth to be set of nource-plants, comming of seed, in drie and light grounds: but contrariwise, the Willow to be set of twigs in moist places, according as we have before said.
D

Chap. xix.

What trees they be that love to sort and keepe companie together. The skill and feat of baring the roots of trees, and also of hilling or banking them about.

THere is besides a new manner of grafting trees, which I will not overpasse: for my purpose is not willingly to omit ought, that I have found in any booke as touching this argument. And *Columella*, as himselfe affirmeth, was the first deviser thereof, namely, to conjoine trees of diverse natures, and such as otherwise cannot abide societie and fellowship together, as for example, Fig trees and Olive trees. He, I say, would have a Fig tree to bee planted neare unto an O-
E live, and so neare indeed, as that a bough or braunch of the Olive may reach unto the Fig tree at ease, considering that it is very supple and pliable otherwise, and readie to follow and bee led as a man would have it: and yet as obedient as it is, hee would have it ever and anone to be handled and made gentle in the meane time, that by this meanes inured first, it may be bent and bowed to the purpose when the time serves. Which done, after that the Figge tree hath gotten some strength, and is growne to sufficient bignesse for to beare a graffe (which ordinarily is at three yeares end, or at the utmost when it is five yeares old) the head thereof must bee cut or sawed off, and then the braunch or bough of the Olive beforesaid, beeing well cleansed and made neat, and the head-end thereof (as is beforesaid) thwited and scraped sharpe, howbeit, not yet cut from the mother stocke, must bee set fast in the shanke of the Figge tree, where it must bee
F kept well and surely tied with bands, for feare, that thus beeing forced and graffed arch-wise, it start and flurt not out againe, and returne to the owne. Thus beeing of a mixt and meane nature, betweene a braunch or bough growing still unto the tree, and yet laid in the ground to take new root, and an impe or sion graffed, for the space of three yeares it is suffered to feed and grow indifferently betweene two mothers, or rather by the meanes thereof, two mother-

stockes

stockes are growne and united together. But in the fourth yeare it is cut wholly from the owne G
mother, and is become altogether an adopted child to the Fig-tree, wherein it is incorporate. A pretie devise, I assure you, to make a Figge-tree beare Olives, the secret whereof is not knowne to every man: but I my selfe doe conceive and see the reason of it well ynough.

Moreover, the same regard and consideration above rehearsed, as touching the nature of grounds, whether they bee hote, cold, moist, or drie, hath shewed us also the manner of digging furrowes and ditches. For in waterie places it will not bee good to make them either deepe or large: whereas contrariwise, in a hote and drie soile they would be of great capacitie, both to receive and also to hold store of water. And verily, this is a good point of husbandrie for to preserve not onely young plants, but old trees also. For in hote countries, men use in Summer time to raise hillockes and bankes about their roots, and cover them well therewith, for feare least the H
extreame heat of the Sunne should scorch and burne them. But in other parts the manner is to dig away the earth, and to lay the roots bare, and let in the wind to blow upon them. The same men also in winter doe banke the roots about; and thereby preserve them from the frost. Contrariwise, others in the winter open the ground for to admit moisture, to quench their thirst. But in what ground soever it be where such husbandrie is requisite, the way of cleansing tree roots, and ridding the earth from them, is to dig a trench three foot round about. And yet this must not bee done in meddowes, for as much as for the love of the Sunne, and of moisture, the roots of trees run ebbe under the face of the earth. And thus much verily may suffice in generall, for the planting or graffing of all those trees that are to beare fruit.

Chap. xx. I

Of Willow and Oisier plots: of places where reeds and canes are nourished: also, of other trees that be usually cut for poles, props, and stakes.

IT remaineth now to speake of those trees which are planted and nourished for others, and for Vines especially: to which purpose, their wood is usually lopped to serve the turne. Among which, Willowes and Oisiers are the cheefe, and to bee placed in the formost ranke: and ordinarily they love to grow in moist and waterie grounds. Now, for the better ordering of the Oisier, the place would be well digged before, and laid soft two foot and a halfe deep, and then planted with little twigs or cuttings of a foot and a halfe in length, and those prickt in: or else stored with good big sets, which, the fuller and rounder they be in hand, so much better they are for to K
grow, and sooner will they prove to be trees. Betweene the one and the other, there ought to bee a space of sixe foot. When they are come to three yeares growth, the manner is to keepe them downe with cutting, that they stand not above ground more than two foot, to the end that they might spread the better in breadth, & when time serves be lopped and shred more easily, without the helpe of ladder. For the Withie or Oisier is of this nature, that the nearer it groweth to the ground, the better head it beareth. These trees also, as well as others, require (as men say) to have the ground digged and laid light about them every year, in the month of Aprill. And thus much for the planting and ordering of Oisier willowes, which must bee emploied in binding and winding. As for the other Willow, which affourdeth big boughs for poles, perches, and props, those I
may bee set likewise of twigs and cuttings, and trenched in the ground after the same manner. These lightly every fourth yeare will yeeld good poles or staves, and for that purpose would they then be ordinarily cut and lopped. If these trees become old, their boughs by propagation may still maintaine and repleni sh the place, to wit, by couching them within the ground; & after they have lien so one yeare, and taken root, by cutting them cleane from the stocke-father. An oisier plat of one acre stored thus, will yeeld twigs sufficient for windings and bindinds, to serve a vineyard of five and twentie acres.

To the same purpose men are wont to plant the white Poplar or Aspe, in manner following. First, a peece of ground, or a quarter, must be digged and made hollow two foot deepe: and therein ought to be laid cuttings of a foot and a halfe in length, after they have had two daies drying: N
but so, as they stand one from another, a foot and a handbreadth, & be covered over with mould two cubites thicke.

As touching canes and reeds, they love to grow in places more wet and waterish than either the Willowes and Oisiers abovesaid, or the Poplars. Men use to plant their bulbous roots, which

some

A ſome call their oilets or eies, in a trench of a ſpan deapth: and thoſe two ſoot and an halfe aſun-
der. Theſe reeds doe multiplie and encreaſe of themſelves (if a plot be once planted with them)
after the old plants be extirped & deſtroied. And ſurely, this is found now adaies to bee the better
and the more profitable way, even to commit all to Nature, rather than to gueld and weed them
out where they ſeeme to grow over thick, as the practiſe was in old time: for the manner of their
roots is, to creepe one within another, and to be ſo interlaced continually, as if they were twiſted
together. The fit and proper time to plant and ſet theſe canes or reeds is a little before the Ca-
lends of March, to wit, before the oilets or eies aboveſaid begin to ſwell. They grow untill mid-
winter, at which time they waxe hard, which is a ſigne that they have done growing: and this is
the onely ſeaſon alſo for to cut them. Likewiſe, the ground would be digged about them, as of-
B ten as Vines. The order of planting them is two manner of waies, for either the roots bee laid
overthwart or acroſſe, and but ſhallow within the ground (and looke how many eies there bee in
the root, ſo many plants will ſpring above the earth:) or elſe they be pitched downe right, within
a grave or trench of a foot deapth, ſo as there bee two eies or buds under the ground, and the
third above, but cloſe and meet with it: but this caveat is to be given, that the head thereof may
bend forward toward the earth, for feare that it drinke in any deaw, which might ſtand and ſettle
upon it. This alſo is obſerved, that they be cut ever in the wane of the Moone: as alſo, before that
they are emploied about Vineyards for to beare up Vines, they would have a whole yeares dry-
ing, for ſuch are more profitable than the greene.

The beſt ſtaies to beare up Vines, are made of the Cheſtnut tree: for why? the wood is gen-
C tle and tractable; tough withall, and enduring long: beſides, it hath this propertie, that cut it
when you liſt, it will ſpring againe more plentifully than any Willowes. It loveth to grow in a
gentle and ſandie ground, but principally, if the ſame ſtand upon a moiſt gravell or a hote earth
full of little pebbles, and namely, where there is good ſtore of ſuch ſoft ſtones, as will ſoon crum-
ble into grit: neither makes it any matter how much the place be ſhaddowed, nor how cold and
expoſed to the Northerne winds, for ſuch it liketh well ynough, yea, although it bee the ſide or
hanging of an hill, as bleake and cold as may bee. But contrariwiſe, it may not abide the red
French earth, the chalkie or marle ground, nor in one word, any that is battle and fruitfull. Set it
is of a Nut, as we have beforeſaid: but it commeth not up, unleſſe there bee five in a heape piled
together, and thoſe of the faireſt and biggeſt ſort. Moreover, the plot wherein you meane to have
D Cheſtnuts grow, muſt be ouvertly broken up aloft, from betweene November and Februarie: in
which time the Nuts uſe to bee looſe, and to fall of themſelves from the tree, and ſpring under-
neath, finding the ground light and hollow under them. Betwixt each heape ſet in manner afore-
ſaid, there ought to be a foot ſpace every way, and the trench wherein they be ſet, of a ſpan depth.
Out of this plot, as out of a ſeminarie and nource-garden, theſe young plants are to be tranſlated
into another, and then they muſt be ſet two foot aſunder. Howbeit, they ought to bee above two
yeares old firſt, before they be removed and replanted. Moreover, a man may encreaſe Cheſtnut-
trees by propagation: to wit, by couching and trenching the braunches thereof, as they grow to
the mother: and there is not another tree againe that ſooner taketh that way, than it doth; for the
root thereof being laid bare, the whole braunch muſt be enterred along in the trench made for
E the purpoſe, leaving out the end onely above ground. Thus ſhall you have one tree ſpring from
it, and another from the root. Howbeit, planted in this wiſe, it loveth not to be tranſlated; it can-
not lodge elſewhere, but dreadeth and hateth all change of ſoile: and therefore ſuch plots of
ground as doe affourd coppiſes of Cheſtnut-trees, are ſtored with plants comming of marrons
or nut-kernels, rather than quick-ſets or plants ſet with the root. For the ordering and dreſſing of
them, there is no other labour required, than in the others before rehearſed; namely, for the two
firſt yeares enſuing to dig the ground looſe about their roots, and to proine or cut away the ſu-
perfluous twigs: for ever after they will ſhift well ynough, and manure themſelves, by reaſon that
their owne ſhade will kill thoſe ſuperfluous water-ſhoots that ſpring out either from the root or
the ſides of the tree. A coppiſe of theſe trees is cut ordinarily within every ſeventh yeare: and one
F acre of them will yeeld props ynough for to ſerve a vineyard of twentie acres: for beſides that
one pole of them will abide to be cloven and make two props apeece, they will laſt very well un-
till the next fall of the wood or coppis be paſt.

Moreover, the Maſt-tree called Eſculus, is planted and commeth up in like ſort: howbeit, paſ-
ſing untoward and unwilling they are to grow, and therefore they ſtand ten yeares at leaſt before

they

they be cut and lopped. Set Acornes of this tree Esculus whereſoever you pleaſe, they will ſurely take and come up: but the trench muſt be a ſpan deepe, and the Acornes two foot aſunder. And foure times in the yeare are they to be lightly *raked and cleanſed from weeds. A forke or prop made of this wood, laſteth very well and rotteth not: and in very truth, the more that the tree it ſelfe is cut and mangled, the better it ſpringeth and putteth forth new ſhoots. G

*Sarbitis.

Over and beſides theſe trees abovenamed, there bee others that uſe to be cut and lopped for Vine props and ſtaies, to wit, the Aſh, the Bay tree, the Peach, and Hazell tree, yea, and the Apple tree: but theſe are all of them lateward and ſlow of growth: neither will they endure ſo well without rotting, if they ſtand any time in the ground, and much leſſe will they abide any wet. But on the other ſide, the Elder tree of all others is moſt firme for to make poles and ſtakes of. It will grow of ſions and impes even as the Poplar. As for the Cypreſſe tree, we have of it ſpoken ſufficiently alreadie. H

Chap. xxi.

The manner and skill of husbanding and dreſsing Vineyards.

NOw that we have treated ſufficiently of the inſtruments, furniture, and tackling (as it were) belonging to Vineyards, it remaineth to ſpeake of the nature of Vines, and to deliver with eſpeciall regard the manuring and dreſſing them. According therefore as wee may ſee in Vines and ſome other trees, which have within them a ſpungeous matter and light ſubſtance, their twigs and braunches doe containe a kind of marrow or pith encloſed between certain knots or joints wherewith their ſtalkes are devided and parted. As for theſe fiſtulous concavities, they are but ſhort all of them, and toward the top ſhorter and ſhorter, but evermore betweene two knots, they encloſe the joints aforeſaid. Now this marrow, this vegetative and vitall ſubſtance, I ſay, (call it whether you will) runneth forward ſtill on end all the length of the hollow kex or pipe ſo long as it findeth no reſiſtance by the way: but meeting once with a joint or hard knot which maketh head upon it, not ſuffering the ſame to paſſe forward, it being driven backe, returneth downeward: howbeit, in that reverberation, breaketh out under thoſe knots, and putteth foorth certaine wings or pinnions like arme pits, whereas the buds or leaves doe come; but alwaies in alternative courſe, one of this ſide, and another of that; after the manner of reeds, canes, and fennell-geant, as hath been ſhewed before: in ſuch wiſe, that if one wing riſe forth at the bottome of the lower knot on the right hand, another ſpringeth for it on the left hand in that next above it; and thus they keepe order the whole length of the braunch. Theſe ſprouts when they are come once to ſome bigneſſe, and do braunch there, bee called of the Latines by a prettie name, Gemmæ, as it were precious ſtones: but ſo long, as they are no other than buds ſprouting foorth under the concavitie or pit-hole of the foreſaid joints, they tearme them Oculos, [*i.* Oilets or Eies:] marie in the very top they be named by them Germina [*i.* Sprigs or Burgeons.] After this order are engendred the maine braunches, the ſmaller *ſprigs yearely cut away, the grapes, leaves, and yong tendrils of Vines. But hereat I wonder moſt, that the burgeons comming forth on the right ſide, be alwaies more tough and firme than thoſe of the left. To come now unto the planting of theſe Vines: The ſhoots or branches muſt bee cut juſt in the middeſt betweene the foreſaid knots or joints, ſo as the marrow in no wiſe run out. And if you would plant fig-ſets or ſions, they ought verily to be a ſpan long, and then to be prickt into the ground, (but firſt there ſhould bee a hole made with a little ſtake) with the greater end that grew next to the bodie of the tree downeward; provided alwaies, that two oilets or buds ſtand above ground. Now theſe oilets are properly (in twigs or ſets of trees) thoſe buds called, where the new Spring firſt ſhooteth forth. And hereupon it is, that theſe ſions or cuttings being ſet in nource-gardens, beare the ſame yeare that very fruit which they would have borne upon the tree, if they had not been cut off: and namely, if they be ſet in the right ſeaſon whiles they be plumpe and full: for having conceived on the tree, they doe conſummate the ſad conception ſo begun, and are delivered thereof elſewhere. And looke what Fig-ſets be in this manner planted, may be eaſily and without daunger remooved and tranſlated the third yeare after. For certes, as this tree of all others ſoone ageth and endureth not long: ſo in recompence of ſhort life, this one gift it hath of Nature, That it commeth forward apace, quickly groweth to the full bigneſſe, and beareth fruit. I K L M

*Nepotes.

As for the Vine, there is not a tree that is planted more ſundrie waies, nor affourdeth greater

ſtore

A ſtore of ſions or ſets than it. For firſt and formoſt, nothing thereof is planted, but that which is unprofitable, hurtfull, ſuperfluous, and of neceſſitie to be pruned and cut away. But in the pruning, this rule muſt be obſerved, that thoſe braunches bee cut off which were portoirs and bare grapes the yeare before. The manner in old time was to plant or ſet a ſion, headed (as it were) and taking hold on both ſides of the old wood and hard ſtocke: whereupon, becauſe it was faſhioned like a little mallet or hammer head, it was and is at this day called in Latine Malleolus. But afterwards they began to ſlip off a twig with a heele onely of the old wood (as they uſe to do in a Fig-tree:) and there is not a better way to make a Vine ſurely to take and live than this. A third ſort there is beſides of ſions or ſets which are more readily gotten, without any ſuch heele of the hard wood, and therefore they be wreathed and twined when they are ſet into the ground: whereupon
B they be called in Latine Sagittæ [i. Shafts:] for the ſame ſions only cut off and not wreathed, are named Trigemmes, as a man would ſay, twigs with three buds or ſpurts. And therefore of one and the ſame Vine braunch, a man may in this ſort make many kinds of ſions or ſets. Howbeit, this is to be noted, that if you ſet any young ſprigs that never bare fruit but leaſe only, the Vines comming thereof will be ever barren: and therefore none ought to bee planted but ſuch as are fruitfull. A Vine-ſet or cutting, that hath joints ſtanding thin, but here and there, is thought to be fruitleſſe: but contrariwiſe, if it be ſet thicke with buds, by all likelyhood it will beare plentifully. Some are of opinion, that no ſions ſhould be put into the ground, but thoſe that have floured alreadie. Alſo, That to ſet ſuch cuttings as be called Shafts, which have no part of the old wood, is not ſo profitable; for that in remooving they are in danger to breake whereas they were wrythen.
C Now, when you have gotten ſuch ſets as bee meet for planting; let them be a foot long at the leaſt, and carie five or ſixe knots, and at this length they cannot poſſibly have fewer than three buds. Moreover, the beſt way is preſently to ſet them the very ſame day that they bee gathered. But in caſe a man be driven to keepe them long before they bee put into the ground, great heed would be taken, according to the rule beforeſaid, That they be not laid above ground; that they drie not in the Sunne; that they take no wind; nor looſe their freſh vigor by cold. And if it chance that they lie out any while in the drie aire, they would be laid to ſoake in water many daies together, untill they be refreſhed and looke greene againe, before they be ſet into the earth. The plot or quarter within the nource-garden or vineyard, ought to bee well expoſed to the Sunne, of a good largeneſſe, and ſufficiently moulded: alſo, it muſt be well digged for three foot broad with
D a grubbing double toothed forke: then muſt you goe deeper and caſt up the earth with a broad ſpade or ſhovell, after that the ſame hath been broken up with a mattocke or yron toole, carying foure foot in the head, ſo as the ditch may goe two foot directly deepe into the ground. Which done, the ditch is to be cleanſed, and the mould to be ſpread abroad, and not left lying raw in that manner, but to take a kind concoction in the weather. And herein muſt the labourer proceed and be ruled by meaſure, and trie his worke thereby: for if the earth be not well delved, it will be ſoone found out by the uneven balkes or beds. There would be a juſt meaſure taken alſo of the allies that lie betweene the beds. All things being thus prepared, let us come now to the planting of the ſets aforeſaid, which would be couched either in trenches made of purpoſe, or in long furrowes; and then the fineſt and moſt delicate mould that can be found, is to be caſt aloft. But all
E this prevaileth not in a leane and hungrie ground, unleſſe fatter earth bee laid as a pallet underneath. Moreover, this is to be looked unto, that two ſets at the leaſt be moulded and laid within the earth together in one range: alſo they muſt be ſo couched, that they leane with their heads cloſe upon the earth next about them: yea, and with one and the ſame ſtake the ſaid earth ought to be driven cloſe and faſt about them. Over and beſides, throughout the whole plot or quarter of this nource-garden, regard is to be had, that between every two ſets there be a foot & an halfe one way, to wit, in breadth; and halfe a foot another way, to wit, forward in length. Theſe plants being thus ordered, after they have growne to twelve months, they ſhould bee then diſcharged of all their burgeons, even to the nethermoſt knot, unleſſe haply it be ſpared and let alone: for
F ſome there be that cut it alſo. After theſe, commeth forth the matter of the oilets, and ſhew themſelves; and therewith at the third twelvemonth end the quick-ſet root and all is removed to another place in the vineyard.

Beſides all this, there is another pretie and wanton deviſe, more curious ywis than needfull, to plant Vines, and namely, after this manner. Take foure braunches of foure Vines growing together, and bearing ſundrie kinds of grapes; bind them well and ſtrongly together in that part

where

where they are most ranke and best nourished: being thus bound fast together, let them passe G
along either through the concavitie of an Oxe shanke and maribone, or else an earthen pipe or tunnell made for the nonce. Thus couch them in the ground, and cover them with earth, so as two joints or buds be seene without. By this meanes they enjoy the benefit of moisture, and take root together: and although they be cut from their owne stocke, yet they put out leaves & branches. After this, the pipe or bone aforesaid is broken, that the root may have libertie both to spread and also to gather more strength. And will you see the experience of a pretie secret? you shall have this one plant thus united of foure, to beare diverse and sundrie grapes, according to the bodies or stockes from whence they came. Yet is there one fine cast more to plant a Vine, found out but of late, and this is the manner thereof: Take a Vine-set or cutting, slit it along through the middest, and scrape out the marrow or pith very cleane; then set them together H
againe wood to wood, as they were before, and bind them fast: but take heed in any case that the buds or oilets without-forth be not hurt, nor rased at all. This done, put the same cutting into the ground, enterre it I say well within earth & dung tempered together. When it begins to spread young braunches, cut them off; and oftentimes remember to dig about it, & lay the earth light: and certes, *Columella* holdeth it for certain, and assureth us upon his word, That the grapes comming of such a Vine will have no stones or kernils at all within them. A strange thing and passing wonderfull, that the very set it selfe should live; and that which more is, grow and beare, notwithstanding the pith or marrow is taken quite away.

Furthermore, since we are entred thus farre into this discourse and argument, I cannot passe by, but I must needs speake of such twigs and braunches of trees as will knit and grow together I
even to a tree. For, certaine it is, that if you take five or sixe of the smallest sprigs of Boxe, bind them together, and so pricke them into the ground, they will proove and grow to one entire tree. Howbeit, in old time men observed, that these twigs should be broken off from a Box tree, which never had been cut or disbranched, for otherwise it was thought verily they would never live: but afterwards this was checked by experience, and the contrarie knowne. Thus much as touching the order of Vine-plants, and their nource-garden for store.

It remaineth now to speake of the manner of Vineyards and Vines themselves. Where in the first place, there offer unto us five sorts thereof. For some traine and run along upon the ground spreading every way with their braunches: others grow upright and beare up themselves without any staies. Some rest upon props, without any traile or frame at all: others be borne up with K
forkes and one single raile lying over in a long raunge: and last of all, there bee Vines that run upon trailes and frames laid over crosse-wise with foure courses of railes, in manner of a crosse dormant. The same manner of husbandrie that serveth those Vines which beare upon props without any other frame at all, will agree well ynough to that which standeth of it selfe without any staies. For surely it groweth so, for default onely and want of perches and props. As for the Vine that is led upon a single raunge as it were in one direct line, which they call Canterius, it is thought better than the other, for plentie of liquor: for besides that it shaddoweth not it selfe, it hath the furtherance & help of the Sun-shine continually to ripen the grapes: it hath the benefite also of the wind blowing through it, by which meanes the dew will not long stand upon it. Moreover, it lieth more handsome to the hand for the leaves to bee plucked away, and for the L
clods to be broken under it: & in one word, is readiest for all kind of good husbandrie to be done about it. But above all other commodities it hath this, that it is not long in the flower, but bloumeth most kindly. As for the frame aforesaid that is raunged in one line a length, it is made of perches or poles, reeds and canes, cords and ropes, or else lines of haire, as in Spaine and about Brindis. The other kind of frame with railes and spars overthwart, beareth a Vine more free for plentie of wine than the rest, and called this is *Compluviata vitis*, because it resembleth the hollow course of gutter tiles, that in houses receive all raine water and cast it off. For as the crosse dormant in building shutteth off the raine by foure gutters, even so is this Vine led and caried foure waies, upon as may trailes. Of this Vine and the manner of planting it, we will only speake, for that the same ordering will serve well ynough in every kind besides: marie there be farre more M
waies to plant this than the rest, but these three especially. The first and the surest is, to set the Vine in a plot well and throughly delved: the next to it, is in the furrow: the last of all, in a trench or ditch. As for digging a plot and planting therein, ynough hath been written alreadie.

CHAP.

A

Chap. xxii.

Of furrowes and trenches wherein vines are planted: alſo of pruning Vines.

It ſufficeth that the furrow or trench wherein a vine is to be planted, be a ſpade or ſhovels bit breadth: but ditches would be three foot long every way. Be it furrow, trench, or ditch, wherin a vine is to be replanted, it ought to bee three foot deepe; and therefore no plant thereof ſhould be remooved ſo little, but that it might over and beſides ſtand above ground, and ſhew two buds at the leaſt in ſight. Needfull it is moreover, that the earth be well looſened and made more tender and gentle, by ſmall furrows raunged and trenched in the bottome of the ditch; yea
B and to be tempered ſufficiently with dung. Now if the vineyard lie pendant upon the hanging of the hill, it requireth deeper ditches, and thoſe raiſed up well with earth and bedded, from the brims and edges on the lower ground. As for ſuch which ſhall bee made longer, and able to receive two vine-plants growing contrarie one to the other, they ſhall bee called in Latine, Alvei. Above all, the root of the vine ought to ſtand juſt in the mids of the hole or ditch; but the head and wood thereof which reſteth upon the ſound and firme ground, as neare as poſſible is, muſt beare directly into the point of the Æquinoctiall Sun-riſing: and withall, the firſt props that it leaneth upon, would be of Reeds and Canes.

As touching the bounding and limitation of a vineyard, the * principall way which runneth ſtraight Eaſt and Weſt, ought to carie eighteene foot in breadth, to the end that two carts may
C paſſe eaſily one by another, when they meet; the other croſſe allies, dividing every acre juſt in the mids, muſt be ten foot broad: but if the plot or modell of the vineyard will beare it, theſe * allies alſo which lie North and South, would be as large full as the aforeſaid principall high way. Moreover, this would bee alwaies conſidered, That vines be planted by the fives; that is to ſay, that at every fifth perch or pole that ſhoreth them up, there be a path dividing every raunge and courſe, and one bed or quarter from another. If the ground bee ſtiffe and hard, it muſt of neceſſitie be twice digged over, and therein quick-ſets onely that have taken root, muſt be replanted: marie in caſe it be a looſe mould, light, and gentle, you may ſet very cuttings and ſions from the ſtocke, either in furrow or in trench, chuſe you whether. But ſay it be a high ground and upon the hill, better it is to caſt it into furrowes overthwart, than to dig it; that by this means the pearches or
D props may keepe up the ground better, which by occaſion of raine water would ſettle downeward. When the weather is diſpoſed to raine, or the ground by nature drie, it is good planting vine-ſets or ſions at the fall of the leafe, unleſſe the conſtitution of the tract and qualitie of a countrey require the contrarie: for a drie and hot ſoile would be planted in Autumne or the fall of the leafe, whereas a moiſt and cold coaſt may tarrie, even untill the end of Spring. Let the ſoile be drie and hard, bootleſſe it will be to plant, yea though it were a very quicke-ſet, root and all. Neither will it doe well to venter the ſetting of imps cut from the tree, in a drie place, unleſſe it be immediatly upon a good ground ſhowre: but in low grounds, where a man may have water at will, there is no daunger at all to ſet vine braunches, even with leaves on the head; for they will take well enough at any time before the midſommer ſunſtead, as we may ſee by experience
E in Spaine. When you will plant a vine, chuſe a faire day; and if poſſibly you can, let it be when there is no wind ſtirring abroad; for ſuch a calme ſeaſon is beſt: and yet many are of opinion, that Southern winds be good, and they wiſh for them; which is cleane contrarie unto *Cato* his mind, who expreſſely excepteth and rejecteth them. If the ground be of a middle temperature, there ought to bee a ſpace of five foot diſtance betweene every vine: and in caſe it be a rich and fertile ſoile, there would be foure foot at leaſt from one to another; but in a leane hungrie peece of light ground, there ſhould be eight foot at the moſt: for whereas the Vmbrians and Marſians leave twentie foot void betweene every raunge of vines, they do it for to plough and ſow in the place, and therein they have quarters, beds, and ridges, called Porculeta. If the place where you plant a vineyard be ſubject to thicke and darke miſts, or to a rainie diſpoſition of the wea-
F ther, vines ought to be ſet the thinner: but in a drie quarter, it is meet they ſhould bee planted thicke. Moreover, the wit and induſtrie of man hath found out meanes to ſave charges, and in ſetting a nource-garden with vine-ſions to goe a nearer way, with ſmall expence and no loſſe of ground: for in replanting a vineyard with quicke-ſets upon a levell plot, onely digged and laid even, they have with one and the ſame labour (as it were by the way) repleniſhed the ground be-

* *Decumanæ* Lines.

* *Cardines.*

tweene every such rooted plants, with vine-cuttings for store, so as the quicksets may grow in his owne place awpointed, and the sion or cutting (which another day is to be transplanted) in the mean time take root between every course and raunge of the said vine quick-sets, before they be readie to take up much ground. Thus within the compasse of one acre, by just proportion a man may have about sixteene thousand quicke-sets. This is the difference onely, that such beare not fruit so soone by two yeare: so much later are they that be set of sions, than those that were transplanted and remaine still on foot. When a quick-set of a vine is planted in a vineyard, and hath growne one yeare, it is usually cut downe close to the earth, so as but one eye or button be left above ground, and one shore or stake must be stickt close to it for to rest upon, and dung laid well about the root. In like manner ought it to be cut the second yeare. By this meanes it gathereth strength inwardly, and maintaineth the same in such wise, as it may be sufficient another day, to beare and sustaine the burden both of braunch and bunch, when it shall be charged with them: for otherwise, if it be let alone and suffered to make hast for to beare, it would proove to be slender, vinewed, leane, and poore: for surely this is the nature of a vine, That shee groweth most willingly: in such sort, that unlesse she be kept under, chastised, and bridled in this manner, (her inordinate appetite is such) she will run her selfe out of heart, and go all to braunch and leafe.

As touching props and shores to support vines, the best (as wee have said) are those of the Oke or Olive tree; for default whereof, ye may take good stakes and forkes of Iuniper, Cypresse, Laburnium, and the Elder. As for those perches that be of other kinds, they ought to be cut and renewed every yeare. Howbeit, to lay over a frame for vines to runne upon; the best poles are of Reeds and Canes, for they will continue good five yeares, being bound many of them togither. When the shorter braunches of a vine are twisted one within another in manner of cording or ropes, and strengthned with the wood of vine-cuttings among, thereof arch-worke is made, which in Latine they call Funeta. Now by the time that a vine hath growne three yeares in the vineyard, it putteth forth apace strong braunches, which in time may make vines themselves; these mount quickly up to the frame: and then, some good husbands there be, who put out their eyes, that is to say, with a cutting-hooke (turning the edge upward) fetch off the eies budding out beneath: thus by pruning, although they seeme to doe hurt and wrong unto them, yet they draw them to shoot out the longer by the meanes: for in good faith, the more profitable way it is, thus to use and acquaint it with bearing braunches lustily; and far better and easier is it besides to cut away these young imps as the vine lieth fast joyned to the frame, untill such time as a man thinke it be strong enough of the wood. Others there are, who in no case would have a vine touched or medled withall, the next yeare after that it is remooved into the vineyard; nor yet to feele the edge of the cutting-hooke, untill it have five years over the head; mary then they agree it should be pruned & guelded of all the wood it hath, save only three burgeons. You shall have some againe that will indeed cut them the very next yeare after they be replanted, but so as they may win every yeare three or foure joynts; and when they be foure yeares old, and not before, they give them libertie to climbe upon the frame. But this (I assure you) is the next way to make the vine fructifie slowly and late: besides, it causeth it to seeme scortched and full of knots, yea and to grow like a dwarfe or wreckling. The best simply, is to suffer the stocke or mother to be strong first, and afterwards let the braunches and young imps hardly, bee as forward and audacious as they will. Neither is it safe trusting that vine which is full of cicatrises or skarres (a thing that proceedeth of great errour and an unskilfull hand;) for surely all such braunches grow of hurts or wounds, and spring not one jot from the mother-stocke indeed: for all the while that she gathereth strength, her whole vertue remaineth within her; but when she is suffered to grow and fructifie, shee goeth throughly to worke, and emploieth her forces full and whole to bring forth that, which yeerely she conceived: for Nature produceth nothing by halfes nor by peece-meale, but is delivered of all at once. Well then, after that a vine is once full grown and strong enough, let it presently run upon pearches, or bee led in a traile upon a frame; but in case it be yet with the weakest, let it be cut againe, and take up her lodging hardly beneath under the very frame: for in this point the question is not, what Age, but what Strength it hath? for that is it which must rule all. And verily great folly and rashnesse it were, to put a vine to it, and let her have the will to grow ranke, before she be as big full as a mans thumbe. The next yeare after that it is gotten to the frame, there would be saved and let to grow one or two braunches, according to the strength and abilitie of the mother: and let the same the yeare following also be preserved,

nourished,

A nouriſhed, and permitted to grow on end, unleſſe her feeblenes be againſt it: But when the third yeare is come, and not afore, be bold to give her the head with two braunches more; and never let her goe but with foure at the moſt. In one word, hold a vine downe as much as you can, never cocker and cheriſh her, but rather repreſſe her fruitfulneſſe; for of this nature is the vine, Rather than her life, ſhee would be alwaies bearing; neither taketh ſhee ſuch pleaſure to live long, as to beare much: and therefore the more you take away of her ranke and ſuperfluous wood, the better will ſhe employ her radicall ſap and moiſture to fructifie and yeeld good ſtore of grapes: yet by her good will ſhe would be ever putting forth braunches for new plants, rather than buſie in bearing fruit; for well woteth ſhe, that fruit will fall and is but tranſitorie. Thus to her owne undoing and overthrow, while ſhee thinketh to ſpread and gaine more ground, ſhee ſpends her
B ſtrength, her ſelfe and all. Howbeit in this caſe, the nature of the ſoile will guide a man and adviſe him well: In a leane and hungrie ground, although the vine be ſtrong enough, you ought to keepe it downe with cutting, that it may make abode under the head of the traile and frame above; and howſoever ſhe may have ſome hope that her young braunches ſhall get up to the top (as being at the verie point to mount above it, and ſo neare as that they reach thereunto) yet let her ſtay there and proceed no farther: ſuffer her not (I ſay) to lay her head thereupon and couch upon the traile, nor wantonly to ſpread and run on at her eaſe. In this manner (I ſay) hold her head in with the bridle, that ſhe may in the end chuſe rather to grow big in bodie and ſtrong withall, than to ſhoot forth braunches about her every way farre and neare. The ſame braunch now that is kept ſhort of the frame, ought to have two or three buds to burgen at, and to bring
C forth more wood in time: and then let it be drawne and trained cloſe unto the traile and tied faſt thereto, that it may ſeeme to beare upon it and be ſupported thereby, and not to hang looſely thereupon. Being thus bound to the frame, it muſt likewiſe be tied anon, three buds or joynts off: for by this means alſo the wood is reclaimed and repreſſed from running out in length beyond all meaſure, and the burgeons in the way between will come thicker & ſhoot up on heigth, to furniſh the husbandman with ſtore of new ſets and ſions for the next yeare. The very top end in no wiſe muſt be tied. Certes this propertie and qualitie hath the vine, That what part ſoever of it is dejected and driven downward, or els bound and tied faſt, the ſame ordinarily beareth fruit, and principally in that very place where it is bowed and bent in manner of an arch. As for the other parts which be backeward and nearer to the old maine ſtocke, they ſend out ſtore of new
D braunches indeed, full of wood, but otherwiſe fruitleſſe that yeare; by reaſon (I ſuppoſe verily) of the ſpirit or vegetative life, and that marow or pith whereof wee ſpake before, which findeth many ſtops and lets in the way. Howbeit theſe new ſhoots thus putting forth, will yeeld fruit the next yeare. Thus there offer unto us two kinds of vine braunches: for that which ſpringeth out of the hard and old wood, and promiſeth for that yeare following nothing but ſprigs and twigs onely, is called Pampinarium: whereas that which commeth more forward beyond the cut or cicatrice, and beareth ſhew of grapes, is named Fructuarium. As for another, ſpringing from a yeare-old braunch, it is left alwaies for a breeder and kept ſhort under the frame; as alſo that which they tearme Cuſtos, [i. the Keeper, or Watch:] A young braunch this is, and no longer than it may well carie three buds; which the next yeare is like to beare wood and repaire all, in
E caſe the old vine ſtocke ſhould miſcarrie and ſpend it ſelfe by carying too great a burden. Alſo another burgen there is cloſe unto him, bearing out like a knob, of the bigneſſe of a wert, (called he is Furunculus) who muſt ſerve the turne and make ſupply, if peradventure the foreſaid Watch or Keeper faile.

Moreover, a vine if it bee ſuffered to beare before the ſeventh yeare after it was firſt ſet of a cutting or ſion, decaieth ſenſibly and ſoone dieth: neither is it thought good to let the old wood run on ſtill in length upon the frame, as farre as to the fourth forke that underproppeth it, (ſuch old crooked braunches ſome call Dracones, others Iuniculos) to make thereof huge and great trailes of vines tearmed Maſculeta. But worſt of all it is, to ſeeme for to propagate or draw in a long traile within the ground vines in a vineyard, when they be growne hard with age. When
F the vine is five yeares old, a man may boldly wind and twine the very braunches, ſo as out of everie one there be a twig let to grow at libertie: thus he may proceed forward to the next, cutting away the wood as hee goeth that bare before. The ſurer way evermore is ſuppoſed to leave the Watch or Keeper behind; mary hee muſt be next unto the vine maine bodie, and neareſt the root, and no longer than is before ſet downe. Now in caſe the braunches proove over ranke,

they must be writhed and twisted in manner aforesaid, so as the vine stock may put forth no more than foure boughs at the most, or twaine if so be it rest but upon one chanter or raunge of perches. If you would order a vine so as it may stand alone without any props, at the beginning it would desire and have some supporter or other (it makes no matter what) to rest upon, untill it have learned to stand of it selfe, & rise upright: afterwards, it is to be used in manner of all other vines, when this training is past. This regard would be had in pruning and cutting the twiggs of these vines called Pollices, That a man well guide and ballance his hand, and goe even withall in every part indifferently, for feare least one side be charged with fruit or braunch more than the other: where by the way, he must also remember to keepe downe the head, and not suffer it in any wise to runne up in height: for if this kind of vine be above three foot high, it will hang the head downward. As for others, they may wel grow to five foot and upward, so that they passe not in any case the full height of a man. To come now unto the other vines that creepe along and spread over the ground; they be environed all the way as they run, with pretie short hollow cages as it were, to rest and repose their braunches in. They have need moreover of certaine trenches or ditches round about to run in, to the end that as the said braunches wander too and fro, they should not encounter one another & strive togither. And verily in most parts of the world, they use to gather their vintage of vines thus growing low by the ground: as we may see the maner is in Affricke, Ægypt, Syria, throughout all Asia, and in many places of Europe. For the good usage and dressing of these vines, a speciall care would be had to keepe them downe close to the earth; and to fortifie the root, so long and in the same manner, as hath been shewed before in those, that are shored or beare upon frames; with this charge and regard besides, to leave alwaies the short twigs only called Pollices, with three buds apeece, in case the ground be fruitfull; or * five, if it be light and leane. And in one word, better it is without all question, that they be left many, than long. As for those points which wee have delivered heretofore, as touching the nature of the soile, they will be more effectually seene to proove either the goodnesse or the contrarie, in the grapes of this vine, by how much nearer they lie to the ground, than others. Wherein, consideration is to be had of the sundrie sorts of vines, namely, that they be severed apart; and nothing is better, than to sort every one with the tract or region that agreeth best with it, and therein to plant them accordingly: for these mixtures of divers kinds are never good, but alwaies discordant: naught in old wines that come to our table, much worse then you may bee sure, in those that be new and not yet tunned up. But if a man will intermingle plants of sundrie vines togither, yet in any case those would be joyned togither (and none else) which ripen their fruit at one and the same time.

*Quinis, rather Binis, i. twaine.

For frames and trailes wherein vines are to run, the better and more battle that the ground of the vineyard is, the plainer & evener that it lyeth, the higher they would be from the ground; likewise if the place be subject to dewes, fogs, and mists, and nothing exposed to the winds: contrariwise, if the ground be leane and drie, hote, and open to the winds, they must be the lower and nearer to the earth. As concerning the rafters, that lie over and reach from prop to prop, they ought to be tied and fastened thereto with as streight and sure a knot as is possible; whereas the vine would be bound unto them, but slacke. Of the sundrie sorts of vines, as also which were to be planted in this or that soile, and what coasts and climats each one of them loveth, we have shewed sufficiently in the particular treatise of their nature, and of the wines that come of them.

Touching all other points of husbandrie that remaine behind, much doubt and divers questions are made: for many there be that feare not all Summer long to bee digging in the vineyard about vine roots, after every little raine. Others againe forbid to meddle & be lustie therin, in the budding time: for it cannot be avoided, but that the young oilets will either be smitten off cleane, or else galled and bruised one time or other, with their gate that go in and out between: which is the cause, that they would have all kind of cattell to bee kept out that they come not neare, and especially such as beare wooll on their backs; for sheepe of all others sooneſt rub off the buds as they passe by, with their shag-coats. Moreover, they are of opinion, that all manner of raking and hartowing, is an enemie to vines when they be in their flowre, and putting foorth young grapes: and sufficient it is (say they) if a vineyard be delved thrice in one yeere; to wit, first from the Spring Æquinox, to the apparition of the Brood-hen starre; secondly, at the rising of the great Dog-starre; and thirdly, when the grape beginneth to change colour and turn blacke. Others set out these times after this manner: If the vineyard be old, they would have it once dig-

ged

A ged betweene vintage and mid-winter; howſoever ſome be of this mind, That it ſufficeth them to bare the roots onely of the vines and lay dung thereto. The ſecond delving they would have to be from the Ides of Aprill, and ſix daies before the Ides of May, that is, before they begin to conceive and bud: and thirdly, before they fall to bloſſome; alſo when they have done flouring; and alſo at the time when the grapes alter their hew. But the more skilfull and expert husbands affirme conſtantly, That if the ground be overmuch laboured, and digged too often, the grapes will be ſo tender skinned, that they will burſt againe. Moreover, theſe rules following are to bee obſerved, That when any vines do require ſuch delving and digging, the labourers ought to go to worke betimes before the heat of the day: marie if the vineyard ſtand upon a myrie clay, it is not good then either to eare or dig it, but rather to wait for the hot ſeaſon; for the duſt that ri-
B ſeth by digging, is very good (by their ſaying) both to preſerve the vine and grapes from the partching ſunne, and alſo to defend them againſt the dropping miſts.

As for disburgening of vines and cleanſing them of their ſuperfluous leaves, all men accord, that it ſhould be done once in the Spring, to wit, after the Ides of May, for the ſpace of eleven daies following; and in any hand before they begin to put forth flower. And how much thereof muſt be thus diſſoiled for the firſt time? even all that is under the traile or frame, and no more. As for the ſecond, men be not all of one mind; Some would have the leaves to be disbraunched when the vine hath done flowring: others expect, untill the grapes begin to be ripe. But as touching theſe points, the rules that *Cato* giveth, will reſolve us: for wee are now alſo to ſhew the manner of cutting and pruning vines. Many men begin this worke immediatly after vintage,
C when the weather is warme and temperate: but in deed (by courſe of Nature) this ſhould never be done before the riſing of the Ægle ſtarre (as we will more at large declare in the next booke; where we are to treat of the riſing and fall of the fixed ſtars and of their influences;) or rather in truth, when the Weſterne wind Favonius beginneth to blow, foraſmuch as there might be daunger in going over ſoone to worke, conſidering that haſt commonly maketh waſt. For this is certaine, that if there come an after-winter, and chaunce to bite the vines newly medicined (as it were) or rather ſore with this pruning, if it happen (I ſay) that when every man makes reckoning that winter is gone, it come upon them againe and whiske with his taile, their buds pinched with cold will looſe their vigor, their wounds will cleave and make rifts, in ſuch ſort, that when the humiditie is diſtilled and dropped forth, the oilets will be nipt and burnt away with the bitter-
D neſſe of the unſeaſonable weather: for who knoweth not, that in froſt it is tickliſh medling with vines, and that they be in daunger ſoone to breake and knap aſunder? To ſay therefore a truth, by order of Nature there would not be ſuch haſt made. But here is the matter, they that have a large domaine and much lands to looke unto, they that muſt go through a great deale of worke, cannot will nor chuſe but begin betimes, and make this computation and reckoning aforeſaid. And in one word, the ſooner that vines be pruned (if the time will ſerve commodiouſly) the more they run into wood and leaves; and contrariwiſe, the later you go to worke, the more plentie of grapes they will yeeld: and therfore it is meet and expedient to prune vines that bee poore and feeble, very timely; but ſuch as bee ſtrong and hardie, laſt of all.

As for the maner and faſhion of the cut, it ought alwaies to be aſlaunt, like a goats foot, that
E no drops of raine may ſettle and reſt thereupon, but that every ſhowre may ſoon ſhoot off: alſo that it turne downward to the ground, that it be even and ſmooth made with a keen and ſharpe edged bill or cutting hooke. Furthermore, this heed would be taken, that the cut be juſt between two buds, for feare of wounding any of the oylets neere unto that part which is cut off: and commonly this is ſuppoſed to be black and duskiſh, and ſo long as it is ſo ſeene, it ought to be cut and cut againe, untill you come to that which is ſound and cleere indeed: for never ſhall yee have out of a faulty and corrupt wood, any thing come forth that will be worth ought. If the vine be ſo poore and leane that it affordeth no branches meet and ſufficient to beare, cut it down to the very ground, for beſt it is then to fetch new from the root, and to ſee whether they will be more lviely. Over and beſide in disburgening and defoiling a vine, you muſt beware how
F you pluck off thoſe burgeons that are like to beare the grape, or to go with it; for that were the next way to ſupplant (as it were) the grapes, yea and kill the vine, unleſſe it were a new and young plant. Will you then know which are unprofitable and may be ſpared? even all thoſe are deemed ſuperfluous, which come not directly from the knot or neere the oilet, but grow out of the ſide: and no marvaile, ſince that the very branches of grapes which hang in this maner out of

the hard wood, are so stiffe and tough also that unneth a man may plucke them off with his fingers, but had need of a knife or hooke to cut them away. G

As for the pitching of props into the ground, some are of opinion, that the best way is to set them between two vines: and in deed that were the easier way to come about the vines, for to lay their roots bare when time serveth. Also, better is it farre so to doe, in a vineyard where the vines run upon one single traile, in case the said traile be strong enough, and the vineyard not subject to the daunger of winds: but where a vine runneth foure waies, it must be relieved with prop and staies as neare as may be, to support the burden; yet so, as they bee no hinderance when as men should come about the foot to lay the root bare: and therefore they would be a cubit off, and no more. Moreover, this is a generall rule, that a vine be cleansed about the root beneath, before that it be pruned above. H

Cato treating generally of all matters concerning vines, writeth thus by way of rule and precept: Let your vine (quoth he) be as high as possibly you can: fasten it to the frame decently, but take heed you bind it not too hard. Dresse and order it after this maner: After you have cut away the tips and tops thereof, dig round about the rootes, and begin then to eare up and plow the vineyard: draw furrows and ridges too and fro throughout. Whiles vines be yong and tender, couch their branches within the ground for propagation, with all speed: as for old vines, gueld them as little as you can, & keep them with a good head; rather if need require, lay them along on the ground, and two yeeres after cut them hard to the root. If it be a young vine, attend untill it be of strength sufficient; then will it be time and not afore to cut and prune it. If haply the vineyard be bare and naked of vines, and that they grow but thin here and there, make furrowes I and trenches between, and therein plant new quicksets: but rid the weeds well from about those trenches, for overshadowing them: be ever also digging and delving. Then, if it be an old vineyard, sow drage and pulse for provender: if it be a leane and light ground, sow nothing that beareth graine or corne. Be sure that ye lay about the heads of the said quicksets, dung, chaffe, refuse of grapes pressed, & such like mullocke. When the vine beginneth to put out leaves & looke green, fall to disburgeoning. So long as the vines be young and tender, tie them surely in many places, for feare lest the wood or stalke therof doe breake asunder. But when a vine hath gotten head to perch aloft upon a single traile, gently bind the tender burgeons & branches thereof, extend and stretch them out, & lay them streight. Now when they stand once upright & are able to beare themselves, marke when the grapes begin to change colour, bind them well & sure below. K

As for graffing of vines, there are two seasons of the year meet therfore: the one in the spring, the other when the vine doth flower; and this is held for the best. If you purpose to translate an old stocke of a vine into another place, and there to replant it, cut off the first thicke arme only; leaving behind two buds and no more. In taking of it up, bee carefull that you doe it with such dexteritie, as that you rase not nor wound the root. This done, looke how it grew before, so set it now, either in trench or furrow: couch it well and close, and cover it throughly with good mould. After the same manner as is beforesaid, under-set and prop it up, bind it, turne and wind it; but above all, be every while digging about it. As touching the drage called Ocynium, which *Cato* willeth to be sowed in a vineyard, it is a kind of forage or provender for horses, which the Latins in old time named Pabulum: it commeth up very speedily and groweth fast, and besides can well L away with shadowie places.

Chap. xxiii.

Of trees raunged in rewes, for to support Vines.

IT remaineth now in this discourse and treatise of Vines, to write of the manner of trees planted of purpose for to serue their turne. And here I cannot chuse but call to minde, first, how this point of husbandry hath been judged naught, and altogether condemned by the two *Sarsennæ*, both father and sonne; but contrariwise held for good, and highly commended by *Scrofa*: whereas, all three were reputed the most ancient writers, and skilfullest in this kind, next M to *Cato*. And yet *Scrofa*, as great a patron as he is thereof, alloweth not this devise in any climate els, but only in Italy. Howbeit, gone this hath for currant many yeeres past, and time out of mind, That the best and most dainty wines came of those grapes only which grew upon such Hautins or trees beforesaid. Yea, and it was thought generally that the higher a vine climbed upon

A on theſe trees, the better grapes it bare, and yeelded more commendable wine: and againe, the lower that thoſe trees were, the greater plentie followed both of the one and the other. By which a man may ſee how materiall it is to raiſe Vines on high, and have grapes growing in the top of trees. In which regard, choiſe alſo is to bee made of trees for this purpoſe. And here firſt and formoſt is preſented unto us the Elme: and yet I muſt except that kind of it which is called Atinia, by reaſon that it is overmuch charged with boughes and leaves, and therewith too full of ſhade. Next unto it may bee raunged the blacke Poplar, even for the ſame cauſe, becauſe it is not leaved nor branched ſo thicke. Many men there be that refuſe not the Aſh, the Fig tree, yea and the Olive, ſo that it ſtand not over thicke with boughs, and make too much ſhade. As touching the ſetting, planting, and ordering of theſe trees in generall, wee have ſufficiently and to the full treated
B heretofore. But now for this ſpeciall and peculiar uſe that they be put unto, this would be conſidered, That Vines which are to be wedded to theſe trees, muſt in no wiſe feele the edge of the cutting hooke, before they bee three yeares old full. After which time, this regard ought to bee had, that every ſecond branch or arme thereof is to be ſpared: and likewiſe each other yeare and no oftener they are in this wiſe to bee pruned: and by that they are ſix yeares old, it is good time to joine them in mariage unto their husbands aforeſaid.

In Piemont, Lumbardie, and thoſe parts of Italie beyond the river Po, they uſe for this purpoſe to plant their grounds with theſe trees over and beſides thoſe beforenamed, to wit, the Cornell, the Opiet or Wich-hazell, the Teil or Linden, the wild Aſh Ornus, the Carpin Carme or Horn-beame, and the Oke. About Venice and all that tract, the Willowes ſerve the turne & none
C elſe, by reaſon that the whole ſoyle ſtandeth ſo much upon water.

As touching the Elme, named in the firſt place, it muſt be kept plaine and bare, and the great water-boughs underneath ſhred untill you come to the middeſt of the tree, or thereabout: and then the reſt ought to bee arraunged and digeſted into good order, whereupon the Vine may climbe as it were upon ſtaires or ladder rounds: and lightly none of theſe trees upward be above twentie foot high. Now in caſe it be a high ground upon an hill, and drie, they are permitted to braunch and ſhut out their armes, within eight foot of the ground. But in plaines and low moiſt grounds, they begin not to forke before they beare twelve foot. Howbeit, let the place be what it will, the flat of the tree from whence the boughs begin to devide, ought to regard the South ſun. And the ſaid branches immediatly from their project muſt riſe ſomewhat upright in manner of
D fingers, ſtanding forth from the palm of ones hand: among which, the ſmall ſprigs muſt eftſoons be barbed (as it were) and ſhaven cleane off, for feare they doe not overſhade the Vine branches.

As touching the ſpace or diſtance betweene one tree and another, the ordinarie proportion is, that afront and behind, in caſe the ground bee erable, it beare fortie foot: but a flanke, or on the ſide, twentie. Marie, if it be not well tilled and husbanded, ſo much will ſerve every way, to wit, twentie foot and no more. Commonly every one of theſe trees maintaineth tenne Vines at the foot thereof: and a bad husband he is who hath fewer reared about it than three. But by the way, it is no good husbandrie to ſuffer a tree thus to bee coupled (as it were) in marriage to ſo many Vines, before that it bee of ſufficient ſtrength to entertaine them: for there is nothing ſo hurtfull, by reaſon that the Vines will choke and kill them; ſo quicke they bee of their growth, and ſo
E readie to overcharge them.

As for planting of Vine-ſets to the root of trees, needfull it is to make therefore a ditch three foot deep: and they ought to be diſtant one from the other a full foot, and ſo much likewiſe from the tree. This done, there is no queſtion there of the ſmall twigs or ſhoots what to do with them? neither is there any charge or expence required for digging and delving: for this is the manner of it, and this peculiar gift have theſe tree-rowes, That in the ſame ground where they grow, the ſowing of corne is nothing hurtfull, nay, it is profitable and good for the Vines. Moreover, this commoditie and eaſement commeth of their height, that they bee able to ſave themſelves: neither is there any ſuch need, as in other Vineyards, to be at the coaſt of walls, of mounds, pales, or hedges, ne yet of deepe ditches or other fences, to keepe off the violence or injuries of beaſts. Of
F all other toiles before rehearſed, there is no more required but to looke unto onely the getting of quick-ſets, or couching ſions: all the matter I ſay lieth herein, and there is no more to do.

But of couching ſions and that kind of propagation, there bee two deviſes. Firſt within paniers or baskets upon the boughs of the tree, and that is the beſt way, becauſe it is ſafeſt from the daunger of cattell. The ſecond is, to bend the Vine, or a branch thereof, cloſe to the foot of her

owne

owne tree, or else about the next unto it: if it stand single and have no Vine joined unto it. As much of this branch or Vine thus couched as is above the ground, must be kept with scraping; that is to say, the buds ought ever and anone to be knapt off, that it spring not forth. Within the earth there should bee no fewer than foure joints or budding knots buried and enterred for to take root; in the head without, two onely are left for to grow. [Where, note by the way, that the Vine which groweth to the foot of a tree, must be trenched in a ditch foure foot long in all, three in breadth, two and an halfe in deapth.] Now, when the sion thus couched, hath lien one yeare, the order is to cut it toward the stock to the very pith or marrow, that so by little and little it may be inured to fortifie it selfe upon the owne roots, and not to hang and cling alwaies to the mother: as for the other end or head thereof, it would bee cut off also so neare the ground, as that there be but two onely buds left. By the third yeare it must bee quite cut in two, (where before it was but guelded to the pith) and that which remaineth of it, laid deeper into the ground, for feare it should sprout foorth and beare leaves toward that side where it was cut in twaine. This done, no sooner is Vintage past, but this new quicke-set, root and all, must bee taken up and replanted.

Of late daies devised was the manner of couching or planting by a trees side a Vine Dragon (for so we use to call the old braunch of a Vine past all service, which hath done bearing many a yeare, and is now growne to be hard.) And verily, they use to make choise of the biggest they can find, which when they have cut from the stocke, they scrape and pill the barke three foure parts in length, so farre forth as it is to lie within the ground [whereupon they name it in Latine Rasilis:] when it is thus couched low within a furrow, the rest that is above the earth they reare up against the tree. And it is thought, that there is not so good nor so readie a mean to make a Vine grow and beare than this. If it fall out so, that either the Vine be small and weake, or the ground it selfe but leane and hungrie, it is an usuall and ordinarie practise to cut and prune it as near the ground as possibly may bee, untill such time as it bee well strengthened in the root: as also, great regard is had, that it bee not planted when the deaw standeth upon it, ne yet when the wind sits full in the North. The old Vine stocke it selfe ought to look into the Northeast, provided alwaies that the young braunches turne Southward. Moreover, new and tender Vines would not be proined and cut in hast: but better it is to expect and tarie untill such time as they be strong ynough and able to beare the cutting bill: meane while, to gather the young braunches together round in manner of an houpe or circle. [Where note by the way, That Vines which are erected upon trees, for the most part beare later by one yeare than those in Vineyards that bee perched or run on frames.] Some would not have them to be cut at all, before they have raught up to the top of the tree. At the first time when you come with the pruning hooke, the head must be cut off at six foot from the ground, leaving underneath one little top twig, which must bee forced to beare by bending it downeward in the head: and in the same, when it is thus pruned, there must bee left behind three buds and no more. The braunches which burgen out from thence, ought the next yeare to bee brought up to the lowest armes of the tree, and there seated: and so from yeare to yeare, let them climbe up higher to the upper boughs, leaving alwaies upon every loft or scaffold as it were where they rested, one braunch of the old hard wood, and another young imp or twig, for to grow up and climbe as high as it will. Furthermore, as often as a Vine is pruined afterwards, those braunches or boughes thereof in any wise must be cut away which were bearers the yeare before: and in stead of them, the new after they be first cleansed from all the hairie & curled tendrils on every side shred off. The ordinarie manner of pruning and dressing of vines here about Rome, is to let the tender braunches and sprigs enterlace the boughes, insomuch, as the whole tree is overspread and clad therewith, like as the very same tendrils be also covered all over with grapes. But the French fashion is to draw them in a traile along from bough to bough: whereas in Lumbardie and along the causey Æmylia [from Plaisance to Rimino] they use to traine them upon forkes and poles: for albeit the Atinian Elmes bee planted round about, yet the vine commeth not neare their greene boughs. Some there be, who for want of skill and good knowledge about vines, hang them by a strong bond under the boughs: but this is to wrong, yea to stifle and strangle them outright: whereas indeed a vine, as it ought to be kept downe with oisier twigs, so it must not be tied over streight. For which cause, even they also who otherwise have store and plentie ynough even to spare, of Willowes and Oisiers, yet chuse rather to bind vines with some more soft and gentle matter, to wit, with a certaine hearbe, which the Sicilians in their

language

A language call Ampelodeſmos, [*i.* Vine-bind.] But throughout all Greece they tie their Vines with Ruſhes, Cyperus, or Gladon, Reeke, and ſea-graſſe. Over and beſides, the manner is otherwhiles to untie the Vine, and for certaine daies together to give it libertie for to wander looſely; and to ſpread it ſelfe out of order, yea, and to lie at eaſe along the ground, which all the yeare beſides it only beheld from on high: in which repoſe it ſeemeth to take no ſmall contentment and refreſhing; for like as draught horſes, when they be out of their geeres, and hackneis unſaddled, like as Oxen when they have drawne in the yoke, yea, and greyhounds after they have runne in chaſe, love to tumble themſelves and wallow upon the earth; even ſo the Vine alſo, having been long tied up and reſtrained, liketh well now to ſtretch out her lims and loines, and ſuch eaſement and relaxation doth her much good. Nay, the tree it ſelfe findeth ſome comfort and joy thereby,
B in being diſcharged of that burden which it carried continually as it were upon the ſhoulders, and ſeemeth now to take breath and heart againe. And certes, go through the whole courſe and worke of Nature, there is nothing, but by imitation of day and night, deſireth to have ſome alternative eaſe and play-daies betweene. And it is by experience found very hurtfull, and therfore not allowed of, to prune and cut Vines preſently upon the Vintage or Grape-gathering, whiles they be ſtill wearie and over-travelled with bearing their fruit ſo lately: ne yet to bind them (thus pruned) in the ſame place againe, where they were tied the yeare before: for ſurely Vines do feele the very prints and markes which the bonds made, and no doubt are vexed and put to pain therwith, and the worſe for them.

The manner of the Gaules in Lumbardie, in training of Vines from tree to tree, is to take two
C boughs or braunches of both ſides, and draw them over, in caſe the ſtocke Vines that bear them bee fortie foot aſunder: but foure, if they are but twentie foot diſtant. And theſe meet one with another in the ſpace betweene, and are interlaced, twiſted, and tied together: but where they are ſomewhat weake and feeble, they bee ſtrengthened with Oiſier twigs or ſuch like rods here and there by the way, untill they beare out ſtiffe: and looke where they bee ſo ſhort that they will not reach out, they are with an hooke ſtretched and brought to the next tree that ſtandeth without a Vine coupled thereto.

A vine braunch drawne thus along in a traile, they were woont to cut when it had growne two yeares. For in ſuch vine-ſtockes as by reaſon of age bee charged with wood, it is the better way to
D give time and leaſure for to grow and fortifie the ſaid braunch that is to paſſe from tree to tree, ſo as the thickneſſe thereof will give leave: yea, and otherwiſe it is good for the old maine bough to feed ſtill and thrive in pulpe and carnoſitie, if wee purpoſe that it ſhould remaine and carie a length with it.

Yet is there one manner beſides of planting & maintaining Vines, of a mean or middle nature betweene couching or enterring a braunch (by way of propagation,) and drawing them thus in a traile from one to another: namely, to ſupplant, that is, lay along upon the ground the whole ſtocke or maine bodie of a Vine; which done, to cleave it with wedges, and ſo to couch in many furrowes or raies, as many parcels thereof, comming all together from one. Now in caſe ech one of theſe braunches or armes proceeding from one bodie, bee of it ſelfe ſmall, weake, and tender,
E they muſt bee ſtrengthened with long rods like ſtaves bound unto them round about; neither ought the ſmall ſprigs and twigs that ſpring out of the ſide, be cut away.

The husbandmen of Novaria reſt not contented with a number of theſe trailed braunches, nor with ſtore of boughs and trees to ſuſtaine and beare them, unleſſe they be ſhored & ſupported alſo with poſts and overthwart railes, about which the young tendrils may creepe and wind. No marvell therefore if their wines bee after a ſort rough, hard, and unpleaſant: for beſides the badneſſe of their ſoile, the manner of their husbandrie is ſo crooked and untoward.

Our husbandmen moreover here about us (neare unto the citie of Rome) commit the like fault, and find the ſame defect thereupon, in the Varracine Vines, that bee pruned but once in two yeares: a peece of husbandrie by them practiſed, not for any good that it dooth unto the Vine, but becauſe the wine thereof is ſo cheape, that oftener pruning would not quit coſt; nei-
F ther doth the revenue anſwere the labour and the charges.

In the territorie of Carſeoli (a champion and plaine countrey about Rome) the peaſants take a better order, and hold a middle and temperate courſe. For their manner is to proine and cut away from the Vine thoſe parts onely that are faultie and rotten, when they begin once to be drie and to wither, leaving all the reſt for to beare grapes: and thus diſcharging it of the ſuperfluous

burden

burden that it caried, they hold opinion, that it is not good to wound it in many places: for by this meanes (say they) it will be nourished and come on very well. But by their leave, unlesse the ground be passing rich and fat, Vines thus overcharged with wood, will for want of pruning degenerate into the bastard wild wines called Labruscæ. G

But to returne againe unto our plots planted with Trees and Vines coupled together: such grounds when they be ploughed, require a good deepe stitch, although the corne therin sowne need it not. Also it is not the manner to disburgen or deffoile altogether such trees, and thereby a great deale of toile and labour is saved: but when the Vines are a pruning, they would bee disbraunched at once with them, where the boughes grow thickest; and to make a glade onely through, the superfluous branches would bee cut away, which otherwise might consume the nutriment of the grape. As for the cuts and wounds remaining after such pruning and disbraunching, we have alreadie forbidden, that they should stand either against the North or the South. And I thinke moreover it were very well, that they did not regard the West where the Sun serteth: for such wounds will smart and be long sore, yea, and hardly heale againe, if either extreame cold pinch, or excessive heat parch them. H

Furthermore, a Vine hath not the same libertie in a Vineyard that it hath upon a tree: for better meanes there are, and easier it is to hide the said wounds from the weather flanked as they be within those close sides; than to wryth and wrest them to a mans mind too and fro. In lopping and shredding of trees, when the cut standeth open, there would be no hollow places made like cups, for feare that water should stand therein. Last of all, if a Vine bee to climbe trees that are of any great height, there would bee staies and appuies set to it, whereupon it may take hold, and so by little and little arise and mount up aloft. I

Chap. xxiiii.

The manner of keeping and preserving grapes. Also the maladies whereto trees be subject.

IT is holden for a rule, That the best Vine-plants which run upon a frame of railes, ought to be pruned in mid-March about the feast of *Minerva*, called Quinquatrus: and if a man would preserve and keepe their grapes, it would bee done in the wane of the Moone. Also, that such Vines as be cut in the change of the Moone will not be subject to the injurie and hurt of any noisome vermine. Although in some other respect, men are of opinion, that they should bee cut in the night, at the full of the Moone, when the signe is in Leo, Scorpio, Sagittarius, and Taurus: and generally it is thought good to set them when the Moon is at the full, or at leastwise when she is croisant. Moreover, this is to be noted, that in Italie there need not above ten men for to looke unto a Vineyard of a hundred acres. K

And now that I have discoursed at large as touching the manner of planting, graffing, and dressing of trees, I purpose not here to treat againe of Date-trees and Tretrifolie, whereof I have alreadie sufficiently written in the Treatise of straunge and forraine trees: but for as much as my meaning is to omit nothing, I will proceed forward to decipher those matters which concern principally the nature of trees, and namely, their maladies and imperfections; whereto they also as well as beasts and other living creatures, be subject. And to say a truth, what creature is there under heaven freed therefrom? And yet some say, that wild and savage trees are in no such daunger: onely the haile may hurt them in their budding and blouming time. True it is moreover, that scorched they may be otherwhiles with heat, and bitten with cold blacke winds, comming late and out of season: for cold weather surely in due time is kindly and good for them, as hath been said before. But let me not forget my selfe. See wee not many times the cold frost to kill the very Vines? Yes verily; but this is long of the soile and nothing else: for never happeneth this accident but in a cold ground. So as this conclusion holdeth still, That in Winter time wee alwaies find frost and cold weather to doe much good: but wee never allow of a cold and wealie ground. Moreover, it is never seene, that the weakest and smallest trees are endaungered by frost, but they are the greatest and tallest that feele the smart. And therefore no marvell if in such, the tops being nipped therewith, seeme first to fade and wither; by reason that the native and radicall moisture being bitten and dulled before, was never able to reach up thither. L M

Now, concerning the diseases that haunt trees: some there bee that are common unto all,

others

A others againe,that extend peculiarly to ſome certaine kind or other. As for the former ſort,generall it is,that no trees are exempt from the worme, the blaſting,and the joint-ach. Hereof it commeth,that we ſee them more feeble and weake in one part or member than in another; as if they did participate the maladies and miſeries of mankind,ſo common are the names of diſeaſes unto them both.For certes,we uſe to ſay indifferently,That trees are headleſſe,when they be lopt and topt,as well as men who are beheaded: wee tearme their eies to bee enflamed,ſendged,and bloud-ſhotten, when their buds be blaſted:& many other infirmities, according to the like proportion.And thereupon it is,that we ſay they be hungerſtarved and pined: and contrariwiſe,that they be full of crudites and raw undigeſted humors; namely,when moiſture aboundeth in them. Yea,and ſome of them are ſaid to be groſſe and overfat,to wit,all ſuch as bear roſin; when by the
B meanes of too much greaſe(as it were) they begin to putrifie and turne into Torch-wood: yea, and it falleth out,that they die withall,in caſe the ſaid greaſe take once to the roots; even as living creatures being overgrowne with fat. Moreover, yee ſhall ſee a kind of peſtilence light amongſt one peculiar kind of trees: like as it fareth ſometimes with men in ſundrie ſtates and degrees: whereby one while ſlaves only die of a plague,another while the Commons,and thoſe either artiſans in a citie,or peaſants and husbandmen of the countrey.

Now as touching the Worme, ſome trees are more ſubject unto it than others: and to ſay a truth,in manner all,more or leſſe; and that,the birds know well ynough, for with their bils they will job upon the barke,and by the ſound trie whether they be worme-eaten or no. But what ſay wee to our gluttons and belli-gods in theſe daies,who make reckoning among their daintie di-
C ſhes of worms breeding in trees; and principally of thoſe great fat ones bred in Okes, which wormes they call Coſſi,and are eſteemed a moſt delicat meat? Theſe forſooth they feed in mue, and franke them up like fat-ware,with good corne-meale.But above all others,Peare trees,Apple trees,and Fig trees,are ſooneſt worme-eaten: and if any trees eſcape,they be ſuch as are of a bitter wood in taſt,and odoriferous in ſmell.Touching thoſe worms that be found in Fig trees,ſome are engendred of themſelves,and of the very wood: others are bred of a bigger vermine called Ceraſtes.Howbeit,all of them(which way ſoever they come)are ſhaped in manner of the ſaid Ceraſtes, and make a certaine ſmall noiſe like the ſhrill and creaking ſound of a little criquet. The Serviſe tree likewiſe is haunted and plagued with little red and hairie wormes, which in the end doe kill it.The Medlar trees alſo when they be old,are ſubject to this maladie.

D As for the miſliking of trees [called Sideratio]wherby they conſume,wither away,and crumble to powder; it is a thing cauſed onely of the weather and influence of ſome Planet. And therefore in this ranke are to be raunged Haile, Blaſting with ſome untoward winds,and Froſts which bite and nip them to the heart. And verily it falleth out, that in a mild and warme Spring,when plants bee too forward and put foorth their ſoft buds and tender ſprouts over-ſoone, the blacke wind taketh them on a ſuddaine,and a certaine rime ſettleth thereupon, ſendging and burning the oilets of the Burgeons,whiles they be full of a milkie ſap: which accident, if it light in blooming time upon the bloſſome,is called properly Carbunculus[*i.*a Mieldeaw.]As for the Froſt at ſuch a time,it is far worſe than the blaſting aforeſaid: for when it falleth upon any trees or plants, it there reſteth and remaineth ſtill,it congealeth all into an yce, and no puffe of wind there is to
E remove and diſlodge it: for why? ſuch froſts commonly are not but in time of a ſtill, cleare, and calme aire. Touching that manner of Blaſting or miſliking called Sideratio, as if they were ſmitten with the maligne aſpect of ſome planet,this daunger chaunceth peculiarly by ſome drie and hote winds,which are buſie commonly about the riſing of the Dog ſtar,at what time we ſhall ſee young trees and newly graffed,to die outright,eſpecially Figge trees and Vines. The Olive,over and beſides the worme(whereto it is ſubject as well as the Figge tree)hath another greeſe and ſorance called in Latin Clavus,Fungus or Patella [*i.*a Knur,Puffe,Meazil or Bliſter]chuſe you whether: and nothing is it but a very ſendge or burne by the Sunne.

Furthermore,*Cato* ſaith,That the red moſſe is hurtfull unto trees.Oftentimes alſo we find that as well Olives as Vines,take harme by overmuch fertilitie and fruitfulnes. As for ſcab and skurfe,
F what tree is cleare of it? The running mange or tettar, is a miſcheefe peculiar unto the Fig tree: as alſo,to breed certaine Hoddy-dods or ſhell-Snailes ſticking hard thereto and eating it. And yet theſe maladies are not indifferent and alike in all parts of the tree. For thus you muſt thinke, that ſome diſeaſes are appropriate to one place more than another. For like as men are troubled with the Arthriticall torments, or the Gout; even ſo be trees: yea,& after two ſorts as well as they.

they: for either doth the disease take the way to the feet, that is to say, to the roots, and there breaketh out and sheweth it selfe; or els it runneth to the exteriour joynts and fingers, to wit; the small branches and top twigs, which be fartheſt remote from the maine bodie of the tree. Hereupon then begin they to drie, wither, and wax blacke: and verily the Greekes have proper names and tearmes respective to the one infirmitie and the other, which we in Latine want. Howbeit we are in some sort able to expresse the Symptomes following thereupon; and namely, when we say, first, That a tree is ill at ease, sicke, and in paine every where: anon, that it falls away, lookes ill, poore, and leane, when we see the fresh greene hew gone, and the braunches fraile and brittle: last of all, that it is in a wast, consumption, or fever hecticke, and dieth sensibly, to wit, when it receiveth no nourishment (or not sufficient) to reach unto all parts, and furnish them accordingly: and tame Figge trees of all others, are most subject hereunto; as for the wild, they be exempt wholly from all these inconveniences hitherto named.

Now as touching the scab or scurfe incident unto trees, it commeth of certaine foggie mists and clammie dewes, which light softly and leisurely after the rising of the Brood-hen starre Vergiliæ: for if they be thin and subtile, they drench and wash the trees well, and do not infect them with the scab: howbeit in case they fall downe right, or that there be an over great glut of showers and raine, the Fig tree taketh harme another way, namely, by soking of too much moisture into the root.

Vines, over and above the Worme and the Blast, have a disease proper unto themselves, called Articulatio, which is a certain barrennesse of theirs when they leese their spring in the verie joynt. And this may come upon three causes: the first, when by unseasonable and ill weather, as frost, heat, haile, or other forcible impressions of the aire, they forgoe their young sprouts: the second, (as *Theophrastus* hath well noted) if in pruning of them, the cut stand upward and open to the weather: the third, when they be hurt by those that have the dressing of them, for want of skill and taking good heed: for all these wrongs and inconveniences they feele in their joynts or knots. A severall kind of blasting or mortification there is besides in vines, after they have done blooming, which is called Roratio; namely, when either the grapes doe fall off, or before they come to their full growth, be baked (as it were) into a thicke and hard callositie. It happeneth also that they be otherwhiles sicke, in case after their pruning, their tender oilets or buds be either bitten with the frost, or sindged with some blast. The same befalleth likewise unto them upon some untimely or unseasonable heat: for surely in all things, a certaine measure and moderate temperature doth well, to bring them to their perfection. To say nothing of the wrong that is done unto them by the vine-masters themselves and husbandmen as they dresse and trim them, namely, when they bind them over-streight, as hath been said before; or when the labourer that diggeth about them, chaunceth to doe them one shrewd turne or other by some crooked crosse blow; or else when the ploughman at unawares doth loosen the root, or glaunce upon it with the share, and so disbarke the bodie of it: finally, they have injurie done unto them, in case the pruning-hooke be over blunt, and so give them a bruise. In regard of all these causes, they are lesse able to beare either cold or heat; for every outward injurie is readie to pierce their fresh galls, and a scald head is soone broken. But the tendereſt and weakeſt of all others, be the Apple trees, and namely, the hastie kind that bringeth sweet Iennitings. Howbeit some trees there be, which upon such feebleneſſe and hurt done unto them, become barren only, & die not; namely, the Pine and Date tree: for if a man fetch off their heads, you shall see them faile in bearing fruit, but this hurt will not kill them quite.

Moreover, it falleth out otherwhiles, that the Apples onely or other such fruits, as they hang, are diseased, when as the tree aileth nothing; to wit, if in due time they wanted raine, warmth, or winds that were needfull; or contrariwise, if they had too much of every one: for by such means they either fall from the tree of themselves, or els they are the worse for it, if they proove worth ought at all.

The greateſt displeasure that can happen to Vine or Olive tree, is, when in their very blooming they be pelted with violent showers of raine; for, togither with the blossome, downe goeth the fruit of them both. From the same cause, proceed the cankerwormes or caterpillers (a most daungerous and hurtfull kind of vermine to trees) which will eat out the greene bud, knot and all. Others there be that will devoure the blossome and leafe of Olives also, as in Miletum: and thus having consumed all the greene leaves, leave the trees bare, naked, and ill-favoured to the eye.

A eye. These wormes doe breed in moist and warme weather, and specially if there be thicke and foggie mists. Of the same vermine, there is another engendred, namely, if there ensue upon the former wet season, hoter gleames of the sunne more than ordinarie, which burne the foresaid wormes, and therefore chaunge them into other vermine. Moreover, there is a fault or imperfection besides, wherto Olives and Vines especially are subject, and this they call in Latine Araneus, [*i.* the Spider] when cobwebs (as it were) doe enfold and wrap their fruit, keeping them from growing, and so in time killing them. Over and besides, there bee certaine winds which sindge and burne Olives and grapes principally, yea and all sorts of fruits whatsoever. In some yeares also ye shall see all fruits worm-eaten, and especially Apples, Peares, Medlars, and Pomegranats, without any such hurt and offence to the trees that beare them. As for Olives, the worme
B sometimes doth them harme, otherwhiles good: for if the worme bee engendred and formed before it take the Olive, it consumeth and spoileth the fruit; but in case they breed within the kernel, it causeth the Olive to thrive the better, by eating the said kernell that drew away and sucked the humour which nourished it. The raine that falleth after the rising of the starre Arcturus, hindereth the generation of wormes, and preserveth fruits from beeing worme-eaten: and yet if the wind sit Southward in that time when it so raineth, such raines will breed wormes in Olives especially, called Drupæ; which beginning but then to ripen, are most readie to fall from the tree. And verily those trees which grow in waterie places or neare rivers, are most subject to have worme-eaten fruit, which although it fall not so soone, yet it is as loathsome every way.

Over and besides, there is a certaine kind of flie resembling the Gnat, which annoieth some
C trees and their fruits, and namely, Mast and Figs: and it seemeth that this flie is engendred of a certaine sweet humour that lyeth under their barkes. Thus much as touching all diseases to speake of, that trouble trees.

As for the impressions of the Aire at certaine seasons, as also of other accidents occasioned by the climat, they are not properly to bee called Maladies, becaufe they kill trees sodainly: as namely, when a tree is blasted outright, or all at once doth wither and drie away: like as when some puffe of an untoward wind peculiar unto any region, doth sucke them: such as in Apulia they call * Atabulus, and in Eubœa named Olympias: For if this wind chaunce to blow in mid-
D winter, it biteth, burneth, and drieth up trees with such cold blasts, as afterwards no heat of the Sunne is able to recover againe. In this sort likewise, all trees growing in vallies or standing along rivers sides, be endaungered: and above all others, Vines, Olives, and Figge trees. This death that they thus take, is soone after discovered and seene in the budding time when trees begin to put foorth, howsoever it be later ere the Olive shew it. Howbeit, a good signe it is in them all of their recoverie, when they loose their leaves: for you shall see the leaves tarie on in many of them, and when you thinke they are past the worst, sodainly die. Otherwhiles also you shall have the leaves to fade and seeme drie, yet afterwards the same trees to revive againe, and become greene. Furthermore, in the Northerly regions, as in Pontus and Phrygia, some trees there are that be ordinarily frozen to death; namely, when the frost and yce continueth after mid-winter fortie daies. And not onely there, but also in other countries, if immediatly after that trees have put foorth their fruit, there follow a hard frost, they will die upon it, although
E the frost last not many daies.

In a second ranke of causes that may kill trees, are to be raunged the injuries and wrongs that come by mans hand. Pitch, oyle, and grease, are very enemies and hurtfull to them all, but especially to young trees. Againe, if trees be barked round about, they will die all, unlesse it be the Corke tree; for it will thrive and prosper the better, if it bee in that wise discharged of the outward barke; for growing as it doth over thicke, it claspeth and clingeth the tree so hard, that it choketh and strangleth it againe. Neither doth the tree Adrachne find any hurt or offence by disbarking, unlesse the very wood be cut also togither with it. As for Cherrie trees, Lindens, and Vines, it is ordinarie with them to cast their barke in some sort, and take no harme thereby; but it is not the vitall and lively inner barke in deed which is next unto the bodie, but that onely
F which by comming of another underneath fresh and young, is driven forth and thrust out.

Some trees there be, which naturally have their barke full of chaps and rifts, as the Planes for example. As for the Line or Linden tree, if it chaunce to leese the barke, it will come in manner whole and entire againe. In such therefore the manner is, by way of cure to close up againe with clay and dung, the naked and bare place, and so to bring it to a cicatrize. And, I as-

* *quasi ἀήλιον, i. calamitatem aut pestem inferens.*

sure you, this practise sometimes speeds well, and doth the deed; provided alwaies, that the naked place were not surprised before the cure, with extremitie either of coid or heat. Certaine it is, that by this meanes both kinds of the Oke, as well the Robur as the Quercus, live the longer, and die nothing so soone as otherwise they would. And herein the time of the yeere ought to be considered, when a tree is thus pilled and disbarked: for in case that a man pill the barke of the Firre or Pine tree, during those moneths wherein the sunne passeth through the signes of Taurus or Gemini, which is the very season of their budding, there is no way but one with them, for presently they die: but if this wrong should befall them in winter, they would abide it the better and longer live, than beeing so misused either in Aprill or May. The same is the case of the mast Holme, the wild Robur also, and the common Oke. Howbeit, take this note by the way, that if the void place where the tree hath ben barked round about, be but narrow, so as the brims of the barke remaining be not farre asunder, the trees aforesaid will take no harme at all thereby. Mary in the tenderer sort, and such as a man may say are but of a weake complexion, and growing besides in a leane and hungrie ground, if the barke be taken away but of one side and no more, it is enough to kill them. G H

The like may be said of the topping or beheading the Cypresse, the Pitch tree, and the Cedar: for let these have their heads either cut off with an axe, or burnt by fire, they will die, there is no remedie. As much also is to bee said, when beasts doe brouse and eat them. As for the Olive tree, if a Goat chaunce but to licke thereof, it will thereupon proove barraine and beare no more Olives; so saith *Varro*, as wee have noted heretofore. But as some trees upon the like injurie done unto them, will die, so others againe will be but the worse for it; and such are the Almond trees: for where before they did beare sweet Almonds, they will ever after bring bitter. Moreover, you shall have some trees, that willl thrive and doe the better after this hard dealing, and namely, a kind of Peare tree called Phocis, in the Iland Chios: for you have heard by me alreadie, which trees they be that lopping and shredding is good for. I

Most trees, and in manner all (except the Vine, Apple tree, Fig tree, and Pomegranat tree) will die, if their stocke or bodie be cloven: and some be so tender, that upon every little wound or race that is given them, yee shall see them to die: howbeit, the Figge tree, and generally all such trees as breed Rosin, defie all such wrongs and injuries, and will abide any wound or bruse whatsoever.

That trees should die when their roots are cut away, it is no marveile: and yet many there be of them, that will live and prosper well neverthelesse, in case they be not all cut off, nor the greatest master roots, ne yet any of the heart or vitall roots among the rest. K

Moreover, it is often seene, that trees kill one another when they grow too thicke; and that, either by overshaddowing, or else by robbing one another of their food and nourishment. The Ivie also, that with clipping and clasping bindeth trees too hard, hasteneth their death. Misselto likewise doth them no good; no more than the Cytisus, or the herb Auro, which the Greekes name Alimus, growing about them. The nature of some plants is, not to kill and destroy trees out of hand, but to hurt and offend them onely, either with their smell, or els with the mixture and intermingling of their owne juice with their sap. Thus the Radish and the Lawrell doe harme to the Vine if they grow neare unto it: for surely the Vine is thought to have the sense of smelling, and wonderfully to sent any odours: and therefore it is observed in her by experience, That if shee be neare unto Radish or Lawrell, shee will turne away and withdraw her selfe backeward from them, as if shee could not abide their strong breath, but vtterly abhorred it as her very enemie. And upon the observation of this secret in Nature, *Androcydes* the Physician devised a medicine against drunkennesse, and prescribed his patients to eat Radish if they would not be overcome with wine. Neither can the Vine away with Coleworts or the Cabbage, nay it hateth generally all Woorts or pot-hearbs: it abhorreth also the Hazell and Filberd tree; in such sort, as a man shall sensibly perceive it to looke heavily and mislike, if those plants aforesaid grow not farther off from it. And now to conclude and knit up this discourse, would you kill a Vine out of hand? lay to the root thereof nitre or salt-petre, and alumne, drench it with hote sea-water: or doe but apply unto it Beane cods, or the shales or huskes of the pulse Ervile, and you shall soone see the operation and effect of a most ranke and deadly poison. I M

CHAP.

A

Chap. xxv.

Of many and sundrie prodigies or straunge tokens and accidents about trees. Also of an Olive plot, which in times past was transported all and whole from one side of an high port-way to another.

In this treatise of the faults and imperfections incident to trees, me thinks I should doe well to say somewhat of the supernaturall occurrences in them observed: for we have knowne some of them to grow up and prosper without any leaves at all. And as there have been vines and
B Pomegranats seene to beare fruit, springing immediatly from the trunke, and not from braunch or bough; so there have been vines charged with grapes, and not clad with leaves: and Olives likewise had their berries hanging upon them whole and sound, notwithstanding all their leaves were shed and gone.

Moreover, straunge wonders and miracles have happened about trees, by meere chance and fortune: for there was an Olive once, which beeing burnt to the very stumpe, revived and came againe: and in Bœotia, certaine Fig trees, notwithstanding they were eaten and gnawne most piteously with Locusts, yet budded anew and put forth a fresh spring. Also it hath been marked, that trees have chaunged their colour, from blacke to white. And yet this is not alwaies a monstrous thing beyond naturall reason, and specially in such as come of seed, as we may observe in
C the Aspe, which eftsoons turneth to be a Poplar. Some are of opinion, that the Service tree, if it be transplanted and come into a hoter ground than is agreeable to the nature therof, will leave bearing and be barrain. But it is taken for no lesse than a monster out of kind, that sweet Apples and such like fruits should proove sowre; or sowre fruit turne to be sweet: as also that a wild Fig tree should become tame, or contrariwise. And it is counted an unluckie signe, if any tree change from the better to the worse; to wit, if a gentle garden Olive degenerate into the wild and savage: if a vine that was wont to beare white grapes, have now black upon it: and so likewise if a Fig tree which used to have white Figs, chaunce afterwards to beare blacke. And here by the way, I can not forget the straunge accident that befell in Laodicea, where (upon the arrivall of K. *Xerxes*)
D a Plane tree was turned into an Olive. But if any man be desirous to know more of these & such like miracles, forasmuch as I love not to run on still and make no end, I referre him over to *Aristander* a Greeke writer, who hath compiled a whole volume and stuffed it full of such like wonders: let him have recourse also to *C. Epidius* a countreyman of ours, whose commentaries are full of such stuffe; where he shall find also, that trees sometimes spake.

A little before the civill warre brake out betweene *Iulius Cæsar* and *Pompey* the Great, there was reported an ominous and fearefull sight presaging no good, from out of the territorie of Cumes, namely, That a great tree there sunke downe into the earth so deepe, that a very little of the top-boughs was to be seene. Hereupon were the propheticall bookes of *Sibylla* perused, wherein it was found that this progedie portended some great carnage of men; and that the nearer that this slaughter & execution should be to Rome, the greater should the bloudshed be.
E A prodigious signe and wonder it is reputed also, when trees seeme to grow in places where they were not woont to be, and which are not agreeable to their natures; as namely, upon the chapters of pillars, the heads of statues, or upon altars: like as to see one tree of a divers and contrarie kind growing upon the top of another; as it befell about the cittie Cyzicum hard before the streight siege that was laid unto it [by *Mithridates*] both by sea and land, where a Fig tree was seene to grow upon a Lawrell. Likewise at Tralleis, about the time of the foresaid civill warre, a Date tree grew out of the base or foot of a columne that *Cæsar* Dictatour caused there to be erected. Semblably at Rome also, twise during the warre betweene the Romans and king *Perseus*, there was a Date tree knowne to grow * upon the lanterne or top of the Capitoll tem-
F ple; foreshewing those victories and triumphs which afterwards ensued, to the great honour of the people of Rome. And when this was by stormes and tempests overthrowne and laid along, there sprung up of it selfe in the very same place, a Figtree, at what time as *M. Messala* and *Caius Cassius* the two Censors, held their Quinquennall solemne sacrifices for the assoiling and purging of the citie of Rome: from which time *Piso* (a renowmed Historiographer and writer of good credit) hath noted, that the Romanes were given over to voluptuousnesse and sensualitie,

* or as some read, the head of *Iupiter* within the Capitoll.

and that ever since all chastitie and honest life hath been exiled. But above all the prodigies that were ever seene or heard, there is one that passeth, and the same happened in our age, about the very time that *Nero* the Emperour came to his unhappie end and fall: For in the Marrucine territorie there was an Olive garden belonging to *Vectius Marcellus*, a right worshipfull knight of Rome, which of it selfe remooved all and whole as it stood over the broad high way, to a place where lay tillage or erable ground: and the corne lands by way of exchange, crossed over the said causey againe, and were found in lieu of the Olive plot or hortyard aforesaid.

Chap. xxvi.

The remedies for the maladies and diseases of Trees.

NOw that I have declared the diseases of trees, meet it is that I should set downe the cure and remedies thereto. Where, this one thing would be first noted, that of Remedies, some be common to all trees, others appropriate to certaine. Common be these following, To bare and cleanse the roots, to hill and banke them again; that is to say, to give aire unto the roots, and let the wind into them: and contrariwise to cover them, & keep both wind and weather from them: to water them, or to derive and divert water from them: to refresh their roots with the fat liquor of dung: to discharge them of their burden, by pruning their superfluous branches. *Item* To give their humors issue, and as it were by way of Phlebotomie to let them bloud: and to skice and scrape their barke round about, in manner of scarification. To take downe their strength and keepe them under, that they be not too lustie and prowd. Also, if the cold hath caught their buds or burgeons, and therby caused them to looke burnt, rough, and unpleasant; to slicke, pollish and smooth them againe with the pumish stone. These verily bee the divers remedies to cure trees: howbeit, used they must bee with great discretion: for that which is very good for one, is not so good for another: and some trees require this course and others that, to bee taken with them. As for example, the Cypresse tree cannot abide either to be dunged or watered, it hateth all digging and delving about it, it may not away with cutting and pruning, it is the worse for all good Physicke, nay, all remedies to others, are mischeefes to it; and in one word, goe about to medicine it, you kill it. All Vines, and Pomgranat trees especially, love a life river-sides, and desire to be watered: for thereby will they thrive and prosper. The Fig tree also it selfe is nourished and fed in waterie grounds: but the fruit that it beareth, is the poorer by that meanes. Almond trees if they be plied with digging, will either not bloume at all, or else shed their flowers before due time. Neither must any yong plants or trees, newly grafted, be digged about their roots, before they have gathered sufficient strength, and begin to beare fruit. Most trees are willing inough to be disburdened of their superfluous and over-ranke braunches, like as we men can spare our nailes to bee pared, and bush of haire to be cut when they be overgrowne. As for old trees, they would bee cut down hard to the ground, for commonly they rise againe of some shoot springing from the root: and yet not all of them. Regard therefore must be had, that none be so used but such (as wee have noted before,) as are able of nature to abide it. For trees to be watered at the roots in the heat of summer, it is good, but in winter it is as bad. In the fall of the leafe it may be holesome, it may also be hurtfull, and therefore the nature of the soile would be considered: for the grape-gatherer in Spaine, meeteth with a good Vintage, notwithstanding the Vines stand in a marish and fennie ground; howbeit, in most parts of the world besides, it is thought good husbandrie to draine away from their roots the very raine water that falleth from above, in Autumne. About the rising of the Dogge-star, trees desire most of all to be well watered: and yet they would not have too much thereof, even in that time; for in case their rootes bee over-drenched and drowned therewith, they will catch harme. Herein also the age of trees is to bee respected, which in this case prescribeth what is meet and sufficient: for young trees bee lesse thirstie than others. Also, custome is a great matter. For such as have beene used unto watering, must not chaunge their old woont, but they require most of all others to be used so still. Contrariwise, those trees that grow upon drie grounds naturally, desire no more moisture than that which is needfull. In the territorie about Sulmo, in Italie, and namely, within the liberties of Fabianum, the Vines that beare the harder and sourer grapes, must of necessitie bee watered: and no marvaile, for the verie lands and corne-fields use to have water let in unto them. And here a wonderfull thing is to be observed, This water cherisheth the corne, but killeth all the hurtfull grasse among: and

A the river overflowing the lands, is as good as a weeding. In the ſame countrey the manner is in midwinter to open a ſluce or draw up their floud-gates, for to overflow their Vine roots with the river: and ſo much the rather, if either it be an hard froſt, or ſnow lie upon the ground: And why ſo? becauſe the pinching cold ſhould not burne them: and this they call there by the name of Tepidare, [*i.* to give them a kindly warmth as in a ſtouve:] ſee the memorable nature of this onely river, to be warme in winter; and yet the ſame in ſummer is ſo cold, that hardly a man can endure his hand in it.

Chap. xxvii.

Of caprification or ſcarifying trees: alſo the manner of dunging them.

B TOuching the remedies for blaſting as well by heat as cold, I will treat in the book next following. Meane while I cannot omit one manner of cure by way of Scarification. For when the barke is poore and leane, by reaſon of ſome diſeaſe or miſliking, ſo as it clenseth together, preſſing and binding the quick wood overmuch, whereby the tree is as it were hide-bound, they uſe to ſlit the ſame along with a very ſharpe cutting hooke, guiding and gaging the edge thereof with both hands, that it goe not over-deepe: and ſo by theſe inciſions they doe open it, and as it were loſen and enlarge the skin. Now, when this feat is wrought, the onely ſigne that it is well done and good for the tree, is this, if the inciſions in tract of time appeare wide, and the void place incarnate againe and fill up with a kind of callous ſubſtance, compounded of the ſap and wood together growing betweene. Whereby it appeareth, that in many caſes the cure of
C mens maladies and the diſeaſes of trees is very like: for that even their bones alſo uſe to be trepanized and bored through as well as ours. Alſo for to make ſweet Almonds of bitter, firſt the tree muſt bee digged round about, and then boared through with an augoer toward the root or butt end, whereby the wateriſh humor that runneth downward, may iſſue forth and paſſe away. Moreover, if a man would diſcharge Elmes of their ſuperfluous moiſture, they muſt be pierced with a wimble, a little above the ground, as far as to the very heart or pith; if either they bee old, or be perceived to receive overmuch nutriment. In like manner the ſame exceſſive humour is let out of Figge trees by the meanes of certaine light ſlits or gaſhes made in the barke, aſlant or byas, in caſe it ſeeme to ſwell and bee over-ſtreight: and by this deviſe they prevent the falling of their fruit.

D Generally, what trees ſoever bearing Apples or ſuch like ſoft fruit without, if they chaunce at any time to prove barren, that is to ſay, to put foorth leafe onely without any fruit; the uſe is, firſt to make a clift in the root; then, to put a ſtone therein, that the edges meet not and rejoin again; and ſo they become fruitfull. The ſame is practiſed in Almond trees alſo, but in ſteed of the ſtone there muſt a wedge of Okewood be driven in. As for Pyrries and Medlar trees, thoſe wedges muſt be made of Pine Torch-wood. Moreover, if either Vines or Figge trees, be over ranke of wood, it is very good to cut and skice their roots round about, and when they bee thus ſerved, to cover with aſhes the ſaid inciſions: but then they muſt be cloſe covered with aſhes and earth aloft. If yee would have trees beare Figges at the latter end of the yeare, plucke off the firſt greene Figges ſo ſoone as they bee ſomewhat bigger than Beanes: for under them there will other come up in
E the place, and be later ere they waxe ripe. The ſame Fig-trees when they begin to ſpring leafe and looke greene, if the top-twigs of every bough be cut off, become the ſtronger and more fruitfull by it. For as touching the ripening of Figges by Caprification, true it is, that there bee certaine flies like gnats engender in greene Figs, which are the occaſion thereof: for when they are flown out, there are no graines or ſeeds found within: whereby it is evident, that they bee turned into thoſe flies. And when they doe flie forth, ſo haſtie they are to be gone, that many of them as they breake out, leave either a foot or a wing behind them. Beſides, another kind there is of gnats, which they call Centrinæ, for ſlouth and ſhrewdneſſe like in all the world to Drone-bees, ſo miſcheevous they be to the good flies or gnats indeed, that cauſe the Figs to ripen: for, them they kill, and die themſelves when they have done. Moreover, there bee certaine wormes like mothes,
F that ordinarily doe much hurt to the graines or ſeeds within Figs, and eat them quite: The only remedie againſt this vermine, is to take a twig or impe of the Italian Lentiske tree, and to ſet or couch it with the wrong or top-end downeward, in the very ſame trench where the Fig tree was planted. For to have Fig trees beare moſt plentifully, take ruddle or red-earth tempered well with the lees or grounds of oile, after that the ſame is mixed with dung, poure it to the roots of the

trees when they begin to put forth leaves. Among wild Fig trees, the best are the black and those that grow in stonie grounds: for their Figges are fullest of cornes or graines within. And as for caprification, it would be practised after raine. And take this for a generall rule, That yee beware in any hand in curing of trees, least yee use a mischeefe for a remedie, a thing that commonly happeneth by over many medicines, or the same not applied in due season. For as it is very good for trees, to lop and cut off their boughs where they grow too thicke: so to be hacking and mangling of them every yeare, hurteth them as much. As for the Vine, it requireth pruning once a yeare: but the Myrtle trees, Pomgranate, and Olive trees, every two yeares; because they will quickly spring againe and shoot forth branches thicke. Other trees would not bee lopped so often. Neither is it good to cut or prune any whatsoever it be, at the fall of the leafe. Nay, they are not so much as to bee scraped, but in the pruning time, that is, in the Spring. All wounding of trees goeth to the very heart, and hurt the quicke, unlesse it be of those parts that are superfluous.

As great consideration there would be had in the manner of mucking them. No doubt, they love dung well: but carefull heed would be taken first, that none bee laid to their roots in the hotest season of the yeare. *Item*, That it be not greene, but throughly rotten: lastly, that it bee not over ranke nor stronger than is needfull. Swines dung burnes the roots of Vines, unlesse it bee five yeares old, or the Vines stand in some place where water is at commaundement, for to coole the excessive heat thereof. Also the filth of Tanners ooze and Curriers scrapings doe the like, if they be not well delaied with water. Likewise it must not be laid too thicke. The ordinarie proportion is thought to be for every tenne foot square, three Modij of dung. But herein no certainetie can be set downe: for the nature of the soile must rule all. With Swines and Pigeons dung, they use to soulder the cuts and wounds that are given to trees. In case the Pomgranates grow to bee tart and soure, the manner is to dig about the root and lay it bare, and then to put Hogs dung thereto: for that yeare the Pomgranates will be full of a wine juice; and the next yeare following prove sweet. Some good husbandmen there be, that thinke it meet and requisite foure times a yeare to water their roots with mans urine and shere water together, and upon every one they bestow a whole Amphore. Or else to bedeaw and sprinckle the top-braunches of the Pomgranat trees with wine, wherein Laser hath beene steeped. When the Pomgranate doth cleave and open upon the tree, it is good to wreath the steale thereof. If Figges doe the like, there would bee oile lees cast upon them. Other trees when they are amisse or doe mislike, ought to be drenched with wine lees: and Lupines if they bee set about their roots, will helpe them. The water also or decoction wherein Lupines were sodden, poured about the roots of Apple trees or such like, dooth them much good. If it happen to thunder about the feast Vulcanalia, Figges will fall from the tree. The remedie thereof is to strew the plots before with Barley straw. Would you have hastie Cherries? Lay lime to the roots of the tree, it will cause them to ripen their fruit speedily. Of all fruits these hastie Cheries would bee plucked and gathered as they ripen, to the end that those which be left behind, may thrive and grow big and faire.

Chap. xxviii.

Many and sundrie medicines serving for trees: to wit, remedies against venomous vermine and Pismires, likewise against all hurtfull beasts.

SOme trees there bee which are the better for wrong and injurie done unto them: yea, and if they be pinched or bitten, they shoot up the rather, as Date trees and the Lentisks; for even the very salt water nourisheth them. And true it is, that ashes hath the like nature and vertue that salt, howbeit, more mild and gentle. Hereupon it commeth also, that Fig trees use to bee strewed therwith, yea, and to be wet with the juice of Rue, to the end, that neither their fruit should prove worme-eaten, nor their roots putrifie and rot. Moreover, if Vines bee too full of moisture, and apt to bleed overmuch, it is an ordinarie thing to poure salt water to their roots. Also, in case their grapes be apt to fall, folke use to take ashes and besprinckle them with vinegre, and so to besmeare the roots therewith: or else with red Orpiment, in case the grapes be given to putrifaction. Say that Vines be barren and will not beare grapes, their roots ought to bee well drenched and dawbed with sharpe vinegre and ashes incorporate together. But what if a Vine bring not her fruit to full maturitie, before it begin to waxe drie and to wither? the superfluous wood ought to bee cut away about the root, and the cuts together with the small strings or beard of the root to

be

A be wet and soked in sharpe vinegre and stale chamber-lee, and then they should bee well covered and stopped with a kind of morter made therewith, and often digged about. As for Olives, if they make shew of small encrease, their roots must be bared and laid open to the cold in winter; for by this manner of chastisement they will amend and doe far better.

In all these remedies, proceed wee must according to the course of the yeare: for sometime the season requireth, that the meanes should be sooner used, and otherwhiles later. Some plants there be that fire is good for, and namely, canes and reeds: for if they be burnt, they will come up againe the thicker and more smooth. As for *Cato*, hee hath certaine compound medicines for trees, distinct by sundrie measures by him prescribed: for hee hath ordained to the roots of the greater trees an *Amphore, but of the lesse an *Vrna onely, of Oile dregs, with an equall quan-

B titie of water: all which being tempered together, he would have to be poured by little and little to the roots, but they ought before to be digged about and laid bare. And for the Olive, hee addeth moreover, that the roots should have a bed of litter or straw made before, and then used accordingly. In like manner also would the Fig tree be served: but especially at the roots of it there should bee raised a banke of old earth: for by that meanes it will come to passe, that the greene Figs will not fall, they will beare more plenteously, and the fruit bee more smooth and pleasant. To prevent in like manner, that the worme *Convolvulus bred not in a Vine, hee appointed two gallons of oile dregs or lees, to be boiled first to the thicke consistence of honie, and then afterwards to take a third part of the slime Bitumen, and a fourth part of brimstone, and seeth all to-

C gether againe in the open aire; for within dores there would be some danger of setting the house a fire. With this mixture, if a Vine bee well annointed about the joints, and under their hollow armepits, he assureth us, that there will no such worme breed therein. Some content themselves to perfume Vines onely with the smoke of this composition, so as it bee done on the wind-side, that it may carie the fume directly to them; and this should bee continued for three daies together. Many are of opinion, that wine being mingled with a like quantitie of water (because alone of it selfe it is hurtfull) is as good for this purpose as the oile dregs aboveseid, which *Cato* hath prescribed. Another kind of vermine or worme there is, that gnaweth the tender buds or burgeons of the Vine, and the same is called Volvox: To preserve Vines from this harmefull creature, men are wont to take their Vinehookes when they be newly ground & sharpened, then to scoure them with a Beavers skin, and with them to prune the Vines: or else after they bee pruned, to an-

D noint them with Beares bloud. Moreover, Ants or Pismires make foule worke otherwhile among trees. If you would drive them away, dawbe the stock or butt end with red Sinopre and Tar tempered together. Or doe but hang up any fish neare by, and all the Pismires will leave their former haunt, and gather about it. Others make no more adoe, but stampe Lupines with oile, and therewith annoint the roots. Many there are, who kill both them and Moldwarpes with oile dregs. Also, against Palmer-wormes or Caterpillers, and to keepe Apples from rotting, they give order for to annoint the top twigs and branch ends of trees with the gall of a greene Lizard. But more particularly against the said Caterpillars, they would have a woman whiles her monthly sicknes is upon her, to goe round about every tree by it selfe, barefooted and barelegged, unbraced and unlaced, and her haire hanging about her eares. Moreover, to preserve trees from wild and noi-

E some beasts, that none of them come neare to bruse and marre their greene spring, they doe appoint to bespreint their leaves with greene Cow or Oxe shearne, and water together, betweene some showers, that the raine may wash away the mallice and hurtfull qualitie of the medicine. A wonder to see how inventive men are to devise remedies for every mischeefe: for many you shall have, who be verily perswaded, that there be certain charmes and inchantments to drive away the haile. But for mine owne part, I thinke it meere mockerie to set downe the very words, although *Cato* hath done it before mee. Who also speaketh of another spell for dislocations or members out of joint (an accident happening to trees) which he would have to bee joined close within the clift of canes. The same writer hath permitted men to cut downe sacred groves, trees also dedicated for religion and sequestred from prophane use (after a solemne sacrifice to the gods first

F performed:) the reason and manner whereof he hath put downe in a certaine Treatise, which he compiled of purpose as touching that argument.

*Amphora, or, *Quadranta*, was a measure Roman of liquor, conthining 16 *Congij*, which is much about 16 wine gallons.

*Vrna, is halfe *Amphora*, to wit, 8 gallons, or thereabout.

* Vine fretter, or the Divels gold-ring.

THE

THE XVIII. BOOKE OF THE HISTORIE OF NATVRE,

WRITTEN BY C. PLINIVS SECVNDVS.

Chap. I.

Of the exceeding love and affection of our auncestors in old time to Agriculture and Husbandrie. Also, of their singular paines and diligence about gardens.

NOw followeth the treatise of Corne, of Gardens, and Flowers, and generally of all things else, that by the goodnesse of Nature the Earth bringeth foorth bountifully, besides Trees and Shrubs. The speculation whereof verily is infinite, if a man doe but consider the number and varietie of Hearbs and Flowers, togither with their odors and colours; the diversitie also of their juices, their severall vertues and properties, whether it be to cure men of their maladies, or to give them pleasure and contentment to their senses. But before that I enter into this discourse, very willing I am to take in hand the cause of the Earth (the common mother of us all) and to assist her against all slaunderous imputations, notwithstanding I have in the beginning of this my worke pleaded once alreadie in her defence. For when wee looke into the matter within her contained, we are set on fire inwardly to find fault with her for breeding and bearing noisome things, charging upon her our owne faults, and imputing unto her that, for which wee of right ought to be blamed. Set case shee hath brought forth poison and venime, Who hath searched them out but man? As for the foules of the aire and wild beasts, it is sufficient that they touch them not, nay they know how to beware and avoid them. For say that the Elephants doe file their teeth sharpe against hard trees, say that the Rhinocerotes whet their hornes against the rockes, and the wild Bores sharpen their edge tuskes against both stocke and stone; say that all creatures know well enough how to prepare and frobish their weapons to do mischiefe, Which of them all yet infect them with poison, but man alone? We have the cast to envenime and poison arrowes; we can tell how to put something to our darts of yron and steele, more hurtfull and mischievous than they be. It is ordinarie with us to poison rivers also; yea and the very Elements whereof the world doth stand, are by us infected: for even the Aire it selfe, wherein and whereby all things should live, we corrupt to their mischiefe and destruction. Neither can we truly say or thinke, that other creatures besides us are ignorant of these poisons; for wee have alreadie shewed, that they are not to seeke either what defensatives to provide against they should fight with serpents, or what remedies to find for their cure after they have fought and are hurt. Moreover, setting man aside, there is no creature furnished or armed with any other venime, but their owne. We cannot chuse therefore but confesse our great fault and deadly malice, in that we rest not contented with naturall poisons, but betake our selves to many mixtures and compositions artificiall, made even with our owne hands. But what say you to this? Are not some men themselves meere poisons by nature? for these slaunderers and backbiters in the world, what doe they else but launce poison out of their blacke tongues, like hideous serpents? what doe these envious persons, but with their malicious and poisonfull breath sindge and burne all before them that they can reach or meet with, finding fault with every thing whatsoever? Are they not well and fitly compared to these cursed foules flying in the darke, which albeit they sequester themselves from

A from birds of the day, yet they bewray their ſpight and envie even to the night and the quiet repoſe thereof, by their heavie grones (the onely voice that they uttet) diſquieting and troubling thoſe that be at reſt: and finally, all one they be with thoſe unluckie creatures, which if they happen either to meet or croſſe the way upon a man, preſage alwaies ſome ill toward, oppoſing themſelves (as it were) to all goodneſſe, and hindering whatſoever is profitable for this life. Neither doe theſe monſtrous and abominable ſprites know any other reward of this their deadly breath, their curſed and deteſtable malice, but to hate and abhor all things. Howbeit, herein may we acknowledge & ſee the wonderfull majeſtie of dame Nature: for like as ſhe hath ſhewed her ſelfe more fruitfull and liberall in bringing forth profitable and holeſome plants, in greater plentie than hurtfull and noiſome; ſo ſurely hath ſhe furniſhed the world better with good men
B and vertuous for the weale publicke. In which regard and conſideration, we alſo taking no ſmall joy and contentment (leaving theſe troubleſome ſpirits to themſelves for to broile and frie in their owne greace) will goe on forward and proceed to declare the reſt of Natures workes; and with the better reſolution, for that wee ſeeke more pleaſure and contentment in the paines and travaile that we take, than expect any fame or bruit of men afterwards. For why? we are in hand to ſpeake of the countrey and countrey commodities, ſuch as in old time like as they were moſt neceſſarie for this life, ſo they were accounted and honoured moſt highly.

Chap. II.

Of the firſt guirland or chaplet made of hearbs and flowers at Rome.

C THe firſt order that king *Romulus* inſtituted in Rome citie newly built, was the guild or fraternitie of certaine Prieſts or Wardens over corne fields, which were in number twelve. And for to doe the greater honour to this companie, he cauſed himſelfe to be called the twelfth brother among them: and *Acca Laurentia*, the nource or foſter-mother of this Prince, beſtowed upon him a guirland of corne eares, twiſted and tied togither with a white ribband, as the moſt ſacred badge and enſigne of this new prieſthood, which he and his brethren ſhould weare with great reverence and devotion: and this was the very firſt chaplet knowne at Rome. Now the honour of this ornament was perpetuall, and continued for terme of life; ſo as a man once inveſted therein, could not be degraded and deprived thereof, though hee were baniſhed or taken
D priſoner; it accompanied him ever to his dying day. Then, and in thoſe daies, every man within the whole bodie of the people of Rome, contented himſelfe with two acres of land, and K. *Romulus* aſſigned to none of his ſubjects a greater proportion: whereas now yee ſhall have thoſe that erewhile were but ſlaves and ſervants under the Emperour *Nero* (deſpiſing as not ſufficient, greene encloſures and gardens of that compaſſe) muſt have fiſhpooles alſo bigger than ſo: and well it were if they would ſtay there and goe no further, for ſhortly we ſhall ſee ſome one or other of them, never reſt untill hee have kitchins alſo more than two acres wide. And thus much for king *Romulus*.

King *Numa* his ſucceſſor, ordained to worſhip the gods with an oblation of corne, yea and to offer prayers and ſupplications unto them by no other meanes, than cakes made of ſalt and
E meale: yea and as *Hemina* mine author ſaith, for to induce the people of Rome the better unto it, he allowed them to parch their corne in their ſacrifices; for that corne thus parched, was ſuppoſed to be a more holeſome food: by which meanes, this one thing enſued in the end, that no corne was counted pure and good, nor fit to bee uſed in divine ſervice, but that which was thus baked or parched. He alſo inſtituted the feaſt Fornacalia, to wit, certaine holydaies for the parching and baking of corne: as alſo another as religiouſly obſerved, called Terminalia, namely, for the bounds and limits of lands: for theſe and ſuch like gods, as then, they worſhipped moſt: as alſo the goddeſſe *Seia*, ſo called *à ſerendo*, [*i.* of ſowing corne and ſetting plants:] and *Segeſta*, which name they gave her *à ſegetibus*, [*i.* of corne fields:] whoſe images wee at this day doe ſee in the grand Cirque or Shew-place at Rome. A * third goddeſſe there is among them, whome
F to name and invocate within-houſe, they might not with ſafe conſcience. Laſtly, ſo religious and ceremonious they were in old time, that they would not ſo much as taſt of new corn or wine, before the Prieſts had taken a ſey of the firſt fruits.

* *Tertiam*, to wit, *Tutelina*, ſo preſerving of trees planted, & corne ſowne: or as ſome read (*Terminum*) meaning *Terminus*.

Chap.

Chap. iii.

Of Iugerum, and Actus. Of the ancient lawes ordained for cattell in old time. How often and at what times corn and victuals were exceeding cheape at Rome. What noble and famous persons addicted themselves wholly to Husbandrie and Tillage.

AN Acre or Arpen of ground, called in Latine Iugerum, was as much as might be eared up or ploughed in one day with a yoke of Oxen. And Actus in Latine, is a land, or so much just as two Oxen are driven and occupied in, whiles they plough in one tract without any rest. This contained by the old time, a hundred and twentie foot in length: and being doubled in length, made the Acre or Iugerum abovesaid.

In auncient time of the old Romanes, the greatest present that could be given to captaines and souldiors who had borne themselves valiantly in the service of their countrey, was as much ground as they could have eared or broken up in one day. And it was thought a great reward to receive at the hands of the people of Rome halfe a pint (or a pint at the utmost) of corne. Moreover, in so great request was Corne and Husbandrie, that the first and cheefe houses in Rome took their surnames from thence: and namely, the *Pilumni*, who devised first the pestill to bray corne withall in their mils and back-houses: also, the familie of the *Pisones*, who tooke their name, *à pisendo*, [*i.* of stamping or pounding corne in a morter.] The *Fabij* in like manner, the *Lentuli*, and the *Ciceroes*, each one according to the severall pulse that they skilled best to set or sow. Moreover, to the house of the *Iunij*, they gave the surname of *Bubulcus*, by occasion of one of their ancestors, who knew passing well how to use and order Oxen. Over and besides all this, that you may know what regard was had of Corn, among other sacred and holy ceremonies, there was nothing reputed more religious than the bond of Confarration, in knitting up of mariages, and assurance making of the cheefe priests: yea, the manner of the new wedded brides was to carie openly before them a wheaten cake. In times past, the Magistrates called Censors, judged it a trespasse worthie of a great rebuke, to bee an ill husband, that is to say, to bee careless and negligent in tilling the ground. And as *Cato* reporteth, if men called one by the name of a good Husbandman, they were thought to have praised & commended him in the highest degree. Hereupon also it came, that rich and substantiall men were tearmed in Latine, Locupletes, as one would say, Loci-pleni, [*i.* well landed.] And as for the very word, Pecunia in Latine, which signifieth money, it tooke the name of Pecus, that is to say, cattell. And even at this day (as it appeareth in the Registers of the Censors, and the accounts of the citie chamber) all their rents, revenues, and customes growing unto the people of Rome, are called Pascua; for that a long time the whole domaine of Rome, stood upon pasturage and nothing else. The penalties and fines also, which offendants were put to pay, were raised of nothing else but of Kine, Oxen, and Sheepe: where, by the way, I cannot conceale from you the favourable regard that the auncient lawes and ordinances of Rome had; whereby it was expressely forbidden, That no Iudge who had power to enjoine or impose any paine and amercement, should name the fine of an Oxe, unless hee had passed that of a Sheepe first. The solemne games and plaies also in the honour of Kine and Oxen, they who frequented them, called Bubetij. Moreover, king *Servius* at the first when he made brazen coine, stamped the peeces with the portraiture of Sheepe, Kine, and Oxen. By the lawes of the twelve Tables, all persons whatsoever above foureteene yeares of age, were forbidden under paine of death, either by stealth, to feed their cattaile in the night time upon any corne-field of another mans, plowed and sowen; or to cut the same downe by syth or sickle at such a time, and in that manner. By the same lawes also ordained it was, That whosoever was attaint or convicted thereupon, should be hanged by the head and strangled for satisfaction of the goddesse *Ceres*: and in one word, to be more greevously punished than in case of manslaughter. But if the offender were under that age beforesaid, the same law provided, that he should be whipped at the discretion of the Pretor or lord cheefe Iustice for the time being: or, if this punishment were remitted by the partie who sustained the domage, then he should satisfie unto him for the trespasse as a slave, and pay double for the losse, according as honest and indifferent men valued it. Furthermore, in auncient time, the distinction of States and degrees in the cittie of Rome (both for wealth and worship) was according to their lands, and not otherwise. Insomuch, as those cittizens were reputed for cheefe and principall, who were possessed of land and living in the countrey: and these made the State, called the Rustick Tribes, in Rome: wheras contrariwise the other estate, reputed

the

A the meanet in degree, was named the Vrbane Tribes; conſiſting of Artiſanes & ſuch like as were not landed perſons: into which, if a man were transferred from any of the reſt, it was thought a great ſhame and diſgrace, as if hee were reproched for idleneſſe and negligence in husbandrie. And hereupon theſe foure Tribes alone tooke name of thoſe foure principall parts or quarters of the citie wherein they were ſeated, to wit, Suburrana, Palatina, Collina, and Exquilina. Over and beſides, upon faires & market daies, the Ruſticke Tribes uſually viſited the citie: upon which daies therefore no publicke aſſemblies of the people were holden, to call the Commons away from their market affaires. Alſo the manner in thoſe daies was to take their ſleepe and repoſe in good ſtraw and litter. Yea, and when ſpeech was of glorie and renowne, men would call it by no other tearme but Adorea, of Ador, a kind of fine red wheat. Where, by the way, I have in great
B admiration the antique words of thoſe times, and it doth me good to thinke how ſignificant they were. For thus we read in the ſacred Pontificall Commentaries of the high prieſts, *For the Augurie or ſolemne ſacrifice called *Canarium, let there be certain daies appointed, to wit, before that the corne ſhew eare out of the hoſe, yea, and before that it come into it.* But to returne againe to the praiſe of Husbandrie. When the world was thus addicted and given to Agriculture, Italie was not only well provided and ſufficiently furniſhed of corne, without any helpe from out-provinces; but alſo all kind of graine and victuals were in thoſe daies ſo exceeding cheape, as it is incredible. For *Manius Martius* a Plebeian Ædile of Rome, was the firſt man that ſerved the people wheat at one Aſſe the Modius: and after him *Minutius Augurinus*, the eleventh Tribune of the Commons, (even he who endited that mutinous and ſeditious citizen *Sp. Melius*) brought downe the price of
C wheat for three market daies to an Aſſe the Modius. The people therefore of Rome, in regard of this good deed of his, erected a ſtatue for him without the gate Trigemina; and that with ſuch affection and devotion, that every man contributed ſomewhat thereto by way of benevolence. *Trebius* alſo in the time of his Ædileſhip, cauſed wheat to bee ſold unto the people at the ſame rate, to wit, one Aſſe a Modius. For which cauſe, there were two ſtatues alſo in memoriall of him ſet up, both in the Capitoll and alſo in Palatium: and himſelfe when he was departed this life, had this honour done unto him by the people, at his exequies, as to bee caried on their ſhoulders to his funerall fire. It is reported moreover, That in the very ſame yeare wherein the great goddeſſe *Cybele* (called alſo the mother of the gods) was brought to Rome, there was a more plentifull harveſt that Summer, and corne was at a lower price than had been knowne in ten years
D before. Likewiſe, *M. Varro* hath left in writing, That when *L. Metellus* made ſhew of ſo many Elephants in his triumph at Rome, a Modius of good red wheat, was worth no more than one Aſſe. Alſo a gallon of wine coſt no more. And as for drie Figges, thirtie pound weight caried no higher price: and a man might have bought a pound of oile Olive, and twelve pound of fleſh at the very ſame reckoning. And yet all this plentie and cheapeneſſe proceeded not from the great domaines and large poſſeſſions of thoſe private perſons that encroched upon their neighbors, and hemmed them within narrow compaſſe. For by the law publiſhed by *Stolo Licinius*, provided it was, That no Romane citizen ſhould hold in private above five hundred Acres. The rigor of which law or ſtatute was extended and practiſed upon the Law-maker himſelfe, and by vertue thereof he was condemned: who, for to poſſeſſe above that proportion, and to defraud the mea-
E ning of the ſaid Act, purchaſed more lands in the name of his ſonne. Lo what might be the proportion and meaſure of poſſeſſions allowed even then, when as the State and Common-wealth of Rome was in the prime and began to flouriſh. And as for the Oration verily of *Manius Curius* after ſuch triumphs of his, & when he had ſubdued and brought under the obeiſance of the Roman Empire and laid to their dominion ſo many forrain nations; what it was, every man knoweth, wherin he delivered this ſpeech, That he was not to be counted a good man, but a dangerous citizen, who could not content himſelfe with a cloſe of ſeven acres of ground. And to ſay a truth, after that the kings were baniſhed out of Rome, and their regiment aboliſhed, this was the verie proportion of land aſſigned to a Romane Commoner. If this be ſo, What might be the cauſe of ſo great plentie & abundance aforeſaid in thoſe daies? Certes, this & nothing els, Great LL. and
F generals of the field (as it ſhould ſeeme) tilled themſelves their ground with their own hands: and the Earth again for her part, taking no ſmall pleaſure (as it were) to be eared and broken up with ploughs Laureat, and ploughmen Triumphant, ſtrained her ſelfe to yeeld encreaſe to the uttermoſt. Like it is alſo, that theſe brave men and worthie perſonages were as curious in ſowing a ground with corne, as in ordinance of a battell in array: as diligent (I ſay) in diſpoſing and ordering

* Made with a red dog to pacifie the Dog-ſtarre.

ting of their lands, as in pitching of a field: and commonly every thing that commeth under good hands, the more neat and cleane that the usage thereof is, and the greater paines that is taken about it, the better it thriveth and prospereth afterwards. What shall wee say more? was not [*C. Atilius*] *Serranus* (when the honourable dignitie of Consulship was presented unto him, with commission to conduct the Romane armie) found sowing his own field and planting trees, whereupon he tooke that surname *Serranus*? As for *Quintius Cincinnatus*, a pursevant or messenger of the Senat brought unto him the letters patents of his Dictatorship, at what time as he was in proper person ploughing a peece of ground of his owne, containing foure acres and no more, which are now called Prata Quintiana, [*i. Quintius* his medowes] lying within the Vaticane: and (as it is reported) not only bare-headed was hee and open breasted, but also all naked and full of dust. The foresaid officer or sergeant taking him in this manner, Doe on your cloths sir (quoth he) and cover your bodie, that I may deliver unto you the charge that I have from the Senate and people of Rome. Where, note by the way, that such Pursivants and Sergeants in those daies were named Viatores; for that eftsoons they were sent to fetch both Senatours and Generall captaines out of the fields where they were at worke: but now, see how the times bee chaunged! They that doe this businesse in the field, what are they but bondslaves fettered, condemned malefactours manacled, and in one word, noted persons and such as are branded and marked in their visage with an hot yron? Howbeit the Earth, whome wee call our Mother, and whome we would seeme to worship, is not so deafe and senslesse, but she knoweth well enough how she is by them deprived of that honour which was done in old time unto her: in so much as we may well weet, that against her will she yeeldeth fruit as she doth; howsoever wee would have it thought, by these glorious titles given unto her, that shee is nothing displeased therewith, namely, to be laboured and wrought by such vile and base hirelings. But wee forsooth doe marveile, that the labour of these contemptible bondslaves and abject villaines doth not render the like profit, as that travaile in former times of great Captains and LL. Generals. And in verie truth, even among other forreine nations, it was counted a princelike profession in deed, to bee able for to give rules and directions about Husbandrie: for so we may see, that both kings have studied this argument, as namely *Hiero*, *Philometor*, *Attalus*, and *Archelaus*: and also martiall captaines, to wit, *Xenophon*, and *Mago* the Carthaginian. As for *Mago* verily, our Senat did him that honour after Carthage was woon, that in sacking it and giving away among divers LL. of Affricke, the Libraries there found; they thought good to reserve onely 28 volumes of his, and penned by him as touching Agriculture, and to have them translated into the Latine tongue (notwithstanding that *M. Cato* had alreadie beforetime put out in writing and set forth certaine rules and precepts therof;) giving order for this Translation, to those that were well seen in the Punicke or Carthaginian language: in which businesse, *D. Syllanus* a Romane gentleman of a right worshipfull house, went beyond all others. As for great schollers and men of profound and deepe learning, a number there were besides that travailed in this matter, whome wee have named alreadie in the forefront; and eftsoons shall mention in the discourse of this volume. In which raunge we must nominate not unthankfully among the meanest writers, *M. Varro*, who being fourscore yeeres old and one, thought it not amisse to compile a speciall booke and treatise of Husbandrie.

Chap. iiii.

The manner of Husbandrie in auncient time.

LAte it was ere the Romans began to set their minds upon Vines and Vineyards: for at first they tilled only corne fields for very necessitie, even as much as might suffice to serve the citie. The order and manner whereof, I will set in hand to treat of; not after a vulgar and common sort, but according to my usuall manner hitherto, more soundly: as having sought out with all care and diligence, not only the ancient practise in times past, but the inventions also of late daies; and withall, searched into the causes and reasons of every thing, & found them out. My purpose is besides, to speake in this treatise of the fixed Starres, their rising and setting, their apparition and occultation, togither with their influences, as they are undoubtedly observed and seen here upon earth. And this, my meaning is to doe after a plaine and familiar sort: for as much as they, who hitherto wrote of this argument, have handled the same so sweetly, and

penned

penned it with ſo high a ſtyle, as they may ſeeme to any man for to have written bookes for Orators to read, rather than to the capacitie of plaine husbandmen for to practiſe. Firſt and foremoſt therefore, I will for the moſt part deale by Oracles, that is to ſay, ſententious Sawes, for to determine this queſtion in hand: concerning which, there are as many to be found in number, and thoſe as true in effect, as in any other patt and profeſſion of this our life whatſoever. And leaſt any man ſhould thinke it ſtrange, that I call theſe rules of Husbandrie, Oracles; who would take them for leſſe, conſidering how they proceed from Time, a god moſt certein, and are delivered and approoved by Experience, the trueſt prophet of all others. And begin I will with *Cato* firſt.

Chap. v.

The praiſe and commendation of Husbandmen: what things are to be required in the purchaſing or taking to ferme of houſe and land.

THe children (ſaith *Cato*) that are begotten by Husbandmen, proove moſt valiant, the hardieſt ſouldiers, and ſuch as thinke leaſt harme of all others. In buying of land, take heed you be not too hot and ægre upon the purchaſe. In the husbanding of ground, ſpare for no paine & travell; but in the purchaſing therof be you nothing forward: a thing over-bought, hath evermore repentance, and had I wiſt, attending upon it. They that are about a purchaſe, ought above all, to ſee how the ground is watered, what waies and avenues be about it, & what neighbours be neare unto it. Out of every one of theſe points, matters of great importance and deepe concluſions may be picked, and thoſe moſt certein and infallible. *Cato* addeth moreover and ſaith, That there would bee good regard had of the people confining, and other grounds bounding thereupon, whether they bee well liking, faire, and trim to ſee unto? For theſe bee his words, It is a good ſigne (quoth hee) that the ferme is well ſeated and in a commodious quarter, if all about looke well. *Attilius Regulus* (he who during the firſt Punicke warre was twiſe Conſull of Rome) was wont to ſay, That a man ſhould not purchaſe an unholeſome peece of land, were it never ſo rich and fruitfull; nor make choiſe of a barraine ſoile, were it never ſo healthie. Now as touching the healthfulneſſe of a place, a man may not alwaies conclude thereof by the colour and freſh hew of the inhabitants: for many times it falleth out, that thoſe who be uſed to peſtilent places, hold out well and have their health; yea and by their looks bewray no harme that they take. Moreover, ſome quarters and coaſts there be, which at ſome times of the yeare ſtand ſound and healthie enough: but I will count none holeſome, but ſuch as be healthfull all the year long. An ill peece of land is that, which putteth the lord thereof to paine, and with which he is forced to wreſtle for to have his health. *Cato* would have this point eſpecially to be conſidered, That the ſoile of a ferme (ſituate as hath been ſaid) be good of it ſelfe, and fertile: alſo, that neare unto it there be ſtore of labourers: and that it be not farre from a good and ſtrong towne: moreover, that it have ſufficient meanes for tranſporting of the commodities which it yeeldeth, either by veſſels upon water, or otherwiſe by waines upon the land. Furthermore, that the manour houſe be well built, and the land about it as well husbanded. Howbeit, herein I ſee many men to erre much, and greatly to be deceived: for they hold opinion, that the negligence and ill husbandry of the former lord, is good for him that ſhall purchaſe land and come after him. But I ſay, there is nothing more daungerous and diſadvantageous to the buyer, than land ſo left waſt and out of heart: and therefore *Cato* giveth good counſell, to purchaſe land of a good husband, and not raſhly and hand over head to deſpiſe and ſet light by the skill and knowledge of another. Who ſaith moreover, That as well land as men (which are of great charge and expence) how gainfull ſoever they may ſeeme to bee, yeeld not much profit in the end to the maſter *de claro*, when all counts be caſt and recknings made. He therfore judgeth, that the Vine yeeldeth the beſt revenue, of all commodities belonging to a ferme: and good reaſon he hath ſo to ſay, becauſe above all things he taketh order to cut off expence as much as may be. Next to it, hee reckoneth Hortyards, ſuch eſpecially as have water at commaund: and good cauſe why, provided alwaies that they lie under a good towne ſide. [In the third place he raungeth the Oſier plots, and after them Olive rewes:] then he counteth of medows, which our auncеſtors called Parata, as a man would ſay, Readie and Provided. The ſame *Cato* being asked, What was the moſt aſſured profit riſing out of land? made this anſwer, *To feed cattaile well:* beeing asked againe, What was the next? *Mary* (quoth hee) *to feed in a meane.* By which anſwers hee would ſeeme to conclude, that the

moſt certein and ſure revenue was that, which would coſt leaſt. Howbeit, this is not ſo generall a rule, but it may alter according to the diverſitie of places, and ſundrie occaſions occurrent. Hereunto alſo is to be referred another ſpeech of his, That a good husbandman ought to be a ſeller, [and not a buyer:] as alſo, That a man ſhould make ſpeed in his youth, and not delay to plant and ſtocke his ground; but not to build thereupon, before it bee well and throughly ſtored that way: and even then alſo, he ſhould not be forward thereto, but take leiſure ere hee be a builder: for it is the beſt thing in the world (according to the common proverbe) To make uſe and reape profit of other mens follies: provided alwaies, that a mans land bee not over-built, leaſt the expence of keeping all in good repaire, be chargeable and burdenſome. Now when there is a ſufficient and competent houſe builded thereupon, a good husband will uſe to repaire often thereunto, and take pleaſure ſo to doe: and verily a true ſaying it is, That the lords eye is far better for the land, than his heele. G H

Chap. VI.

How to chuſe a convenient place for to build a manour houſe in the countrey. Alſo certein rules obſerved in auncient time, as touching Husbandrie and tilling ground.

IN building upon a mans land, this mean and moderation is commended, That the houſe be anſwerable in proportion to the ground: for as it is a bad ſight to ſee a large domaine and circuit of ground without a ſufficient graunge or home-ſtall to it; ſo it is as great a folly to over-build the ſame, and to make a faire houſe where there is not land enough lying to it. Like as there were two men at one time living, who faulted diverſly in this behalfe; to wit, *L. Lucullus* and *Q. Scævola*, for the one was poſſeſſed of faire lands without competent building therto, whereas *Lucullus* contrariwiſe built a goodly houſe in the countrey, with little or no living adjoyning to it: in which regard, checked he was by the Cenſors, for ſweeping more floures than he ploughed lands. Now in building, there would be Art and cunning ſhewed: for even of late daies *C. Marius* (who had been ſeven times Conſull of Rome) was the laſt man that built an houſe within the territorie of the cape Miſenum, and he ſeated it ſo, as if he had pitched and fortified a camp right skilfully; in ſuch ſort, that when *Sylla* ſurnamed *Fælix*, [*i.* Happie] ſaw his manner of building, he gave out and ſaid, That all the reſt in compariſon of him, were blind beetles, and knew neither how to build nor to encampe. Well then, a houſe in the country would be ſet neither neare unto a fennie and dormant water, ne yet over-againſt the courſe and ſtreame of a running river. And yet, what ſaith *Homer* beſides to this purpoſe? The aire and miſts (quoth he, and that right truly) ariſing from a great river betimes in a morning before day-light, cannot chuſe but be ever cold and unholeſome. How then? mary if the countrey or climat be hot, an houſe muſt ſtand into the North; but in caſe the quarter be cold, it ought to affront the South: if the tract bee temperate betweene both, it ſhould lie open upon the Eaſt point, where the ſun riſeth at the Æquinoxes. I K 1 2 3

As touching the goodneſſe of the ſoile, and namely what ſignes and markes there be of it; although I may ſeeme to have ſufficiently ſpoken alreadie, in the diſcourſe which I had of the beſt kind of ground, yet I am content to ſubſcribe to other tokens thereof delivered by other men, and eſpecially by *Cato* in theſe words following: *When you ſee* (quoth hee) *growing upon any land, ſtore of Walwort, Skegtrees, Brambles, the little wild Bulbous, Crowtoes*, [called otherwiſe our ladies Cowſlips] *Claver-graſſe or Trifoile, Melilote, Oke, wild Pyrries, and Crabtrees; know yee, that theſe doe ſhew a ground good for Wheat, and ſuch like white-corne.* So doth alſo the blacke mould and that of aſhes colour, teſtifie no leſſe. Where there is ſtore of chalke or plaſtre, the ground is not ſo fit for corne; for all kind of chalke doth heat over-much, unleſſe the ſame be very leane. The like doth ſand alſo, if it be not paſſing fine and ſmall. And the effects aboveſaid are much more ſeene in the plaines and champaine vallies, than upon the hills and mountaines. Our anceſtours in old time thought it a principall point of Husbandrie, not to have overmuch ground about one graunge: for they ſuppoſed more profit grew by ſowing leſſe, and tilling it better: of which mind I perceive* *Virgil* was. And to ſay a truth, confeſſe we muſt needs, That theſe large enclo-ſures and great domaines held by privat perſons, have long ſince been the ruine of Italie, and of late daies have undone the provinces alſo thereto belonging. Six landlords there were and no more, that poſſeſſed the one moitie of all Africke, at what time as the Emperour *Nero* defeated L M

** Laudat ingentia rura, Exiguũ colito.*

and

A and put them to death. Where, by the way, I may not defraud *Cn. Pompeius* of the due glorie anſwerable to that greatneſſe of his, who never in all his life would purchaſe any ground that butted or bordered upon his owne land. *Mago* thought it no reaſon, but a very ungentle and unkind part for the buying of land, to ſell a manſion houſe: and in his conceit, it prejudiced much the weale-publicke. And verily this was the principall point that he recommended in the entrance of his treatiſe and rules ſet downe for Husbandrie: ſo as a man might perceive very evidently, that he required continuall reſidence upon the land. Next to theſe principles abovenamed, great regard would be had in chuſing of good and skilfull bayliffs of the Husbandrie, concerning whom *Cato* hath given many rules. For mine owne part, it ſhall ſuffice to ſay thus much onely, That the lord ought to love his bayliffe very well, and ſet him next to his heart: but himſelfe ſhould not let
B him know ſo much. Moreover, I hold it the worſt thing that is, to ſet ſlaves and condemned perſons in their gyves and chains, about tilling and husbanding of a ferme: neither do I like of any thing done by ſuch forlorne and hopeleſſe perſons; for lightly nothing thrives under their hand. I would put down one ſaying more of our ancient forefathers, but that haply it may ſeem a fond and raſh ſpeech, yea and altogither incredible, and that is this, *Nothing is leſſe profitable and expedient, than to labour a ground exceeding much, and to overtill it. L. Tarius Rufus*, a man of very baſe and low parentage deſcended, & yet advanced to the Conſular dignitie for his proweſſe in feats of armes, was otherwiſe very thriftie and ſparing, after the manner of the old world; inſomuch as partly by his niggardiſe and partly through the liberalitie of *Auguſtus Cæſar*, hee had gathered good togither amounting to the ſum of an hundred millions of Seſterces: all which maſſe of mo-
C ney, what with purchaſing land to land in the Picene countrey, and what with beſtowing ſuch a deale of husbandrie upon it, more ywis of a vaineglorie and oſtentation, than for any profit that he reaped thereby, he laid forth and ſpent every whit of that ſtock; inſomuch as hardly he could find any man that would take upon him to be his executour, or to accept ſimply of the inheritance. What ſhall we ſay then? or what good commeth of ſuch houſes or lands ſo chargeable, as that they are like to coſt a man his life, and that by famine? I hold therefore, that in all things a meane is beſt, and bringeth greateſt profit in the end. To till and husband ground well, is neceſſarie; to over-doe the ſame and to exceed, turneth more to the damage than the profit of the lord, unleſſe it were done by his owne children, or to maintain the charge of keeping ſuch hinds as otherwiſe muſt be found if they ſat ſtill and did nothing: for ſetting that cauſe aſide, it falleth
D out many times, that the gathering and inning of ſome harveſt (if a man count all the paines employed and the money of the purſe) is nothing beneficiall to the maſter. In like manner, Olives would not alwaies be tended and looked unto overmuch: neither do ſome grounds require much diligence, but are the worſe for ſuch attendance: as may be ſeen (by report) in Sicily; which is the cauſe that new commers thither for to be tenants, and to occupie thoſe lands, are many times deceived and put beſides their reckoning.

After what manner then ſhall we proceed in the Husbandrie of our land to moſt benefit and behoofe? Learne a rule out of this oracle or ſententious riddle, which goeth in this forme; *Malis bonis*, [*i.* Cheapeſt; Beſt.] But herein, me thinkes, good reaſon it is, that our old great grandfathers ſhould be defended and excuſed for holding theſe ſtraunge and obſcure paradoxes; they
E (I ſay) who by ſuch rules and precepts, tooke great care and paines to inſtruct us how to live. Would you know then what they meant by this word *Malis*? ſurely they underſtood thoſe that were cheapeſt and ſtood them in leaſt. The chiefe point of all their providence and forecaſt, was to goe the neareſt way to worke, and to bee at the ſmalleſt coſt: and no marveile; for who were they that gave out theſe thriftie precepts? even thoſe, who reproached a victorious Generall (and one who triumphed over the enemie) for having a cupbourd of ſilver plate weighing but ten pound: thoſe (I ſay) who if their bayliffs of husbandrie chaunced to die, whereby their lands in the countrey ſtood void, would make ſuit to be gone themſelves thither, and to returne to their owne fermes, leaving behind them the glory of all their victories by them atchieved: and to conclude, even thoſe who whiles they were employed in the conduct of armies, had their
F grounds looked unto and tilled at the charges of the common-weale, and had no other for their bayliffs than the noble Senators of Rome. From their mouths came theſe other oracles and wiſe ſentences following: An ill husband is he, who is forced to buy that, which his ferm might affourd him. As bad is that houſholder and maſter of a family, who doth that in the day which might be doh by night, unleſſe unſeaſonable weather drive him to it. A worſe than either of theſe is he, who

doth that upon work-daies which ſhould have been done on play daies or idle holidaies: but the G
worſt of all other is he, who when the weather is faire, will chuſe to work rather within cloſe houſe
than abroad in the open field. And here I cannot hold and rule my ſelfe, but I muſt needs alledge
one example out of auncient hiſtories, whereby it may bee underſtood, How it was an ordinarie
matter to commenſe actions and to maintaine pleas in open court before the bodie of the peo-
ple in the caſe of Husbandrie: as alſo in what ſort thoſe good Husbandmen of old time were
wont to defend their owne cauſe when they were brought into queſtion. And this was the caſe.
There was one *C. Furius Creſinus*, late a bondſlave, and newly enfraunchiſed, who after that hee
was ſet at libertie, purchaſed a very little peece of ground, out of which hee gathered much more
commoditie than all his neighbors about him out of their great and large poſſeſſions: whereup-
on he grew to be greatly envied and hated, inſomuch, as they charged him with indirect meanes, H
as if he had uſed ſorcerie, and by charmes and witch-craft drawne into his owne ground that en-
creaſe of fruits, which ſhould otherwiſe have growne in his neighbours fields. Thus upon com-
plaint and information given, he was preſented and endited, by *Spurius Albinus*, an Ædile Cu-
rule for the time being: and a day was ſet him downe peremptorily for his perſonall appearance
to anſwere the matter. He therefore fearing the worſt, and doubting that he ſhould be caſt to pay
ſome greevous fine; at what time as the Tribes were readie to give their voices, either to acquit
or condemne him, brought into the common place his plough, with other inſtruments and fur-
niture belonging to husbandrie: hee preſented likewiſe in the open face of the court, his owne
daughter, a luſtie ſtrong laſſe and big of bone; yea, and (as *Piſo* telleth the tale) well fed, and as
well clad: he ſhewed there (I ſay) his tooles and plough yrons of the beſt making, and kept in as
good order; maine and heavie coulters, ſtrong and tough ſpades, maſſie and weightie plough- I
ſhares, and withall his draught Oxen, full and faire. Now, when his courſe came to plead his own
» cauſe before the people, and to anſwere for himſelfe, thus he began and ſaid: My Maiſters (quoth
» he) you that are citizens of Rome, behold, theſe are the ſorceries, charmes, and all the inchaunt-
» ments that I uſe (pointing to his daughter, his Oxen, and furniture abovenamed:) I might beſides
» (quoth he) alledge mine owne travell and toile that I take, the earely riſing and late ſitting up ſo
» ordinarie with mee, the carefull watching that I uſually abide, and the painefull ſweats which I
» daily endure; but I am not able to repreſent theſe to your view, nor to bring them hither with
» me into this aſſemblie. The people no ſooner heard this plea of his, but with one voice they all
acquit him and declared him unguiltie, without any contradiction. By which example verily, a
man may ſoone ſee, that good Husbandrie goeth not all by much expence: but it is paines taking K
and carefull diligence that doth the deed. And hereupon came the old ſaid ſaw, ſo rife in everie
mans mouth, that The only thing to make ground moſt fertile and fruitfull, is the Maiſters Eye.
As for all other rules and precepts of Agriculture, reſpective to this or that peculiar point of hus-
bandrie, I will deliver them in their proper places accordingly. And in the meane time I will not
omit ſuch as be more generall, as they ſhall come into my mind and remembrance. Firſt & for-
moſt, there offereth it ſelfe unto me one above the reſt, whereof *Cato* is the Author, and which of
all others I hold to be moſt profitable and ſounding to civilitie, to wit, that in all our doings we
» aime at this, To have the love and good will of our neighbors: and that for many and ſufficient
» reaſons by him alleadged, which I ſuppoſe no man will make any doubt of. *Imprimis*, Hee giveth L
» a good caveat, That our ſervitours and people about us be not ſhrewd, but well ordered, and that
» none of our familie be ill diſpoſed to offer any wrong. *Item*, All good husbands agree in this,
» That nothing would be done too late & when the time is overhipt. And againe, That every work
» ſhould have the due & convenient ſeaſon: To the ſame effect there is a third admonition, name-
» ly, That when the opportunitie is once paſt, in vain we ſeeke to recall and recover it. As touching
a rotten and putrified ground, we have at large ſhewed alreadie how much *Cato* doth abhor and
curſe it. And yet he ceaſeth not to forewarne us of it, and beſides, to give us theſe rules follow-
ing. What worke ſoever may bee performed by a poore Aſſe, is thought to coſt little or nothing,
and to be done very cheape. Fearne or Brake will die at the root in two yeares, if you will not ſuf-
fer it to braunch and grow above ground: and this ſhall you hinder moſt effectually, in caſe you M
knap off the head of the firſt ſpring with a wand or walking ſtaffe: for the liquid juice dropping
downe from them, doth kill the root. It is commonly ſaid alſo, that if they be pulled up about the
Summer Sunneſtead, they will not come againe but die: as alſo, if they bee topt, or their heads
whipt off with a reed: or if they be cared up with the plough, ſo as there be a reed faſtened to the

ſhare.

A ſhare. Semblably,for to kill reeds,they give order to plough them up, with ſome Fearne likewiſe laid upon the ſhare. A ruſhie ground muſt be broken up and turned over & over with the broad ſpade: but if it be ſtonie,it would be digged with a mattocke or two tined forkes.Rough grounds and given to beare ſhrubs,if a man would ſtorke,the beſt way is to burne them up by the roots. If the place lie low,and be overmoiſt,the only meanes to make it ſound and drie, is to draine away the water by trenching.In caſe a ground do ſtand upon chalke or plaiſter,the ditches or trenches therein ſhould bee left wide open: but if the ſoile bee more looſe and not ſo faſt, they muſt bee ſtrengthened and kept up with quicke-ſet hedges,for feare of falling: or elſe they ought to bee made in ſuch ſort, as both the ſides thereof bee well bedded and couched, bearing out a bellie aſlope, and not digged plumbe downeright. Some would bee cloſed up above and made very
B ſtreight and narrow,for to run directly into others that are more wide and large: alſo,if occaſion doe ſo require, the bottome of their channell would bee paved with pebble, or laid with good gravell. As for the mouth and end therof(to wit,for entrance,and iſſue)they ought both of them to be fortified and underſet with two ſtones at either ſide, and a third laid croſſe over them. Laſt of all,if a ground run to wood and bee overgrowne therewith, *Democritus* hath taught us the meanes how to kill the ſame in this manner,Take Lupine flowers,let them be ſteeped one whole day in the juice of Hemlocke,and therewith beſprinckle and drench the roots of the ſhrubs that overrun the place,and they will die.

Chap. vii.

C *Sundrie ſorts of corne,and their ſeverall natures.*

NOw that wee have thus ſhewed the way how to prepare a field for to beare corne,it remaineth to declare the nature of Corne. And to ſpeake generally of all graine,there are two principall kinds therof,to wit,firſt Fourment,containing under it Wheat and Barley,and ſuch like:ſecondly,Pulſe,compriſing Beanes,Peaſe,Chiches,&c. The difference obſerved both in the one ſort and the other,is ſo evident and plaine, that needleſſe it is for me to uſe any words thereof. And as for the former kind called Fourment,it is devided alſo into ſundrie ſorts,according to the ſeverall ſeaſons wherein they bee ſowne.Firſt there is the Winter corne,which being ſowed about the ſetting of the ſtar Vergiliæ, *i.* in November, lieth all winter long in the ground, and there is nouriſhed,as for example,Wheat,Rie,and Barley.Secondly,Summer corne,which
D is put into the earth in Summer about the riſing of the foreſaid ſtar Vergilia, *i.* the Brood-hen,to wit,in May,namely,Millet,Panicke, Horminum,and Irio [two kinds of graine.] But note that I ſpeake here of the manner uſed in Italie. For otherwiſe in Greece and Aſia, they ſow all indifferently at the retrait or occultation of Vergiliæ.And to come again to our Italie,ſome grain there is which is ſowne there,both in Winter and Summer: as alſo,you ſhall have other corne ſowed in a third ſeaſon,to wit,in the Spring.Some there be who take for Spring-corne,Miſſet,Panicke, Lentils,cich Peaſe,and the graine wherof*Fourmentie is made.But Wheat,Barley,Beanes,Na- *Alica.
vews,Turneps,and Rapes,they hold for Sementina, *i.* to be ſowed at the proper and timely ſeaſon of ſeeds, *i.* in Autumne.In that kind of corne which comprehendeth Wheat,there is to be reckoned that graine which ſerveth for provender and forage,and is ſowne for beaſts,and namely,that
E which they call dredge or ballimong. Likewiſe,in the other kind,to wit,of Pulſe,the Vetches bee compriſed.But that which is good indifferently both for man and beaſt,is the Lupine. All ſorts of Pulſe called in Latine Legumina,unleſſe it be the Beane, have but one root apeece; and ſuch bee as hard as wood, and full of ſhoots,and thoſe devided into forked braunches: and the roots of the cich Peaſe run deepeſt into the ground. But all other corne under the name of Frumenta, have many ſmall fillets or ſtrings appendant to their roots,and otherwiſe branch not. As for Barley,it chitteth and begins to ſhew within ſeven daies after it is firſt ſowne. All ſorts of Pulſe appear above ground by the fourth day or the fift at the uttermoſt. And yet Beanes ordinarily do lie in the ground fifteen or twentie daies.Howſoever in Ægypt all Pulſe commeth up by the third day. In Barley, one end of the ſeed runneth to root downeward, and the other into blade, and that
F *bloumeth firſt. Now,if you would know which end ſerveth for the one and the other; certain it *No marvell being ſowed before winter.
is,that the bigger and thicker part of the grain yeeldeth root,and the ſmaller the greene blade.In all other ſeeds there is no ſuch diverſitie,for from one and the ſame end breaketh out both root and greene blade. All kind of corne carying ſpike or eare,called Frumenta,ſhew nothing but the greene blade during winter: howbeit,no ſooner commeth the ſpring,but they begin to grow up

into ſtraw, and to ſpindle upward pointwiſe, I meane all that bee of the Winter kind. But Millet G
and Panicke run up into an hollow ſtem full of knots and joints: and Seſama by it ſelfe into a kex
or hollow ſtemme in manner of fewell and ſuch like. The fruit or ſeed of all graine that is ſowne
or ſet, is contained either within eares, as wee ſee in (bearded) Wheat and Barley, and the ſame
is defended (as it were) with a pallaiſade of eales, diſpoſed ſquare in foure rankes; or, is encloſed
within long cods and huskes, as the Pulſe kind; or elſe lieth in little cups, as Seſame and Poppie.
Millet and Panicke onely put forth their fruit grape-wiſe and openly, without any partitions and
defenſes, ſo as their ſeed is expoſed to the little birds of the aire: for no otherwiſe are they defen-
ded, than within ſmall skins and thin huls. And as for Panicke, it taketh the name of certain pa-
nicles or chats hanging from the top thereof, whereby the head bendeth and leaneth downward,
as if it were weake and wearie of the burden. The ſtem or ſtalke therof groweth ſmaller and ſmal- H
ler, and pointed upward: inſomuch, as by little and little it runneth up in manner of a little ſprig
or ſion, and there you ſhall ſee a number of ſeeds or graines cluſtered together thicke, inſomuch
as they are ſometimes bunched with an head a good foot long. As touching the Millet, the head
thereof bearing ſeed round about, is bent likewiſe and curbed, beſet alſo with fringes (as it were)
of hairie fillets. But to returne to Panicke againe, there be ſundrie ſorts thereof: for ſome of it is
found with a tuft or bunch, from which depend certain ſmall cluſtered chats or panicles, and the
ſame alſo hath two knaps or heads, and this is called Mammoſum: as one would ſay, the Panicke
with bigs or dugs. Moreover, you ſhall have Panicke ſeed of ſundrie colours, white, blacke, and
red, yea, and purple. Of Myll or Myllet, there be diverſe ſorts of bread made in many places; but
of Panicke it is not ſo common: howbeit, there is no graine more ponderous and weightie than I
it, or which in the ſeething or baking ſwelleth and riſeth more; for, out of one Modius or pecke
thereof, there is ordinarily made ſixtie pound of dough for bread. Moreover, take but three ſex-
tares or quarts of it being ſteeped, and it will yeeld a meaſure called Modius of thicke grewell or
batter, called in Latine Puls. It is not fully tenne yeares, ſince there was a kind of *Millet brought
out of India into Italie, and the ſame was of colour blacke, the ſeed or graine in quantitie big and
faire, and for ſtem like unto a reed. It riſeth up in height ſeven foot: the ſtalkes are mightie and
great, ſome call them Lobæ or Phobæ. Of all ſorts of Corne it is moſt fruitfull & yeeldeth grea-
teſt encreaſe: for of one graine a man ſhall have three ſextars or quarts againe. But it loveth, yea
and ought to be ſowne in a moiſt ſoile.

* i. Turkiſh Millet.

Moreover, ſome kinds of ſpiked corne begin to ſpindle and gather eare at the third joint: o- K
thers at the fourth: but there it lieth as yet hidden and encloſed. Now as touching theſe joints,
Wheat beareth uſually foure. Beere Barley ſixe, and the common Sprit Barley eight, which is
well to be conſidered: for no corne uſeth to ſpier before it be fully knotted or jointed in manner
aboveſaid. And ſo ſoone as the ſaid ſpire ſheweth ſome hope of an eare, within foure or five daies
after at the moſt, they begin to bloume: and in as many daies ſpace, or little more, they will have
done, and ſhed their flowres. And yet I muſt needes ſay, that all ſorts of Barley are a ſeven-night
at the utmoſt in ſo doing. *Varro* ſaith, that in foure times nine daies this kinde of corne com-
meth to perfection: but it ought to ſtay nine moneths before it be ripe and readie for to be
reaped, or mowed downe. As for Beanes, after they be ſet or caſt into the ground, firſt they put
forth leafe, and afterward ſtalke, that ſhooteth up even without any partition of joynts or knots L
betweene. All other pulſe, beſides the Beane, have a more ſolide and woodie ſubſtance in their
ſtraw. Of which, the Cich peaſe, the Ervile, and Lentils, do ſpread forth in branches. And ſome
of them runne ſo low, that they creepe along the ground, unleſſe they be borne up and ſuppor-
ted with ſome props, as for example, Peaſe: which helpe, if they miſſe, they proue the worſe for
it. Of all manner of pulſe, the Beane alone and Lupine beare but one ſingle ſtalke a peece: the
reſt do branch into very ſmall ſprigs or tendrels. Howbeit none of them, but their ſtalke or ſtraw
is fiſtulous and hollow, in manner of reedes. Some pulſe put out leaves preſently from the roote:
others againe from the top or head only: Wheate and Barley both the one and the other: and
what corne ſoever ſtandeth upon a ſtalke, beareth one leafe in the head or top thereof. But the
leaves of Barley are rough, whereas in other corne they be ſmooth. Contrariwiſe, Beanes, Chi- M
ches and Peaſe, have many leaves. In Spiked corne, the leafe reſembleth that which groweth to
reedes: in Beanes they be round, and ſo likewiſe in the moſt kinds of pulſe. Howbeit, in Peaſe and
Ervile we ſee they be ſomewhat longer. The leaves of Faſels or Kidney beanes are ribbed and full
of veines: of Seſama and *Irio, they be red and reſemble bloud. The Lupines onely and the

* i. Turkiſh corne.

Poppies

Poppies doe ſhed their leaves. All pulſe is long in the bloome, and namely, Ervile and the Cich peaſe: but Beanes continue longeſt, even for the ſpace of fortie daies togither. Howbeit, every ſingle ſtalke beareth not bloume ſo long: but thus it is, as one hath done and given over, another beginneth afreſh. Neither bloumeth the whole field all at once, as ſpiked corne doth. Alſo, all kinds of Pulſe doe cod at ſundrie times, and not upon the ſame day: beginning firſt at the bottome, and ſo likewiſe the flower riſeth up higher by little and little. All corne growing in ſpike or eare, ſo ſoone as it hath done blouming, waxeth big and ſtrong, and commeth to the maturitie within fortie daies at the fartheſt, ſo doe Beanes alſo: but the cich peaſe receiveth her full perfection in very few daies: for from the time that it was firſt ſowed, it groweth to bee ripe in fortie daies. Myllet, Panicke, Seſame, and all Summer corne, have their full ripeneſſe fortie daies after their blouming. But herein there is great diverſitie, according to the clime and the ſoile: in which reſpects corne ripeneth ſooner or later. For in Ægypt, Barly is readie to be reaped in the ſixt month after it was ſowed, and Wheat in the ſeventh: but in the region of Hellas in Greece, the Barley tarieth ſeven months; & in Peloponneſus or Morea, eight. As for Wheat and ſuch like hard corne, longer it is ere it be ripe and ready for the ſycle. All corne that groweth aloft upon a ſtalke or ſtraw, beareth the graines arraunged ſpike-wiſe, and as if they were plaited and braided like a border of haire. In Beane ſtalkes, and other ſuch like Pulſe, the cods grow in alternative courſe, ſome on the right ſide, others on the left, in order. Wheat & ſuch like ſpiked corne, withſtand the Winter cold better than Pulſe: but theſe yeeld a ſtronger food, and fill the bellie ſooner. Wheat, Rie, and ſuch like graine, are well lapped within many tunicles. Barley for the moſt part lieth bare and naked: ſo doth Arinca, [*i.* a kind of Rice or Amel-corne] and Oats eſpecially. The ſtraw of Wheat and Rie is commonly taller than that of Barley. But the eiles of Barley are more rough and prickie than thoſe of the other. Pol-Wheat, both red and white, yea, and Barley alſo is threſhed and driven out of the huske upon a floore; and being thus threſhed clean and pure, it is either ground or ſowne againe, without any parching or drying in a furnace. Contrariwiſe, the Beare corne or bearded Wheat, Far, Millet, and Panicke, cannot poſſibly be made cleane, unleſſe they be firſt ſendged and ſo dried. Theſe ſorts of graine therefore uſe to bee ſowed raw and rude with their very huls: like as the Beare corne or bearded Far, men are wont to keepe ſtill encloſed within the huske againſt ſeed time, and never parch or drie it at the fire. Of all the ſorts of graine before rehearſed, Barley is the lighteſt; for a Modius or pecke thereof ſeldome weigheth above fifteene pounds: whereas the like meaſure of Beanes poiſeth two and twentie. The bearded corne Far is yet more ponderous than it: and Wheat more than all the reſt. In Ægypt they uſe to make certain fourmentie meat or naked groats of a kind of Rice or white Amel-corne, called Olyra; which is among them holden for the third ſort of Spike corne. In Gaule likewiſe they have a kind of fourmentie corn or gurts by themſelves, named in their language Brance; and with us in Italie and about Rome, Sandalum: this graine is of all others moſt neat and faire, and this ſingular propertie it hath beſides different from the reſt, That ordinarily in every meaſure called Modius, it yeeldeth more bread by foure pound weight, than any other corne husked and dreſſed in manner aforeſaid. *Verrius* reporteth, That the people of Rome for three hundred years together, uſed no other food than the groats made of common Wheat. And as touching Wheat, there be many ſorts thereof, diſtinguiſhed by the names of the regions and countries where they be found growing. Howbeit, for my part I thinke verily, that there is no Wheat in the world comparable to ours here in Italie, for it ſurpaſſeth all others both in whiteneſſe and alſo in weight: by which two markes eſpecially, as it is knowne from the reſt, ſo it is reputed for the verie beſt. And yet if you take the Wheat growing in the mountaine countries of Italie, the beſt haply of forraine regions may match it, and that is the Wheat of Bœotia; the principall of all others, next to it, is that which groweth in Sicilie; and then that of Affricke may bee raunged in the laſt place: in a third ranke is to be reckoned the Thracian and Syrian Wheat; and after them the Ægyptian, in regard of their weight that it carieth. Now theſe degrees of weight wee gather by the proportion aſſigned to champions and wreſtlars, whoſe allowance was much like to the liurie given to labouring horſes, and as much in manner would their paunches both require and receive: for according as they could eat of the one ſort more meaſures than of the other, *ſo aroſe theſe diſtinct degrees in the weight aboveſaid. The Greekes make great account of the Wheat growing by Pontus, and highly commend it: but this never came into Italie, neither know wee what it is. The ſame Grecians preferred before all other graine, theſe three ſorts, to wit, Dracontias,

* For whereas of the Athenian Wheat, five demie ſextars, (*i.* two quarts and a halfe) were but ſufficient; three would ſerve and content them of the Bæotian, *i.* a quart and a halfe: whereby it was collected howmuch weightier this was than that.

tias, Strangias, and Selinuſium; eſteeming the goodneſſe of the corne by the thickneſſe and bigneſſe of the ſtraw, and attributing theſe three kinds by that ſigne and argument, to the goodneſſe and riches of the ſoile: and therefore they preſcribed to ſow this corne in a fat and battle ground. But the lighteſt in weight & pooreſt in ſubſtance, becauſe it required much nutriment, they appointed to be ſowed in moiſt places. Of this opinion and judgement were the auncient Greekes, during the reigne of *Alexander* the Great, at what time as Greece was in the flowre and heigth of her glorie, as having the monarchie and ſoveraigntie over the whole world. Howbeit, before his death 145 yeares or thereabout, *Sophocles* the Poet in a Tragœdie entituled Triptolemus, praiſed the Italian wheat above all other; for in effect thus he ſaith word for word:

Et fortunatam Italiam frumento canére candido.

And Italie, a land (I ſay) ſo happie and ſo bleſt,
Where ſtand the fields all hoare and gray, with white wheat of the beſt.

And in very truth, our Italian wheat at this day carrieth the name alone in that regard. I wonder therefore ſo much the more at the moderne Greekes of late time, who made no mention at all of this our wheat. Now at this preſent, of all thoſe kinds of outlandiſh wheat which are tranſported by ſea into Italy, the lighteſt is that which commeth out of Fraunce, and Cherſoneſus, [*i.* the ſtreights of Callipolis] for a Modius or pecke therof conteineth not above twentie pound weight, weigh the very graine it ſelfe as it groweth uncleanſed, huske & all. The Sardinian wheat is more weightie than it by halfe a pound in a Modius. And that of Alexandria exceedeth the French, halfe a pound and * one third part, in every meaſure before-named. And this is the very poiſe alſo of the Sicilian wheat. The Bœotian is yet a full pound heavier: and that of Africk as much and * three fourth parts of a pound more. In Lombardie, and that tract of Italy beyond the river Po, I know full well that a Modius of their wheat weighed 25 pounds; and about Cluſium, ſix and twentie. But be the corne whatſoever it will, this is the ordinarie proportion by the courſe of Nature, That being made into downright houſhold bread for ſouldiers and to ſerve the campe, it ought to weigh as much as it did in corn, & one third part over and above. As alſo this is a rule, That the beſt wheat is that, which to every Modius will take and drinke up a gallon of water, ere it be made dough. And yet ſome kinds of wheat there be, that will yeeld the full weight aforeſaid in bread, and never count the water going thereto, and namely that which commeth out of the Balear Iſlands; for a Modius of that wheat yeeldeth in bread 30 pound weight: yet otherwhiles it falleth out in ſome kinds of wheat (being blended two ſorts togither, as namely that of Cyprus and Alexandria, wherof neither exceed little or nothing more than 20 pound weight to the Modius) that the bread made therof will ariſe to the ordinarie proportion: for the Cyprian wheat is not bright, but brown and duskiſh, and therfore maketh a black kind of bread; in which regard the Alexandrian wheat, which is faire and white, is mixed with it: and ſo both togither doe yeeld in bread 25 pound weight. The wheat of Thebes addeth a ſurpluſage thereto of one pound.

* *i.* 4 ounces.

* *i.* 9 ounces.

As for the manner of working and kneading dough, I like not their faſhions who take ſea-water for that purpoſe; as moſt doe that inhabit the ſea coaſts, thinking thereby to ſave the charges of ſalt; for I hold this very hurtfull and daungerous: neither do I thinke, that upon any other cauſe, mens bodies are made more ſubject to maladies, than by this meanes. In Fraunce and Spaine, when the Bruers have ſteeped their wheat or ſrument in water, and maſht it for their * drinke of divers ſorts, as heretofore hath been ſhewed; they take the * skum or froth that gathereth aloft by the working of the woort, and uſe the ſame in ſtead of leven for to make their bread; which is the reaſon that their bread is lighter and more houved up than any other.

* *Zythum & Curmi.*

* Yeſt or barm.

Moreover, there is a great difference in wheat, by reaſon of the ſtraw or ſtalke that beareth it: for the thicker that it is and more full, the better is the corne taken to be. The Thracian wheat is encloſed and well clad (as it were) with many tunicles or coats: throughly provided by that meanes (and good cauſe why) to reſiſt the exceſſive cold of that climat; which gave the Thracians juſt occaſion alſo to caſt about and deviſe to have a kind of wheat that remaineth upon the ground not above three moneths, by reaſon that the ſnow over-ſpreadeth the face of the earth all the yeare beſides: and verily this kind of corne is come into other parts of the world, and lightly within three moneths after that it is ſowed, you ſhall have it readie to bee reaped: A pra-

ctiſe

A ctise well knowne all the Alps over, and in other cold and winterly regions, where (by the report of the inhabitants) this kind of corne doth wondrous well, and none prospereth better or groweth more ranke than it. Over and besides, there is another kind of wheat that putteth up from every root one stalke and no more in any place whatsoever: the manner is to sow it in no ground but that which is light, and it never misseth. Also about the Thracian gulfe, there is wheat that within fortie daies after the sowing, will be ripe, and thereupon it is called the Two-month wheat. And would you hear a wonder? there is no wheat more weightie than it; and besides, it yeeldeth no bran at all. In Sicilie and Achaia both, there is great use thereof, and namely among the mountainers of those two countries. Much seeking also there is after that corne in the Iland Euboea, about Caystus. See how much *Columella* was deceived, who thought that there was not to
B be found so much as any kind of three-moneth wheat: whereas it is plaine, that such hath been of old and time out of mind. The Greekes also have a proper name for it, and call it Trimenon. Furthermore, it is reported, that in the countrey Bactriana, there is some corne of that bignesse, that every graine is full as much as one of the eares of ours.

But to returne againe to our Husbandrie; of all spiked corne, Barley is sowed first: but I purpose to set downe the very just time and season appropriate to ech kind, according to the severall nature of every sort, which my meaning also is to declare. Meane while I cannot omit, that there is among the Indians, barley both sowne and also wild, whereof they make the best bread that they have. As for us Italians (to say a truth) we set most store by Rice, whereof (being husked and cleansed) we make grotes, like for all the world to those which other men besides doe make of
C barley husked. The leaves verily that this graine Rice doth beare, be pulpous and fleshie, resembling Porret or Leekes, but that they be broader: the stem groweth a cubit high, the flower is of purple colour, and the root round like a jem or pearle.

Barley [husked] was the most auncient meat in old time, as may appeare by the ordinarie custome of the Atheniens (according to the testimonie of *Menander*) as also by the addition or surname given to sword-fencers, who upon their allowance or pension given them in barly, were called Hordearij, [*i.* Barley-men.] The ordinarie drie grout or meale also Polenta, which the Greekes so highly commend, was made of nothing els but of barley: and the preparing thereof was after sundrie waies. The manner that the Greekes used, was first to steepe the barley in water, and give it one nights drying; the morrow after, they parched or fried it, and then ground it in
D a mill. Others there be, who (when it is well fried and parched hard) besprinckle it once againe with a little water, and then drie it before it be ground. There are some againe, who take the ears of barley when they are green, beat and drive the corne out, and while it is fresh and new, cleanse it pure; which done, they infuse it in water, and while it is wet, bray it in a mortar: then, they wash it well in osier paniers, and so let the water run from it; and being dried in the sunne, they pound or stampe it againe; and beeing throughly husked and cleansed, grind it into meale as is aforesaid. Now when it is thus prepared one way or other, to twentie pound of this barley they put of Line seed three pound, of Coriander seed halfe a pound, of salt about * two ounces and two drams: and after they have parched them all well, they blend them togither and grind them in a querne. They that would have this meale to keepe long, put up into new earthen vessels all to-
E gither both flower and bran. But in Italie they never use to steepe or soke it in water, but presently parch it, and grind it small into a fine meale, putting thereto the former ingredients, and the graine of Miller besides.

* *Acetabulum.*

As for bread of barley, so much used of our forefathers in old time, the posteritie that lived after, found to be naught and condemned it: in such sort, as they allowed it for provender only to feed their beasts and cattaile with. But in stead thereof came up the use of * husked barley, to bee sodden for grewell; so highly commended as a most nutritive and strong meat; and withall, passing holesome for mans bodie: in so much as *Hippocrates* (who for skill and knowledge was the prince of all Physicians) hath written one whole booke in the praises onely of it. Now the best Ptisana or husked barley, is that which commeth from Vtica. As for that which we have from
F Ægypt, it is made of the flat barley which groweth upon the eare in two rankes or sides only. *Turannius* saith, That in the realms of Granade, Andalusia, and Africk, the barley whereof the said Ptisane is made, is smooth and naked in the eare without eiles or beard at all. Hee also is of opinion, that Rice and the graine Olyra, are all one. The manner of preparing husked barley and making Ptisana is so commonly knowne, that I need not to say a word thereof.

* *Ptisana.*

As

As for Tragum, it is a kind of Ptisane, made of Wheat, after the same order that the former of Barley. Howbeit, there is none of it to bee found but in Ægypt and Campaine. Touching Starch-flower called Amylum, it may be made of all kinds of wheat, and of the fine corne Siligo, *i.* Winter wheat: but the principall is that which they make of the three-month or Summer wheat. Wee are beholden to the Iſland Chios for the invention of Starch: and even at this day, the very beſt is that which commeth from thence: called it is in Greeke Amylum, becauſe it never came into the mill, nor was ground upon ſtones. The next to it in goodneſſe, is made of a certaine Summer wheat that is nothing ponderous and weightie. The way to make it, is to ſteepe the wheat within certaine cooperie veſſels made of wood, in freſh water ſo much as will cover it well. But it would not bee forgotten, that the water muſt bee chaunged five times in a day: and if it were ſo ſerved alſo in the night, it would bee the better, to the end, that beeing thus ſoaked and ſoftened, it might bee well mixed and incorporated, yea, and reſolved (as it were) into a kind of paſt, before that it become ſoure and bitter. This being done, it muſt bee laid to drie either upon linnen cloths, or elſe in twiggen paniers, that the liquor which is therein may draine away: afterwards upon tiles, beſmeared over with ſome leaven, it is poured forth to take the Sunne, to drie and harden againſt it. After the Chian Starch, that of Candie is moſt eſteemed and liked of: and laſtly, that which commeth out of Ægypt. The good Starch ought to bee light, ſmooth, and even, and withall, freſh made: for thoſe properties hath *Cato* ſet downe alreadie.

To returne againe unto our Barley: the meale thereof is of great uſe here with us in Phyſicke. And that which more is, a ſtraunge effect it worketh in Horſes, Aſſes, and ſuch like labouring beaſts: for take Barley when it is dried and hardened at the fire, grind it to meale, reduce it into a paſte, and make thereof gobbets: let theſe bee put downe by a mans hand into their bellie, after the manner of cramming Pullen, and you ſhall ſoone ſee, that this food and manner of feeding, ſhall make the beaſts more ſtrong and luſtie, and their fleſh more faſt and compact.

As for Barley eares, ſome there bee which have but two rankes or rewes: others againe have more, even to the number of ſixe. In the verie graine alſo there is much difference: for there bee many of them longer than other, lighter, ſhorter, rounder, whiter, blacker, and laſt of all, enclining to a reddiſh or purple colour. This is the worſt of all others for to make drie Grout or Polenta: and as for the white, it is beſt for that purpoſe, but will not abide any tempeſtuous or hard weather. And to ſay a truth, of all corne, Barley is the ſofteſt and tendereſt, and will leaſt endure any hardneſſe: It would not bee ſowed, but in a drie and fine ground, laid light, and brought into temper: howbeit, good it muſt bee, and well in heart. The chaffe and pugs that come of Barley, is ſuppoſed to bee as good as the beſt: but for ſtraw it hath no fellow, eſpecially to make litter of. Moreover, in this regard, Barley of all other graine, is leaſt ſubject unto blaſting, for lightly it is cut downe before that Wheat is mieldewed. And therefore it is, That the wiſer ſort of Husbandmen in the countrey, ſow no more Wheat than will ſerve for the proviſion of their houſe onely. Furthermore, they ſay, that Barley is ſowed with the rake, namely, when the mould lightly covereth it: and therefore it commeth up ſooneſt, and bringeth moſt encreaſe and plentie. That which is gathered at Carthage in Spaine, within the moneth of Aprill, is ſowed the verie ſame moneth in Celtiberia, ſo as in one yeare it yeeldeth two crops. It is no ſooner ripe, but they make greater haſt to cut it downe, and to inne it, than any other corne: for the ſtraw is verie brittle, and the huske which containeth the graine is as thin and ſmall. To conclude, it is thought to yeeld the better groats if it be taken whiles it is ſomewhat greene, rather than if it ſhould have the full ripeneſſe.

Chap. VIII.

That all kinds of Wheat or Fourmentie corne grow not indifferently in everie place. Alſo, of other ſorts of corne in the Levant or Eaſt countries.

YOu ſhall not find in all places the ſame kinds of Wheat: and where you meet with the very ſame, yet they beare not one name, but have ſundrie appellations. The red bearded wheat named in Latine Far, and which in old time they called Adoreum; the winter wheat Siligo, and the

the ordinarie white Fourmentie wheat Triticum, are the commoneſt of all others. And indeed theſe grow all in moſt countries. As for Arinca, it loveth Gaule beſt, and that is the native and proper countrey for it: howbeit, there is plentie thereof in Italie alſo. As for Zea, Olyra, and Typhe, they be ſundrie ſorts of Wheat and Rie peculiar and appropriate to Ægypt, Syria, Cilicia, Aſia, and Greece. The Ægyptians make of their Wheat a kind of flower or ſifted meale, but nothing comparable to the Italian. They that uſe Zea or Spelt, have not the fine red wheat Far. And yet we are ſtored therewith in Italie, and moſt of all in Campaine, where it is called by the general name of Seed. Which name no doubt was given unto it for excellencie and ſingularitie, as ſhall be ſhewed anone more at large. This is the very graine for which *Homer* the Poet called the earth ζείδωρος ἄρουρα, *i.* yeelding the corne Zea: and not becauſe ſhee giveth life to all living creatures, as ſome would have to bee meant by that Epithete. Thereof is made alſo a kind of ſtarch, but groſſer than the former, whereof we ſpake before: for no difference is there elſe. Of all kinds of wheat, Far (which is taken for the red, bearded wheat) is moſt hardie & beſt reſiſteth winter cold: it will well abide the coldeſt ſoile that is, and that which is leaſt laboured and tilled: it may endure alſo hote and drie places: it yeelded the firſt food and meat to our auncient forefathers in Latium; as may appeare by this good argument, that publicke preſents and rewards by way of remuneration were given of Far, which they called Adorea, as hath bin ſaid before. Moreover, that the Romanes for a long time lived of a kind of batter or gruell made of meale ſodden, and not of bread, is very evident by old records and Chronicles: for even at this day ſuch thicke gruels or pottage be called Pulmentaria in Latine. And *Ennius*, a moſt auncient Poet, when he would expreſſe the famin of a citie that had endured long ſiege, reporteth, That the parents tooke by force from their children their ſops, notwithſtanding they cried pitteouſly for verie hunger. Moreover, even in our time wherein we live, the ſacred and ceremonious feaſts which we obſerve in memoriall of our Birth daies and Nativitie, ſtandeth much upon Furmentie, Gruell, Fritters, and Pancakes. It ſeemeth alſo, that our gruels and ſuch like pottage were as much unknowne to Greekes, as their Polenta or dried groa̅s were ſtrange to us here in Italie. There is no corne more hungrie and greedie of nouriſhment, than Seed [Wheat;] or that draweth more vertue & fat out of the earth for nutriment. As touching the winter graine, called in Latine Siligo, I may be bold to ſay, it is the daintieſt and moſt delicate wheat that is, for whiteneſſe, mildneſſe, and lightneſſe. It agreeth well with moiſt countries, ſuch as Italie is, & that part of Gaule called Comata, *i.* Lum-
D bardie. Beyond the Alpes alſo in Savoy onely, and the territorie of the Meninians, it will endure and hold the owne very well: marie, in other parts of that countrey, within two yeares it turneth into the common wheat. The onely remedie therefore, is to chuſe foorth the heavieſt and weightieſt cornes, and them to ſow.

Chap. IX.

Of Paſtrie, of Grinding, and of Meale.

THe beſt manchet bread for to ſerve the table, is made of the winter white wheat Siligo: and the moſt excellent workes of paſtrie likewiſe are wrought thereof. And yet in Italie, it paſ-
E ſeth all the reſt in caſe that of Campaine bee blended with another ſort which groweth about Piſæ: for the wheat of Campaine is redder, but this of Piſæ whiter: and more weightie it is, if it come from a chalkie ground, or have chalke mingled among. Moreover, this is the ordinarie proportion, that of the very pure corne of Campaine wheat, which they call guelded, *i.* wel husked & cleanſed, a meaſure named Modius ſhould yeeld foure ſextars or quarts of fine meale: but of the vulgar and common graine, which is not ſo guelded, five ſextares, and halfe a Modius beſides of boulted flower: and for a courſer houſhold bread, which they call the ſecond bread, foure ſextars of meale, and as many of brans. Alſo of the Piſane wheat, one Modius ſhould yeeld five ſextars of good meale, and the reſt equall to the former. As for the Cluſine and Aretine wheat, in every Modius it anſwereth againe ſixe ſextars of meale, that is to ſay, one more than the
F reſt: otherwiſe they bee all alike. Now if you liſt to raunge and boult it for corke flower to make bread, yee ſhall have of manchet ſixteene pound, of courſe houſhold bread three, & halfe a Modius of brans. But this proportion doth not alwaies hold, for it altereth according to the good or bad grinding upon the mill. For that which is ground drie, rendereth againe more meale: but if it be wet or beſprinckled with ſalt water, it maketh the fairer meale, and fuller of fine flower: and

then

then ſhall yee have more goe away in brans. As for the word Farina in Latine, *i.* Meale, it is deriued of Far, which in old time was the beſt and fineſt red wheat, as may appeare by the very name that it carieth. Finally, a Modius of meale comming of the French Siligo, called Blancheen or Ble-blanch, maketh in bread two and twentie pound weight: but of our Italian, three or foure pound more in bread pan-baked: for what corne ſoever it bee, there muſt bee allowance of two pound vantage over and above, for oven-baked bread.

Chap. X.

Of the meale called Similago: of the white flower Siligo. Of other ſorts of meale: and of the manner of baking.

THe beſt meale of that kind, which they call in Latine Similago, is made of the common wheat. If the corne come out of Affricke, it yeeldeth ordinarily for every Modius, halfe ſo much in ordinarie meale, and five ſextares beſides of flower called Pollen. [For that is the Latine tearme which they uſe in the fineſt of the common wheat Triticum, proportionable to that which in the other winter wheat, Siligo they call Flos. And great uſe hereof there is in coppersmiths forges, and in worke-houſes where paper is made.] Over and beſides, of courſer grodgeons for browne bread foure ſextars, and as much of brans. Moreover, the ordinarie proportion goeth thus, that of one Modius of the fine meale Similago, there ſhould bee made 122 loves of bread: and that a Modius of the pure flower of Siligo, ſhould yeeld 117. As touching the price, thus it goeth commonly in the market one year with another, when corne is at a reaſonable and indifferent rate: A Modius of downe right meale is worth *40 Aſſes: but if the meale bee ſifted and raunged from the groſſe brans untill it be Similago, it will coſt eight Aſſes more: and if it be boulted yet finer to the nature of the fine flower Siligo, the over-deale in the price will bee double. Another diſtinction or difference there was knowne of this proportion, when a Modius comming of wheat of Similago, was ſeene to anſwer 17 pound in bread: and as much of wheat flower called Pollen, 30 pound and foure ounces: beſides, for ſecond houſhold bread, two pound and a halfe; and of the courſeſt or browneſt, as many, and ſixe Sextars over and above of brannes.

*i. 2ſh. 6d.

But to returne to our winter white wheat called Siligo, it never ripeneth kindly and all togither, as other corne doth: and for that it is ſo tender and tickliſh, as that no corne will leſſe abide delay and tarie on worſe, great heed muſt be taken thereof; for ſo ſoone as any is ripe, preſently the ſeed ſheddeth and falleth out of the eare. Howbeit, leſſe daunger is it ſubject unto whiles it ſtandeth in the field, than other kinds of wheat, for it beareth alwaies an upright ſpike or eare: neither will it hold and retaine that mildew, which blaſteth corne ſo much, and turneth it into blacke powder. As for that kind of corne which they call Arinca, it maketh the ſweeteſt bread: the graine it ſelfe is more faſt and full than the fine red wheat Far: it carieth a bigger eare, and is beſides more ponderous and weightie. Seldome is it ſeene, that a Modius of this graine maketh full ſixteen pounds. In Greece they have much adoe with it, to threſh it cleane and falter it from the hulls and eales. For which cauſe *Homer* ſaith, That they were wont to give it as provender to horſes, and ſuch labouring garrons: and the very ſame it is which he calleth Olyra. Howbeit this corne in Ægypt goeth out eaſily under the flaile, is better to grind, and withall yeeldeth better, and is more fruitfull. The red wheat called Far, is polled wheat [in Ægypt] and carieth no beard or eales about it. So is the white winter wheat Siligo, ſave only that which is named Laconica. To theſe may be adjoyned other kinds alſo, to wit, *Bromos, the poll wheat Siligo, (differing from all the other of that name) and Tragos: ſtraungers all, brought from the Levant or Eaſt parts, and reſembling Rice every one. Typhe likewiſe is of the ſame kind, whereof in Italy and this part of the world, is made that husksd corne which goeth among us for Rice, for it turneth into it. The Greekes have a kind of wheat called Zea or Spelt: and it is commonly ſaid, that both it and Typhæ (conſidering that they uſe to degenerate and proove baſtard) will turne to their kind againe and become wheat, if they be husked before a man ſow them: howbeit this chaunge will not be ſeene preſently, nor before the third yeere. As touching our commmon wheat, there is no graine more fruitfull than it: this gift hath Nature endued it withall, becauſe ſhee meant thereby to nouriſh mankind moſt; for one Modius therof ſowne, if the ſoile be good and agreeable thereto (ſuch as lyeth about Bizacium, the champian countrey of Affricke) wild yeeld an hundred

K

L

M

*Some take it for a kind of Barley, or rather Otes.

hundred and fiftie fold againe. The Procurator generall of that province under *Auguſtus Cæſar*, ſent from thence unto him one plant thereof (a wondrous thing and incredible to be reported) which had little under 400 ſtrawes ſpringing from one graine, & meeting all in one and the ſame root: as it appeareth upon records by the letters ſent, teſtifying no leſſe. Likewiſe to the Emperour *Nero* he ſent 340 ſtrawes out of the ſame countrey, riſing all from one onely corne. But to goe no farther than to Sicilie; within the territorie about Leontium, there have been certaine fields knowne, wherein one graine putteth forth no fewer than a hundred ſtalkes with eares upon them: and not there onely, but alſo in many other parts of that Iſland. And this is ordinarie throughout all the kingdome of Granade, and Andaluſia in Spaine. But above all, the land of Ægypt may make boaſt in rendring ſuch intereſt to the husbandmen. Moreover, of all thoſe kinds of wheat which are ſo plentifull, there is principall account made of that which braunCheth; as alſo of another which men call Centegranum, *i.* the wheat that beareth 100 graines.

To leave this kind of graine, and to come to Pulſe: there hath been found in Italie, and goe no farther, one beane ſtalke laden with an hundred beanes. Touching Summer corne, to wit, Seſama, Millet, and Panicke, we have alreadie ſpoken. As for Seſama, it commeth from the Indians, whereof they make a certaine kind of oile. The colour of this graine is white. Like unto it there is another grain called Eryſinum, which is rife in Aſia and Greece: and I would ſay it were the very ſame, that with us in Latine is named Irio, but that it is more oleous and fattie; and indeed to be counted a medicinable or Phyſicall plant, rather than a kind of corne. Of the ſame nature, is that which the Greekes call Hormium: it reſembleth Cumin, and is uſually ſowed with Seſama: howbeit no beaſt will eat thereof while it is greene, no more than they doe of Irio aforeſaid.

To come now to the manner of huſking and cleanſing of corn: the feat is not ſo eaſily done in all, as in ſome; for in Tuſcane, they take the eares of their red wheat called Far, when they be parched and dried at the fire, they pound or bray them with a peſtill headed at the nether end with yron, or elſe fiſtulous and hollow within, yet bound about with a hoope or ring of yron, and the ſame withinforth toothed in manner of a ſtarre; ſo as if they be not heedfull in the ſtamping, the yron-worke at the peſtill end will either cut the cornes in twaine, or els bruſe and break them cleane. In Italie (for the moſt part) they uſe a rude or plain peſtill, not headed with yron, to huske and dreſſe their corne; or els certaine wheels that are turned and driven apace with water, which going very ſwift doe alſo grind the ſaid corne. But ſince wee are falne into this treatiſe concerning huſking and grinding of corne, it ſhall not be amiſſe for to ſet downe the opinion and reſolution of *Mago* in this behalfe: Firſt, for common wheat he giveth order, that it be well ſteeped and ſoked in good ſtore of water; afterwards, to be rid from the hulls and eiles that it hath, in a mortar: which done, it ought to be dried in the ſunne, and followed a ſecond time with a peſtill. In like manner (ſaith he) ſhould barley be uſed: howbeit, two Sextars or quarts of water will be ſufficient to beſprinkle and wet twentie Sextars of barley. As for Lentils, hee would have them firſt parched and dried, and then lightly punned or ſtamped togither with brans: or els to put unto twentie Sextars thereof, a fragment or peece of a broken ſemeld brick, and halfe a Modius or pecke of ſand. Ervile would be clenſed or huſked as Lentils be: but Seſama, after it hath been infuſed or ſoked in hote water, hee ſaith, ought to bee laid abroad a ſunning; then to be rubbed hard togither; afterwards to be put into cold water and therewith covered, ſo as the hulls or chaffs doe flote and ſwim aloft: which done, to be laid forth a ſecond time in the ſunne upon linnen clothes, for to drie. Now if all this be not done one thing after another and diſpatched with the more ſpeed and haſt, it will ſoone vinew or catch a mouldineſſe, and beſides looſe the bright native hew, and looke wan and of a leaden colour. Now, ſay that corne be cleanſed and huſked, ſome one way and ſome another, it is ground afterwards in divers ſorts. If the eares be bolted by themſelves alone for goldſmiths worke, the chaffe comming thereof is called in Latine, Acus; but if it be threſhed and beaten upon a paved floore, eare, ſtraw, and all together (as in moſt parts of the world they uſe to doe, for to fodder cattaile or give in proyender to horſes) then it is tearmed Palea: but the refuſe or chaffe remaining after that Panicke or Seſama bee cleanſed, they call in Latine Appluda, howſoever in other countries it be otherwiſe named.

To ſpeake more particularly of Millet, there is great ſtore thereof in Campaine, and there they ſet much by it; for of it they make a kind of white gruell or potage: alſo the bread thereof is paſſing ſavorie and ſweet. The Tartarians alſo and nations in Sarmatia, feed moſt of this water

gruell made with Millet: as alſo with the crude and raw meale thereof unſodden and unbaked, tempered with mares milke, or els with horſe-bloud that runneth out of their maſter leg-vaines, by way of inciſion made for the purpoſe with the phleame. As for the Æthiopians, they know no other corne but Millet and Barley. Panicke is eaten in ſome parts of Gaule, and principally in Aquitane or Guien: in Piemont alſo, and all about the Po, it is a great feeding, ſo there bee beanes among; for without beanes they cannot skill how to dreſſe any thing for their daily food. The regions that confine upon the Euxine ſea or Pontus, have no daintier meat than that which is made of Panick. To conclude, all Summer corne abovenamed, delight more to grow in moiſt and watery grounds, than to bee wet with ſhowres and raine from above. And yet I muſt needs ſay, that Millet and Panicke care leaſt for warer or moiſture, when they begin to put forth their blade. Laſt of all, there is no good husbandman but will forbid to ſow Millet and Panicke either in vineyards, or among trees that beare fruit; being perſuaded, that the ſowing thereof doth eat out the heart of the ground.

Chap. xi.

Of Levains: the manner of making bread: ſundrie kinds of bread: about what time Bakers were firſt knowne at Rome: of Sieves and Serces, of Raungers and Bulters. Laſt of all, of the Frumentie called Alica.

THe meale of Millet is ſingular good for Levaines, if it be wrought and incorporate in new wine, for ſo it may be kept a whole yeare. The like is made of the better brans of wheat, ſo they be ſmall, fat, and not too near raunged; and the ſame be kneaded in new white wine of three daies old, and then dried in the ſunne. Hereof is made a dough or paſt, and the ſame is reduced into certaine round cakes or Troſches to ſerve for the making of bread; for theſe muſt be ſoked and diſſolved in hote water with the floure of the corne Zea, and therein be ſodden: which done, they uſe to mingle it with the meale and floure to make paſt of, which they hold to be the beſt way of making bread. The Greeks have ſet downe this proportion, allowing to every peck or Modius of meale, eight ounces of levain; and this they thinke to be ſufficient. Now theſe kinds of levains verily cannot be made, but only in time of vintage. But if a man would make levains at any other time, he may take of barly meale tempered with water ſo much as it may be brought into a paſt; and when there be certain lumps or cakes hereof made, weighing two pound apeece, they muſt be baked either upon the hearth under hot embres, or els in an earthen pan over the coles, untill ſuch time as they looke browne and red withall. Afterwards they be put up cloſe covered in pots or ſuch like veſſels, and there remain untill they wax ſower. Now when a man would uſe levain, hereof he taketh what he will, and diſſolveth it as is before ſaid. In old time when they made barley bread, they uſed no other levaine for it but only the meale of Ervile or Cich peaſe; and ordinarie it was, to take two pound thereof for * two pecks and an halfe of meale: but now adaies the order of our huswives is, to make levains of the very ſame meale which is kneaded and wrought into dough, before ſalt be put thereto, which they ſeeth to the conſiſtence of a pulpe or thicke batter, and ſo let it lie untill it become ſowre. And yet commonly they doe not boile their levains, but only reſerve ſome of the paſt or dough, whereof they make their bread the day before. As touching the nature of Levain, certein it is that it proceeded of ſoureneſſe; like as it is generally held, that they be ſtronger of bodie who feed of levained bread: for in old time it was verily thought, that of the weightieſt and heavieſt kind of wheat, there was made the holeſomeſt bread.

* *quinque ſemodios.*

Concerning the ſundrie ſorts of bread that is made, it ſeemeth a needleſſe peece of worke to ſet them downe every one in particular: for ſometimes bread taketh the name of the meats and viands that be eaten therwith: as for example, Oiſter-bread, ſo called for that it was good with oiſters: otherwhiles it beareth the name of ſome daintie cates, as Artolaganus, [*i.* pancake, fritter, or fine cake-bread.] As for the bread called Speuſticus, [*i.* Haſtie] it is ſo called, becauſe it was made in haſt. The manner alſo of the baking, giveth denomination to ſome bread; as to Furnaceus panis, which was made in a furnace; to Artoptitius, made in a baking-pan called Artopta: as alſo to that which was baked in an oven. Not long ſince alſo there was a new device of making bread brought out of Parthia, which becauſe the paſt is drawne through water (and yet a ſpungious, light, and hollow ſubſtance it carrieth) they call water bread; and ſome give it the denomination

A nation of Parthicke bread. But howſoever it be, the beſt bread is of the fineſt wheat floure, which hath paſſed through a ſmall tamis bulter. Some countries there be, that knead their dough with milke or egs; others alſo put butter thereto: but thoſe bee ſuch nations as are not troubled with wars, ſince that they can have while to ſet their minds on ſundrie ſorts of paſtrie. The Picenes in times paſt invented a way by themſelves of making bread, with the very matter or ſubſtance of the frumentie Alica; and ſurely that deviſe holdeth ſtill and is much uſed. The manner thereof is this: They take the ſaid frumentie paſt and ſteepe it in water nine daies; on the tenth day they worke or knead it with the juice of Raiſons, to the faſhion of a Parthicke cake driven thin and broad; after this they put it in earthen pots, ſet them in ovens for to frie and bake, that the ſaid pots may there breake in ſunder: and being thus hard baked, it is not to be eaten unleſſe it be ſo-
B ked in ſome liquor, which ordinarily is milke, or mead eſpecially.

There were no Bakers knowne at Rome for the ſace of 580 yeares after the foundation of the citie, untill the Perſian warre. Before that time every Romane citizen had his owne bread baked at home; and womens worke commonly it was, like as at this day it is in moſt countries: for this appeareth by *Plautus*, who in his Comœdie entituled Aulularia, maketh mention of *Artopta; a baking-pan [which men have uſually in their houſes:] and hereupon is growne much diſpute and controverſie betweene learned men about this Queſtion, Whether that verſe were of that Poets making or no? for certein it is (according to the opinion of *A. Atteius Capito*) that at ſuch mens bourds as kept great houſes and delicate fare, there was no other bread eaten but ſuch as Cookes were wont to make them, after the manner of ſimnels: for Piſtores were thoſe only then
C called, who husked and cleanſed the bearded red wheat named in Latine Far; and other Bakers than they, were there none. Neither had the Romane citizens in ordinarie, any Cookes as their houſhold ſervants, but hired them out of the market whenſoever they had any meat to dreſſe.

* *Ego hanc Artoptam ex proximo utendam puto.*

Divers ſorts of ſieves and bulters there be. The Sarce made of horſe haire, was a deviſe of the Frenchmen: the tamis raunger for courſe bread, as alſo the fine floure bulter for manchet, (made both of linnen cloth) the Spaniards invented. In Ægypt they made them of papyr reed and ruſhes. But now that wee are entred ſo far into this matter as touching corne, I thinke it not amiſſe before I proceed any farther, to ſpeak (with the firſt) of the frumentie called Alica, and the manner thereof, being (as it is) ſo excellent and holeſome to be eaten; and which, no doubt, tho-
D roughout all Italy, beareth the name for the very beſt of all corne whatſoever. No queſtion, but there is made thereof in Ægypt; howbeit nothing to the other. In Italy, many places there bee where it is to be had, as namely in the territories of Verona and Piſæ: but that of Campaine carieth the price and praiſe above all the reſt: a champion or plaine countrey this is, for the ſpace of fortie miles lying as a vale under the hills and mountaines, ſubject to watery clowds and tempeſtuous winds. The ſoile of this whole tract (to ſpeake directly of the nature thereof and defer no longer) is light and duſtie, if a man reſpect the upper coat thereof, but underneath it drinketh in much moiſture, whereunto apt it is by reaſon of certain fiſtulous poroſities therein, like a pumiſh ſtone: in which regard, the mountains commaunding theſe plaines (ill neighbours otherwhiles) doe it much good and mend the ſoile very well; for many a ſound ſhowre (which ordinarie falleth from the hills) paſſeth and runneth through it, as it were a colander; by means where-
E of, the ground ſtandeth not drenched and ſoked with water, but is thereby more pliable & eaſie to be tilled. Now this ſoile having thus received ſtore of water, doth not yeeld it up againe boiling out at any ſprings, but keepeth and cheriſheth it ſtill within, as it were the radicall and nutritive humour, concocting the ſame to a very good temperature. All the yeere long a man ſhall ſee it ſown and ſtanding with corn, one or other; for the ſame ground beareth one crop of Panick, and two of the red wheat Far: it never reſteth but beareth ſomewhat: for ſay that ſome lands lye fallow between-while, and are not ſowed with corne; they yeeld roſes in the ſpring of themſelves naturally, and thoſe far ſweeter than the garden roſes: ſo fruitfull is it and cannot abide to be idle and do nothing. Hereupon aroſe the proverb of this land of Campaine, *That greater ſtore is there to be found of ſweet perfumes and odoriferous ointments, than of ſimple oyle in other countries whatſoe-*
F *ver.* And looke how much this tract of Campain ſurpaſſeth all other lands in goodneſſe and fertilitie, ſo much excelleth one quarter thereof (called in Latine Laboriæ, and by the Greeks Phlegræum) all the reſt, and goeth beyond it ſelfe. This plaine aforeſaid named Laboriæ, is confined on both ſides with the great cauſies or high waies raiſed by the Conſuls, and thereupon called Conſulares; the one goeth from Puteoli, the other from Cumes, and lead both to Capua.

But to come againe unto our Frumentie Alica, made it is of the graine Zea, which before wee tearmed by the generall name of Seed. This corne for to make Frumentie, is to bee pound in a wodden morter, when it ſhould be cleanſed from the huske: for if a man beat it in one of ſtone, the hardneſſe thereof would bruſe and breake it. The beſt way of cleanſing and husking it, is with a peſtill, ſuch as bondſlaves and priſoners do uſe to ſtampe withall, and to worke by taske for their puniſhment: in the forepart thereof it hath a circle of yron, made in faſhion of a round Boxe: wherewith after the corne is drawne naked out of the huske, the very ſame inſtrument ſerveth againe to ſtampe and bruſe the white marrow and flower thereof within. And thus by this meanes there be three ſorts made of Alica or Frumentie aforeſaid. The fineſt, which is the beſt: the meane, which is the ſecond: and the greateſt or groſſeſt, which the Greekes call Aphærema. G

When all this is done, yet have they not that whiteneſſe of their owne, for which they are ſo much eſteemed; as namely, thoſe that come now adaies from Alexandria, which are taken to be the beſt and to excell all other. And therefore there is chalke (a wonderfull thing to be ſpoken) mingled afterwards and incorporate therewith, and ſo by that meanes the Frumentie becommeth white and tender withall. Now this chalke or plaſtre is found between Puteoli and Naples, in a little hill which thereupon is called Leuco-gæon, [*i.* white earth.] And in truth when *Auguſtus Cæſar*, late Emperor of Rome, erected a colonie at Capua, and peopled it with Romane cittizens, he aſſigned unto the Neapolitanes (by vertue of a decree, now extant) an yearly rent or penſion of twentie thouſand deniers to bee paied out of his owne treaſure, in regard of the chalke which came from the hill aforeſaid, being within their territorie and ſiegnorie. He rendereth alſo a reaſon inducing him thus to doe, Becauſe the inhabitants of Capua, alleadged, that they could not make good Alica or Frumentie without that minerall of chalke. In the ſame hill there is alſo found a Brimſtone mine, and out of the veines thereof, fountaines ſpringing, called Oraxi, the water whereof is ſingular good to cleare the eies, to cure and heale greene wounds, and to faſten the teeth that are looſe in ones head. H

As touching a baſtard kind of Frumentie, it is made verily for the moſt part of a Spelt or Zea in Affricke, which there doth degenerate & grow out of kind. The eares that it carieth, are broader and blacker than the other, and the ſtraw is but ſhort. They uſe to cleanſe and huske it by ſtamping or braying it together with ſand: and for all that deviſe, much adoe they have to fetch off the huls and huskes wherein the graine lieth encloſed: now when it is thus cleanſed and naked, it is not paſt halfe as much in meaſure as it was before. Which done, there is a fourth part of plaſtre ſtrewed and mingled among: and when all is together, they ſift it downe through a meale ſieve. That which remaineth behind and paſſeth not through, is the groſſeſt part thereof, and is called in Latin Exceptitia. That which was thus ſearced, is driven again through a narrower and finer ſieve, and theſe groats that tarie in the raunger, they call Secundaria. In like manner do they a third time, ſearcing it through ſo fine a ſieve, that nothing can paſſe but the very ſmall ſand and pouder: and this laſt kind of Frumentie gurts they name Cribraria. Another way there is beſides in all places practiſed, to ſophiſticate and counterfeit the right Frumentie groats indeed: They chuſe out of our common Wheat, the faireſt, fulleſt, and whiteſt graines, which being halfe ſodden in an earthen pot, they lay out afterwards in the Sunne, untill they be as drie as they were at firſt: which done, they lightly ſprinckle ſome water over, and then bruſe them in a quearne mill. Fairer Frumentie groats be made of Zea than of Wheat, and called it is Granum or Granatum, although in Alica that be counted a fault. To conclude, they that will not uſe chalke, doe blaunch and make their Frumentie white by ſeething milke with it, and mingling all together. I K

Chap. xii.

& of Pulſe.

IT followeth now to write of the nature of Pulſe, among which, Beanes doe challenge the firſt ranke and principall place: for thereof men have aſſaied to make bread. The meale of Beanes is called in Latine Lomentum. There is a not a Pulſe weigheth more than it, and Beane meale maketh every thing heavier wherein it is. Now adaies they uſe to ſell it for provender to feed horſes. And indeed Beanes are dreſſed and uſed many waies, not onely to ſerve all kind of foure-footed beaſts, but alſo for man eſpecially. For in moſt countries it is mingled with Frumentie corne: and namely with Panicke moſt of all, whole and entier as it is: but the more delicate and M

daintie

A daintie way is to breake and bruiſe it firſt. Moreover, by auncient rites and rellgious ceremonies; at the ſolemne ſacrifice called Fabaria, the manner was to offer unto certain gods and goddeſſes Beane cakes. This was taken for a ſtrong food, being eaten with a thicke grewell or pottage; howbeit, men thought that it dulled a mans ſences and underſtanding, yea, and cauſed troubleſome dreames in the night. In regard of which inconveniences, *Pythagoras* expreſſely forbad to eat Beanes: but as ſome have thought and taught, it was becauſe folke imagined, that the ſoules of ſuch as were departed, had reſidence therein: which is the reaſon alſo, that they be ordinarily uſed and eaten at the funerals and obſequies of the dead. *Varro* alſo affirmeth, That the great Prieſt or Sacrificer called the Flamine, abſtaineth from Beanes both in thoſe reſpects aforeſaid, as alſo for that there are to be ſeene in the flower thereof certaine letters or characters that ſhew heavi-
B neſſe and ſignes of death. Furthermore, there was obſerved in old time a religious ceremonie in Beanes: for when they had ſowed their grounds, their manner was, of all other corne to bring backe with them out of the field ſome Beanes, for good lucke ſake; preſaging thereby, that their corne would returne home againe unto them; and theſe Beanes thereupon were called in Latine Refrivæ, or Referivæ. Likewiſe in all port-ſales it was thought, that if Beanes were entermingled with the goods offered to be ſold, they would be luckie and gainefull to the ſeller. This is certain, that of all fruits of the earth, this onely will bee full and ſound when the Moone is croiſant, notwithſtanding it were gnawne and halfe eaten with ſome thing before. Set them over the fire in a pan with ſea water or any other that is ſaltiſh, they will never be throughly ſodden. They are ſet or ſowne before the retrait of the Starre Vergiliæ, [*i.* the Brood-hen] the firſt of all other Pulſe,
C becauſe they might take root betimes & prevent the Winter. And yet **Virgill* would have them to bee put into the ground in the Spring: like as the manner is in Piemont and Lumbardie, all about the river Po.

**Vere fabis ſatio. Georg. lib. 1.*

But the greater part of good Husbandmen are of this opinion, That the ſtalke or ſtraw of Beanes ſowne earely or ſet betimes, are better than the very fruit it ſelfe, which hath had but three moneths being in the ground. For the cods and ſtalkes onely of Beanes are paſſing good fodder and forrage for cattell. Beanes when they are blouming, and in their flower, deſire moſt of all to be refreſhed with good ſtore of raine: but after they have done flouring, they care for little. The ſowing of this Pulſe in any ground, is as good as a mucking unto it, for it enricheth it mightily. And therefore towards Macedonie and about Theſſalie, the manner is when Beanes begin to
D bloſſome, for to turne them into the ground with the plough. Beanes come up and grow in moſt places, of their own accord without ſowing; and namely, in certain Iſlands lying within the Northerne Ocean, which our countreymen thereupon have named Fabariæ. Semblably, they grow wild commonly throughout all Mauritania, but exceeding hard and tough they bee, and ſuch as poſſibly cannot be ſodden tender. There are likewiſe in Ægypt to be found Beanes, with a ſtalke beſet full of prickes or thornes: which is the cauſe that Crocodiles will not come neare them, for feare of hurting their eyes. The ſtemme of theſe Beanes is foure cubites in height, but exceeding thicke and big withall: tender it is notwithſtanding, and ſoft, running up even and ſmooth without any knots or joints at all: it carieth a head in the top like Chesboule or Poppie, of a roſe red colour: wherein are contained not above 30 Beanes at the moſt. The leaves be large: the fruit
E it ſelfe (or the Bean) is bitter in taſt, and the ſmell not pleaſant: howbeit the root is a moſt daintie meat, which the inhabitants doe eat as well raw as ſodden; and like it is to reed and cane roots. Theſe grow in Syria and Cilicia, as alſo about the lake Torone, within Chalcis.

Much like to the proverbe here in England, *March Ote-ſtraw is better than Aprill Otes.*

As touching other Pulſe, Lentils be ſowed in November, and ſo are Peaſe, but in Greece only. Lentils love a light ground better than a fat and heavie: they like alſo drie and faire weather. Two kinds thereof bee found in Ægypt: the one more round and blacke than the other; the reſt bee faſhioned as common Lentils. According to the manifold uſe and diverſe effects of Lentils, there have ſundrie names and denominations been borrowed from them: for I find in writers, that the eating of Lentils maketh men to bee mild and patient, whereupon they bee called Lenti and Lenes. As for Peaſe, it ought to be ſowed in warme places lying well upon the Sunne,
F for of all things it cannot abide the cold. Which is the cauſe, that in Italie and in other countries where the clime is rough and hard, they are not ſowne uſually but in the Spring, and folke chuſe a gentle, light, and looſe ground.

To come now to the Cich peaſe, the nature of it is to be nitrous and ſaltiſh, and therefore it burneth the ground where it groweth. Neither muſt it be ſowne, unleſſe it were well ſteeped and

ſoked in water the day before. Many ſorts there be of theſe Cich peaſe, different in bignes, form, colour, and taſt: for there are both blacke and white, and thoſe in faſhion ſhaped like to a Rams head, and thereupon they are ſo called. There is a ſecond kind named Columbinum, or by others Venerium. Theſe are white, round, light, leſſe than the former Rams-head Ciches, which men do eat ceremoniouſly with great religion, when they meane to watch throughly all night long. There is a little Cich peaſe alſo, called Cicercula, made cornered and otherwiſe uneven, like unto a Peaſe. But the beſt Ciches and moſt pleaſant are thoſe that come neareſt in reſemblance to the Ervile: and generally the red kind and the black are more firme and faſt than the white. Cich peaſe grow within round cods, whereas other Pulſe be contained in long and flat, according to the forme and figure of the ſeed which they hold: Peaſe by themſelves have a long round cod in forme of a Cylinder.

The Pulſe called Phaſeoli, [*i.* Kidney Beanes] uſe to be eaten cod and all together. Theſe may be ſet or ſowne in what ground you liſt, from the Ides of October to the Calends of November. Finally, all kinds of Pulſe, ſo ſoone as they begin to ripen, are to be gathered or plucked haſtily: for ſtay never ſo little, they leape out of their cods and ſhed, and being once fallen, they lie hidden in the ground; like as the Lupine alſo.

Chap. XIII.

Of Rapes or Navewes: of Amiternium Turneps.

NOw let us proceed and paſſe to other matters: & yet in this diſcourſe, it were meet to write ſomewhat as touching Rapes or Navewes. The Latine writers, our countreymen, have ſlightly paſſed by and touched them onely by the way. The Greekes have treated of them ſomewhat more diligently, and yet among pot herbs and woorts growing in gardens; whereas indeed according to good order they would be ſpoken off immediatly after Corne, or Beanes at leaſt wiſe, conſidering there is not a plant of more or better uſe than is the Rape or Navew. Firſt and formoſt, they grow not onely for beaſts of the earth and the Foules of the aire, but alſo for men. For all kinds of Pullen about a Farme-houſe in the countrey, doe feed upon the ſeed thereof as much as of any thing elſe, eſpecially if they bee boiled firſt in water. As for foure-footed beaſts, they eat the leaves thereof with great delight, and waxe fat therewith. Laſt of all, men alſo take as great pleaſure and delight in eating the leaves and heads of Rapes or Navewes in their ſeaſon, as they doe of young Coly-Flories, Cabbages, or any tender crops of hearbes whatſoever; yea, when they are faded, flaggie, and dead in the Barne, they are eſteemed better, than being freſh and greene. As for Rapes or Navewes, they will keepe long and laſt all Winter, both within the ground where they grew: and beeing well wintered, they will continue afterwards out of the earth lying abroad even almoſt till new come: ſo as they yeeld men great comfort to withſtand all hunger and famine. In Piemont, Lumbardie, & thoſe countries beyond the Po, the people make the moſt account of gaine by gathering Rapes, next to wine vintage and corne harveſt. It is not choiſe and daintie, of the ground where it will grow: for lightly it will proſper where nothing els can be ſowed. In foggie miſts, hard froſts, and other cold weather, it thriveth paſſing wel, & groweth to a wonderfull bigneſſe. I have ſeene one of their roots weigh above fortie pounds. As touching the handling and dreſſing of them for our table, there be many waies and deviſes to commend and ſet them out. Preſerved they may be untill new come, eſpecially condite with ſharp and biting Senvie or Muſtard ſeed. Moreover, our Cookes know how to give them ſix other colours beſides their owne which is pure and naturall; they have the caſt to ſet even a purple hew upon them. And to ſay a truth, there is no kind of viands beſides that, being thus painted & coloured, hath the like grace. The Greeke writers have devided them by the ſexe, and thereby made two principall kinds thereof, to wit, the male and the female. Nay, more than that, out of one and the ſame ſeed, according as it is ſowed, they can make male or female, whether they pleaſe. For if they ſow thicke, and chuſe thereto a hard and churliſh ground, it will prove of the male kind. Alſo, the ſmaller that the ſeed is, the better is it eſteemed. But of all Rapes male or female, three eſpeciall ſorts there be and no more. For ſome roots ſpread flat and broad, others are knit round like a ball; the third ſort which runneth downe into the ground with a long root in manner of a Raddiſh, they call the wild Rape or Navew: this beareth a rough leafe and full of angles or corners; the juice that it yeeldeth is ſharpe, hote, and biting, which being gathered in harveſt time & reſerved,

mundi-

A mundifieth the eies, and cleareth the ſight, eſpecially being tempered with breaſt-milke. If the weather be cold, they are thought not onely to thrive in bigneſſe of the root, but alſo to proove the ſweeter, whereas contrariwiſe in a warme ſeaſon they run up all to ſtalke and leaſe. The beſt ſimply are thoſe that grow in the Nurſine territorie. For they are ſold by the weight: and everie pound is worth a Romane Seſterce, yea, and otherwhiles twaine, if there be any ſcarcitie of them. Next to theſe in goodnes be thoſe that come out of Algidum. Thus much of Rapes or Navews.

As for the Turneps of Amiternum, they bee in a manner of the ſame nature that the Rapes aforeſaid, and cold they love as well. Sowne they are before the Calends of March: & four quarts of their ſeed will take up a whole acre of ground. The beſt Husbandmen, and ſuch as are more exquiſite in their practiſe of Agriculture, give order, That the ground for Turneps ſhould have
B five tilthes, whereas Rapes or Navewes are content with foure: but both the one & the other had need of a ſoile well enriched with dung or compoſt. By their ſayings alſo, Rapes will proſper the better and come up thicker, if they be ſowed in their huls, chaffe and all together. Moreover, they would have the ſeeds-man to be naked when he ſoweth them, and in ſowing to proteſt, That this which he doth is for himſelfe and his neighbours, and withal to pray as he goeth. The proper ſeaſon for the ſeednes of them both, is betweene the feaſts of the two gods, to wit, *Neptune* and *Vulcane*.

To conclude, there is a ſubtile and curious obſervation that many go by and doe hold, namely this, To marke how many daies old the Moone was, when the firſt Snow fell the Winter next before: for if a man doe ſow Rapes or Turneps, within the foreſaid compaſſe of that time, the
C Moone being ſo many daies old, they will come to be wonderous great, and encreaſe exceedingly. Men uſe to ſow them alſo in the Spring: but then they make choiſe of moiſt and hote grounds.

Chap. xiiii.

Of Lupines.

After Rapes and Turneps, the Lupines have greateſt uſe, and deſerve to be raunged next: for that they indifferently ſerve both men and alſo all foure footed beaſts that be houſed, either whole or cloven. Now for that the ſtalke is very ſhittle in mowing, and therefore flyeth from the edge of the ſyth, the onely remedie therefore (that the mower may catch it) is
D to go to worke preſently after a good ſhowre. And verily there is not a plant growing upon the earth (I meane of ſuch as are ſowne of ſeed) more admirable than the Lupine, in regard of the great amitie and ſympathie betweene the earth and it. Looke how the ſunne keepeth his courſe in our Horizon above, ſo doth it turne and goe withall; in ſo much as the husbandmen of the countrey go by no other clocke to know how the day paſſeth, in cloſe and clowdie weather, than this obſervation. Moreover, it hath three ſeaſons of blowming: it loveth the earth well, but yet willingly it would not be covered over with mould: for this is the onely ſeed that is ſowne upon ground without any ploughing or digging: it would grow to chuſe, in a moſt gravelly, drie, and ſandie ſoile; and in no caſe can it abide any tending or husbandrie about it: ſo affected is it to the earth, that caſt it upon any rough ground, among buſhes, leaves, briers and brambles, it will chit
E and ſpurt nevertheleſſe, and never lin till it take root within the earth. If Lupines be ſowed either in vineyards or upon corne lands, they enrich the ſame and make the ground better, as we have before written: and ſo little need have they of dung, that they ſtand in ſtead of the very beſt. To ſay a truth, there is no graine leſſe chargeable to bee ſowne, than it; nay there is none coſteth nought at all, but it; for it needeth not ſo much as to be brought into the field: and why? it ſoweth it ſelfe preſently in the ſame field where it grew: and ſhedding as it doth of the owne accord, a man never needs to caſt and throw it upon the land, as other corne. It is firſt ſowne, and laſt gathered: and lightly both theſe ſeaſons fall out in the moneth of September; for if the Seednes prevent not the winter, ſo as it may have good root before it commeth, it will bee in daunger of the cold. Over and beſides, if it chaunce to lie bare and uncovered above-ground, leſt
F careleſſely without any keeping, and that no rain come upon it preſently for to drive it into the ground, it is ſafe enough and catcheth no harme; for ſo bitter it is, that no living creature will touch it: and yet for the moſt part the husbandmen beſtow a light furrow upon it, and ſo cover it very ſhallow. If the ground be faſt and heavie, it loveth that beſt which ſtandeth upon a red clay. And for the maintaining and enriching of this kind of ſoile, it muſt be turned up or eared after

after the third flouring: but in caſe it be gravelly or ſandie, it will ſerve to doe it after the ſecond. Chalkie grounds onely and myrie it hateth, and therein it will not grow. As bitter as otherwiſe it is, yet if it be ſteeped and ſoked in hote water, it is mans meat alſo. Moreover, one Modius or pecke of Lupines is ſufficient for to ſatisfie and feed an oxe or a cow at a time: and this kind of provender will make beaſts ſtrong and healthfull. Moreover, the meale of Lupines applied to the bellies of young children that have the wormes, is a ſingular remedie. For the good keeping of Lupines, all men agree that they ſhould bee laid up in ſome chimney or ſmokie place eſpecially; for if they lie in a moiſt roome, there be certaine little worms that will nibble off and eat the tip or navell that it hath, and by that meanes marre it for ever ſprouting againe. Finally, if Lupines be eaten downe by beaſts, while they be greene in the leafe, the ground where they grew muſt preſently be ploughed up.

Chap. xv.

Of Vetches and Ervile.

VEtches alſo doe manure and fat the ground where they be ſowed; neither be they chargeable or ſtand the husbandman in much: they be ſown with one tilth; otherwiſe there needs no harrowing nor weeding: there is required no mucking; only they would be covered with mould and the clods broken. For ſowing of Vetches, there be three ſundrie times: firſt, about the ſetting of the ſtarre Arcturus, that by the moneth of December it may get a good head for to be eaten with beaſts; and it is generally holden, that beeing ſowed in this ſeaſon, it will bring the beſt ſeed; for ſay it be eaten downe then, it will carrie the burden nevertheleſſe: the ſecond Seednes is in Ianuarie: the laſt in March; and beeing then put into the ground, it will run up moſt to blade, and yeeld the beſt forage for cattell. Of all ſeeds that are caſt into the earth, it loveth drought moſt: it can brooke alſo ſhadie places well enough. The chaffe that commeth of the ſeed thereof, is excellent good; and better than any other, in caſe it were ripe when it was gathered. It robbeth vines of their nouriſhment, if it bee ſowed neare thoſe trees whereto vines are wedded; inſomuch as a man may ſee evidently how they languiſh.

As touching Ervile, it asketh no great hand or travaile about it: yet thus much more attendance it requireth than Vetches, for that it muſt be weeded and grubbed about the roots. Beſides, this kind of pulſe is of great uſe in Phyſicke; for *Auguſtus Cæſar* was cured of a diſeaſe that he had, and recovered his health by the meanes of Ervile, as himſelfe reporteth in ſome of his letters now extant. Moreover, five Modij or pecks of Ervile ſowne, is ſufficient to maintain and find a yoke of oxen. As for that which is ſowne in March, it is hurtfull forage (men ſay) for kine and oxen: as alſo that which they ſow in Autumne, maketh beaſts heavie and ſtuffed in the head: but that which is put into the ground in the beginning of the Spring, is harmeleſſe.

Chap. xvi.

Of Fœnigreeke: of Rie: of Dredge: of the provender corne or Bolimong Ocymum: of Spaniſh Trefoile or horned Claver-graſſe, called in Latine Medica: of the ſhrub Trifoile, named Cytiſus.

FOr the ſowing of Silicia or Siliqua, otherwiſe called Fœnigreeke, there needs no more but to ſcarrifie or ſcrape it lightly up with a furrow not above foure fingers breadth deepe; for the leſſe coſt and husbandrie that is beſtowed about it, and the woſſe that it is uſed, the better it proſpereth and yeeldeth greater encreaſe: a ſtraunge thing to be ſpoken and ſeldome verified, *That Negligence ſhould be any waies profitable*; and yet herein it prooveth true. That which is called * Secale and Farrago in Latine, [*i.* Rie] needeth no more adoe but to be harrowed and the clods well broken. There is a kind of Secale or Rie, which the people called Taurines dwelling under the Alpes, doe call Aſia: it is ſimply worſt of all other, and good for nothing but onely to drive away hunger: plentifull enough this corne is and yeeldeth good encreaſe, but the ſtraw is ſlender: blacke it is and of an unpleaſant colour, howbeit exceeding weightie and ponderous: they uſe to mingle the red wheat Far therewith, and make thereof a Maſcelline, to allay the bitterneſſe thereof; and yet for all that, the bread which it maketh is moſt unſavorie to the mouth and ill for the ſtomack. It will come up in any ground whatſoever, and bring forth a hundred fold

ordina-

A ordinarily; neither doth it eat the ground out of heart, but rather maketh it more battle, and ſerveth in ſtead of compoſt or mucke.

As for that kind of dredge or farrage which commeth of the refuſe and light corne purged from the red wheat Far, it ought to be ſowne very thicke, with Vetches otherwhiles mingled among. In Africke, the ſame mixture is made of Barley. All theſe are good onely for provender and beaſts forage: as alſo a baſtard kind of Vetches called * Cracca, which pigeons love ſo well, that if they be fed once therewith, they will never leave the place where they taſted it, nor flie far from thence. In time paſt our aunceſtours had a kind of fodder or provender, which *Cato* called Ocymum, wherewith they * uſed to ſtay the gurrie in kine and oxen. This forrage was made of * beane ſtalkes cut downe greene as it ſtood before it was joynted and codded. But *Sura Manlius* B taketh this dredge to be another thing, ſaying, That in old time they uſed to put unto ten Modij of Beanes, twaine of Vetches and as many of Ervile, and ſo were woont to blend all togither and ſow them in an acre of ground at the fall of the leafe: and (ſaith hee) it would be the better balimong if there were ſome Greeke Otes mingled withall, ſuch as never ſhed the ſeed out of the haw. This manner of dredge was called uſually Ocymum, and was woont to be ſowne for a kind of forrage to ſerve kine and oxen. *Varro* ſaith, that it tooke that name becauſe it commeth up ſo ſpeedily, as being derived from the Greeke word ὠκὺς, which ſignifieth, Quicke, or Swift.

As for the graſſe or hearb Medica [a kind of Claver or Trefolie] the Greekes held it in old time for a meere ſtraunger, as being brought into Greece from Media during the Perſian wars, which King *Darius* levied againſt Greece: howbeit, an excellent Simple it is, and worthy to be C written of in the firſt place. And to begin withall, this ſingular propertie it hath, That with once ſowing, it continueth above thirtie yeeres without any need of renewing. Like it is to Claver or three-leaved graſſe, both in leafe and ſtalke, but that the ſtemme is parted by knots and joints. Moreover, as it riſeth higher and runneth up in the ſtalke, the leaves grow narrower. Of this herb alone and of Cytiſus, *Amphilochus* compiled one whole booke; howbeit, he wrate of them both confuſedly. The ground wherein it is to bee ſowed, after it is well rid of ſtones and cleanſed, muſt be broken up and well tilled in the fall of the leafe. Soone after it needeth to have another fallow and be harrowed withall, and then covered with hardles: this would bee done two or three times (five daies betweene) and therewith it ought to bee throughly dunged. This hearbe requireth a ſound drie ground, and yet ſuch as is full of ſucculent moiſture within, or elſe where water is neare D at hand to commaund. The ground beeing thus prepared, ought to bee ſowed in the moneth of May following, for otherwiſe the froſt would take it and marre all. Moreover, requiſite it is, that it be ſowed very thicke, ſo as every place be taken up therwith, thereby to exclude all other weeds and give them no roume there to grow. To this effect therefore every acre will take twentie Modij or pecks of ſeed. But take heed withall, that it be not burnt ſo ſoon as it is put into the ground, and therefore immediately it muſt be covered with mould. If the ſoile be moiſt and given to bear other graſſe, the ſeed is ſoone overgrowne and choked, and then all will run to graſſe, and turne to be a meddow. Which graſſe or coich when you ſee begin to overrun the ground, it muſt be all weeded out preſently an inch deepe within the ground, and by hand rather than any weeding hooke or thiſtle-ſpade. Now, when this hearbe Medica or Claver graſſe beginneth once to flour, E cut it downe: and ſo often as it floureth againe, downe with it. Thus you may have ſixe mathes in one yeare, or foure at the leaſt. You muſt never let it ſpindle and beare ſeed: for better is it to take it thus in the growth, while it is but young and greene graſſe, for three yeares together: and the forrage or fodder is moſt profitable. Sowne (I ſay) it muſt bee in the Spring, and weeded for the firſt three yeares. The greene ſourd afterwards ought to bee pared away with hookes and ſpades cloſe to the ground: for by this meanes you ſhall bee ſure, that all other weeds will die, and this hearbe take no harme by it, for that by this time it is deepely rooted. If the weeds doe get head and overcome it, the onely remedie is by the plough, to turne up the ground over and over ſo many times, untill all other roots be killed. Moreover, heed muſt bee taken, that of this herbage or fodder, beaſts doe not eat their fill; for feare you be driven of neceſſitie to let them bloud, and F take downe their rankeneſſe. The greener that it is, the more profite commeth thereof: for it drieth braunch after braunch, untill at length it will crumble like duſt or pouder, and then is it good for nothing.

As touching Cytiſus, [*i.* the Shrub Trifolium] which is a ſingular kind of paſturage, and paſſeth all the reſt, I have written at full in my diſcourſe of Shrubs. For now at this preſent I am to proſecute

* or, rather *Arachos.*

* *Siſtebant. Varro* ſaith *Citabant*, which is clean contrary.

* *Sabali ſegete antequã generet.*

cute and goe through the treatiſe of other ſorts of corne and their nature, if I had once written ſomewhat in one part thereof as touching the accidents and imperfections that happen among them. G

Chap. xvii.

The faults incident to corne, and their remedies. Alſo what corne is reſpective to this or that ſoile, for to be ſowne therein.

THe firſt and principall defect obſerved in bread-corne, and Wheat eſpecially, is when it doth degenerate and turne into Otes: and not onely it, but Barley alſo doth the like. Semblably, Otes otherwhiles ſerve the turne in ſteed of bread corne: as wee may ſee in ſome countries of Almaine, where they do uſually ſow it, and commonly they have no other pottage there, than Oatmeale gruell [which they call Abremouz.] The foreſaid defect and imperfection is occaſioned cheefely by the moiſt ſoile or overwet weather. Another cauſe there followeth alſo thereupon, proceeding from the feebleneſſe and weakeneſſe of the ſeed, namely, when it lieth long ſobbing in the ground, before it come up: and hereto may be referred the faultines of the ſeed otherwiſe, namely, if it were worme-eaten or otherwiſe rotten at the time of ſowing. And verily, no ſooner appeareth it above ground, but the foreſaid change or baſtardie may be ſeene, whereby it doth appeare, that the cauſe is in the root. H

A ſecond defect or imperfection there is alſo incident to corne, which hath ſome near reſemblance to the Otes aforeſaid; namely, when the graine being formed and newly come to the juſt proportion of bigneſſe (howbeit, not yet full and ripe) before that it is firme and hard, is ſmitten with a noiſome blaſt, and ſo, like an abortive fruit, decaieth and windereth away within the eare; in ſuch ſort, as there is no ſubſtance left therein, but appeareth void and emptie. Now theſe adverſe and malignant winds hurt all ſpiked corne, as well Wheat as Barley, at three ſeverall times: to wit, in their flower; preſently upon their blouming; and laſt of all, when they begin to ripen; for then, namely when they are upon the point of maturitie, thoſe blaſts conſume the graine, and bring it to nothing, which before was full: whereas at the two former ſeaſons they hinder it altogether from knitting and growing. The hote gleames moreover of the Sunne, betweene often clouding, doe much harme to corne. I

Furthermore, there be certaine little wormes breeding in the root, that doe eat it: which happeneth by occaſion of much raine falling immediately after the ſeednes, eſpecially, when ſome ſome ſuddaine heat and drowth enſueth therupon; which bindeth the earth above, and ſo, encloſeth the moiſture conceived within, the very cauſe & nourice of putrifaction. Ye ſhall have other ſuch like vermine engender likewiſe in the very graine of the corne, namely, when the eare doth glow within, and is chafed with ſultrie hote raines. Over and beſides, there be certaine [green] flies like ſmall Beetles, called Cantharides, which doe gnaw and eat the corne. But all theſe, and ſuch like wormes or flies die preſently, when the corne (which was their food) is gone. Moreover, Oile, Pitch, and Tarre, all manner of greace alſo, bee contrarie to ſeed-corne eſpecially; and therefore take heed that you ſow none ſuch as hath caught Oile, Pitch, or Greace. As for ſhowers of raine, good they are for corne, ſo long onely as it is in the greene blade: when corne is blouming (be it either Wheat or Barley, or ſuch like) raine is hurtfull. Marie Pulſe takes no harme therby, unleſſe it be the Cich-peaſe. K L

All kinds of Wheat and other bread corne, when they be toward ripeneſſe, catch hurt by ſhowers; but Barley more than any. Beſides all this, there is a certaine white hearbe or weed reſembling Panicke, growing among corne, and overſpreading whole fields: which not onely hindereth corne, but alſo killeth all the cattell that feedeth thereupon. For as touching ray or darnell, burs, thiſtles, and brambles, I may hold and reckon them, not ſo much for faults and imperfections of corne, as rather the plagues and infections proceeding from the very earth. And for blaſting, which commeth of ſome diſtemperature of the aire (a miſcheefe common as well to corne, as vines) it is as hurtfull as any other maladie whatſoever. This unhappie blaſt falleth moſt often in places ſubject to miſts and dewes, and namely, hollow vallies and low grounds lying under the wind: for contrariwiſe, windie quarters, and ſuch as are mounted high, are not ſubject to this inconvenience. Alſo, wee may number among the faults incident to corne, their rankeneſſe; namely, when the blade is ſo overgrowne, and the ſtalke ſo charged and loden with a heavie head that the corne ſtandeth not upright, but is lodged and lieth along. Moreover, when there falleth M

a great

A a great glut of raine,inſomuch as the ground ſtands with water,there befalleth unto all corn and pulſe,yea,and whatſoever is ſowne,a certaine diſeaſe called in Latine Vrica: inſomuch,as the very Cich-peaſe taketh hurt thereby: for by reaſon that the raine waſhed from them that ſalt qualitie which is naturall thereunto, it becommeth ſweeter than it ſhould bee, and looſeth the kind taſt. There is a weed that claſpeth and tieth about Ciches and Ervile, whereby it choketh and killeth them both: and thereupon it is called Orobanctum, *i.* Choke Ervile. After the ſame manner dealeth *Raie or Darnell by Wheat; wild Otes likewiſe,named by ſome Ægilops, with Barley; as alſo the weed Securidaca, *i.* Ax-fitch, which the Greekes alſo(for the reſemblance that it hath to an axe head) call Pelecinon, *with Lentils. Theſe weeds (I ſay) kill corne by winding about it. Another hearb there is,growing neare to the citie Philippi,which killeth Beans: if the ground
B be fat and good,they name the ſaid weed Ateramnon: but if it bee found in a hungrie and leane ſoile,and namely,when being wet, ſome unhappie wind bloweth upon it,they call it Teramnon. As for the graine of Raie or Darnell, it is very ſmall, and lieth encloſed with a ſharpe-pointed huske. The bread which hath any of this ſeed in it,ſoone cauſeth dizzineſſe and ſwimming of the head. And(by report)in Aſia and Greece the maiſters of the common Baines and Stuphs,when they would keepe away the great reſort of multitude thither, have a deviſe to caſt Darnell ſeeds upon burning coales; for this perfume will quickly ſet them farther off. Moreover,if the Winter prove to be wet and wateriſh,yee ſhall have in the Pulſe called Ervile,a little vermine engendred there,called Phalangion,and it is of the kind of theſe Spiders. Likewiſe upon Vetches there will breed naked dew-ſnailes,yea,and otherwhile thoſe little ones with ſhels or houſes on their backs,
C which creeping from the ground,will gnaw & eat them,that it is a wonder to ſee what foule work they will make. Thus much concerning all the maladies and inconveniences(to ſpeake of)incident to corne. It remaineth now to ſpeake of the remedies.

As touching the cure of thoſe harmes that come by hurtfull weeds to the corne in blade,it conſiſteth principally in two things: namely, either in the uſe of the weeding knife or hooke,when they be newly come up; or elſe in ſtrewing aſhes when the corne is a ſowing. But as for thoſe dangers that touch the ſeed or graine in the eare and cod,as alſo that ſettle about the root,they muſt be prevented by good forecaſt,even before it be thrown into the ground. It is generally thought that if ſeed-corne lie ſteeped beforehand in Wine, it will bee better able afterwards to reſiſt all diſeaſes whatſoever. *Virgill* giveth order to infuſe or ſoke the Beanes that muſt be ſowne, in Nitre
D and Oile lees or dregs: and hee aſſureth us,that they will proſper mightily beſides, and become exceeding great. But others are of opinion, That if for 3 daies before they bee caſt into the earth they lie in urine and ſhere water mingled together,they will being thus prepared,come on apace, and thrive paſſing well. It is ſaid moreover, That if Beanes bee thrice raked and rid from weeds, one Modius of them being whole and ſolide,will yeeld a Modius againe after it is husked & broken. As for other ſeed-corne,it will eſcape the danger of the worme,if either it lie before among Cypreſſe leaves bruiſed; or be ſowed in and about the change of the Moone,namely,when ſhe is not to be ſeene above the earth in our hemiſphære. Many there be who practiſe other remedies: and namely for the Millet,they would have a toad to be caried round about the field before that it be harrowed: which done,to bee put cloſe within an earthen pot,and ſo buried in the middeſt
E of the ſaid field: and by this meanes forſooth,neither Sparrows will lie upon the corne, nor any worme hurt it. Marie,in any caſe this ſame toad muſt be digged out of the ground againe before the field bee mowed,elſe will the Millet proove bitter in taſt. The like experiment they ſay is of a Moldwarpes ſhoulder,for if any corne be ſowed or touched therewith before,it will come up the better and bring more encreaſe. *Democritus* had a deviſe by himſelfe for all ſeed & corne whatſoever,namely,to temper & ſoke the ſame corne in the juice of the hearb Houſleeke or Sea-green, growing upon houſes either tiled or ſhindled; which in Greeke is called Aizoon, and in Latine Sedum or Digitellum; for this medicine will ſerve for all maladies. The common practiſe of our Husbandmen is this,In caſe through the overſweet ſap or juice in greene corne,wormes take to the roots: for to ſprinckle them with ſimple oile lees pure and cleane without any ſalt,and afterF wards to rake it in. Alſo,when the corn begins to joint and gather into knots,then to cleanſe the ground,and put off no longer,for feare leaſt the weeds do get head and overgrow. This I am ſure upon mine owne knowledge, that there is an hearbe (but what proper name it hath I wote not) which if it bee enterred in the foure corners of a field that is ſowne with Millet,it will drive away Stares and Sparrowes,which otherwiſe would by whole flights and flockes lie thereupon and doe much

*Æra.4.

*φακὸν, but more truly ἀετὸν, out of *Theophraſtus*. Thus *Plinie* miſtaketh in many places: and for example,immediately in the word *Ateramnos*, which is appropriate to all Pulſe that require much ſeething, or be hard of digeſtion. *Theophraſt. cap.* 13. & 14. *lib.*4. *de Plant.*

much harme: nay I will ſpeake a greater word and which may ſeeme wonderfull, There is not a C
bird of the aire one or other, that dare enter or approach ſuch a field. Field-mice and Rats are
skared away and will not touch corne, which before the ſowing was either beſtrewed with the
aſhes of Weaſils or Cats, or elſe drenched with the liquor and decoction of water wherein they
were boiled: howbeit this inconvenience enſueth hereupon, That bread made of ſuch corn will
have a ſmach, and ſent ſtrongly of ſuch Cats and Weaſils: and therefore it is ſuppoſed a more
expedient and ſafer way to medicine our ſeed-corne with oxe gall, for to preſerve it from the
ſaid Mice and Rats. But what remedie againſt the blaſt and mildew, the greateſt plague that can
befall upon corne? Mary pricke downe certaine Lawrell boughs here and there among the ſtan-
ding corne, all the ſaid miſts and mildews will leave the corne and paſſe to the Bay leaves, and
there ſettle. What ſhall we doe then to corne when it is over-ranke? Eat it me downe with ſheep H
and ſpare not, whiles it is young and in the blade onely, before (I ſay) it be knotted: and never
feare harme by the ſheeps teeth as neare as they go to the ground: for let it be thus eaten many
times, the corne will be the better, yea and the head will take no harme thereby but proove the
fairer. If ſuch ranke corne be once cut downe with the ſyth, and no more, certein it is that the
graine in the eare will bee the longer to ſee to, howbeit void and without any floure within it: for
ſow ſuch ſeed againe, and it will never grow nor come up. And yet about Babylon, the manner is
to mow it twiſe firſt, and the third time to put in ſheepe to it for to eat it downe; otherwiſe the
corne would never ſpindle, but blade ſtill, and run all to leaſe. But being thus cut and cut againe,
* Fœlicitas ſoli. and eaten in the end, yee ſhall have it to encreaſe and multiply fiftie for one, *ſo fertile is the
ſoile: and if the owner be a good husband beſides, and uſe the ground accordingly, hee ſhall I
reape thrice as much, even a hundred and fiftie fold. And what carefull diligence is that which
is here required? Surely neither much, nor difficult: onely he muſt be ſure to keepe the ground
well with watering for a long time togither, to the end that it may be diſcharged of the overmuch
fat within it, which by this meanes will be waſhed well away, and the rankneſſe delaied. Yet as rich
and fertile as this ſoile is, the two rivers Euphrates and Tigris (which uſe to overflow and water
the countrey) bring no ſlimie mud with them, as Nilus doth in Ægypt, whereby the ground is
made ſo fat as it is: neither is the nature of the earth there, given to breed hearbs that it ſhould
need any weeding: and yet ſo plenteous and fruitfull it is, that it ſoweth it ſelfe againſt the next
yeere; for the corne that ſheddeth in the reaping and mowing, being troden under foot into the
ground, is as good as a ſowing, and riſeth of it ſelfe without any further labour.

Seeing then there is ſo great difference in the ſoile, I am put in mind therby to fit every ground K
with ſeed reſpectively, according to the nature and goodneſſe thereof. This therefore is the opi-
nion of *Cato*, That in a groſſe and fat ſoile, there would be wheat and ſuch like hard corne ſowne:
and if the ſame bee ſubject alſo to miſts and dewes, there may be ſowed therein Radiſh. Millet,
and Panicke, muſt be ſowed firſt in a cold and wateriſh ground; and afterwards for change, in a
hot ſoile. *Item*, the red bearded wheat Far or Adoreum, requireth a chalkie and ſandie ground,
and namely if it be well watered. *Item*, the common wheat loveth a drie ſoile, expoſed to the
ſunne, and not given much to breed ſuperfluous weeds. *Item*, Beans will doe well in a ſound and
faſt ſoile. As for Vetches, they care not how little they be ſowed in a moiſt peece of ground, and
ſuch as is apt to run to graſſe. Moreover, for the fine winter wheat Siligo, whereof the beſt man- L
chet is made, as alſo for the common frumentie wheat, there would be choſen an open & high
ground, lying pleaſantly upon the ſunne, that it may have the heat thereof to parch it as long
and as much as is poſſible. As for Lentils, they doe like a good rough and ſhrubbie ſoile, full of
red earth, ſo as it be not apt quickly to gather a green-ſord. * Barley would gladly grow upon a
* οἶτος ἐν πολλῷ πεδίῳ δ' ἐν κόπῳ. Plutarch. reſtie ground new broken up, or elſe ſuch as be in heart to beare every yeere. And as for ſummer
(barley) of three moneths, it would bee ſowne in a ground where it could not have an early or
timely Seednes, and which is ſo fat and rich, as it may affourd to beare crop, yeer by yeer. Finally,
to ſpeake to the purpoſe indeed, this alſo is *Catoes* wittie reſolution in one word for all: If the ſoile
be light and leane, ſeed it with ſuch graine or forage ſeed, as require no great nouriſhment, as for
example, with Cytiſus; and excepting the Cich peaſe, with all pulſe that are uſed to be plucked M
out of the earth, and not mowed downe: and thereupon indeed are theſe pulſe called in Latine
Leguminа, becauſe they are plucked and gathered in that ſort: but in caſe the ground be good
and fat, ſow ſuch things as require fuller food and nutriment; and namely, all garden woorts and
pothearbs; wheat, both the common and the fine; and Lineſed. Then, according to this rule, a

leane

A leane and hungrie ſoile will well agree with barley, for the root is contented with leſſe nutriture: whereas contrariwiſe we allow both lighter, and alſo more maſſie and richer ground for our ordinarie wheat. In a low and wet peece of ground, it is good to ſow the red wheat Adoreum, rather than the common wheat Triticum: but both it and barley will ſort well with a ſoile of a middle temperature. The hills yeeld a firme, faſt, and ſtrong kind of wheat, but the graine is but ſmall. And to conclude, the beſt kinds of wheat, to wit, Far and Siligo, challenge for their lot to be ſeared in a chalkie ſoile, and therewith alwaies wet and ſoked in water.

Chap. XVIII.

Of ſtraunge prodigies and wonders obſerved in corne: the knowledge and skill of
B *earing and tilling the ground: alſo divers ſorts of plough-ſhares.*

ALbeit I have in the title of this chapter purpoſed to write of prodigies ſeene in corne, yet to my knowledge, there never happened but once the like wonder and portenteous ſight to this which I ſhall tell, and which befell in the time that *P. Ælius* and *Cn. Cornelius* were Conſuls of Rome; that very yeare wherein *Anniball* with his whole armie was defeated and vanquiſhed: for then (by report) there was corne grew upon trees.

But foraſmuch as I have diſcourſed at large of the ſundrie kinds as well of corne as of ground, I will proceed now forward and come to the manner of ploughing the earth, after I have firſt ſet downe before all things elſe, how eaſie the husbandrie is in Ægypt: for there the river Nilus
C ſerving in ſtead of a good ploughman, beginneth to ſwell and overflow (as wee have before rehearſed) at the firſt new moone after the Summer ſunſtead. He beginneth faire and ſoftly, and ſo encreaſeth more and more by little and little; but all the while that the Sunne paſſeth under the ſigne Leo, he higheth apace untill he be riſen to his full heigth: being entred once into Virgo, his furie ſlaketh; then decreaſeth hee as faſt, untill he be falne againe into his wonted channell; which ordinarily happeneth by the time that the ſunne is in Libra. Now this is obſerved, That if he riſe not plumb above twelve cubits high, the people are ſure to have a famine of corne that yeere: the like alſo doe they make account of, in caſe hee paſſe the gage of ſixteene cubits: for the higher that he is riſen, the longer it is againe ere he be fully falne, by which time the Seednes is paſt, and men cannot ſow the ground in due ſeaſon. It hath been generally received for a
D truth, That preſently upon the departure of this deluge and overflowing of Nilus, they were woont to caſt their ſeed-corne upon the floten ground, and preſently let in their ſwine after for to trample it with their feet into the earth whiles it was ſoft and drenched. And verily, for mine owne part, I beleeve well, they uſed ſo to doe in old time: for even now adaies alſo, much more ado they make not about it. Howbeit, this is certein, that firſt they caſt their ſeed upon the ſlime and mud ſo ſoone as the river is downe, which commonly falleth out in the very beginning of November: which done, they goe over it with the plough and give it a light tilth, ſo as it may be covered only & lie under a ſmall furrow. Some few there be that afterwards fall to weeding, which point of husbandrie they call Botaniſmos: but the moſt part, after they have once ſowed and turned their ſeed into the ground, never after make a ſtep into field to ſee how their corne grow-
E eth, untill they go once for all with ſyth on necke or ſickle in hand, namely at the end of March; for then they fall to reaping and cutting it downe: ſo as by the moneth of May they ſung in Ægypt, Harveſt in, and all is done for that yeare. As touching this corne gathered in Baſe Ægypt, the ſtraw is never a cubit long: the reaſon is, becauſe the ſeed lyeth very eb, and hath no other nuttiment than from the mud and ſlime aforeſaid; for under it is nothing but ſand and gravell. But thoſe that inhabit higher up into the countrey, namely about Thebais, they be farre better provided for corne, becauſe Ægypt indeed (for the moſt part) lyeth low upon marais ground. Toward Babylon likewiſe and Seleucia (where the rivers Euphrates and Tigris doe ſwell over their banks and water the countrey) the ſame husbandrie is practiſed, but to better effect & greater profit, by reaſon that the people may let in the water at ſluces and floud-gates, more or leſſe
F with their owne hands, according as they liſt themſelves. Alſo in Syria, they have their ſmall ploughs for the nones to take a ſhallow ſtitch and make light worke: whereas in many places here with us in Italie, eight oxen are little enough to every plough, and to goe away withall they muſt labour at it till they blow and pant againe. It is an old ſaid Saw, and may goe for an oracle to be practiſed in all parts of husbandrie, but in this point of ploughing eſpeciall, *Bee ruled by*

the nature of every countrey, and see what each ground will abide. To come now unto our ploughs. G
Of Shares, there be many sorts: first, there is that instrument called a Culter, which serveth to make way before, cutting and cleaving the hard and thicke ground as it goeth, before it be broken up and turned atoneside: this sheweth by the slits and incisions that it maketh (as it were by a true line drawn) how the furrowes shall go; after which, commeth the broad bit of the ploughshare indeed, lying flatwise, and in earing casteth up all before it, and cleareth the furrow. A second sort there is, commonly used in many places, and it is no more but a bar of yron pointed sharpe in manner of a beake-head or stem of a ship; and it may bee called, a Rostle. And when the ground is not stubborne but gentle to be wrought, there is a third kind used, which is no
*Dentall. other thing but a peece of yron not reaching all over the * plough head and shooing it to the full, but turning up like a snout with a small point sharp at the end. This neb is somewhat broader H
in a fourth kind of shares, but as it is broader in blade and trenchant withall, so it is sharper also at the end, insomuch, that both with the point forward & the edges of the sides, it not only pierceth the ground before it poinctant like a sword, but also cutteth the roots of weeds which it encountreth: a devise invented not long since in Rhœtia. As for the Gauls, they set too besides, certaine small roundles or wheeles; & a plough thus shod & harnaised, they call in their language
* or as some thinke, *Pflugradt.* *Planarati: the head of their share is broad, fashioned like unto the bit of a spade: and thus they sow their grounds for the most part, new broken up and not tilled nor eared before. And for that their plough-shares be large and broad, so much the easier turne they up good turfs of earth and make broad furrowes. Presently after the plough, they throw in their seed, and mould or cover it afterwards with yron-toothed harrowes drawne aloft. Lands in this manner sown, need no other I
raking or weeding; for commonly they make not past two or three bouts in a land, and as many ridges. Finally it is thought, that in this manner there may be sowne in one yeere by the helpe of one yoke of oxen, fortie arpens or acres of land ordinarily, if the ground be gentle and easie to be eared; but if it be stiffe and stubborne, they shall have worke enough to go through thirtie.

Chap. xix.

The seasons that be proper for tilling the ground: also the manner of coupling oxen in yoke.

IN this operation of ploughing ground, I am of mind to follow that Oracle or Aphorisme of *Cato*, who being asked which was the first and principall point of Agriculture, answered K
* *bene colere.* thus, *Even to husband, order, and tend ground well:* being demaunded againe, what was the se-
* *bene arare.* cond, he made answer, *To plough well:* and when the question was propounded concerning the
* *bene stercorare.* third point of husbandrie, he said, *That it consisted in manuring and dunging it.* There bee other necessarie rules besides, set downe by him as touching this matter; namely, Make no unequall furrowes in ploughing, but lay them alike with one and the same plough. Passe not the kindly season, but eare the ground in due time. In the warmer countries, lands would bee broken up and fallowes made, immediatly after the winter Solstice or Sunstead. In colder regions, touch them not before the spring Æquinox or mid-March. In a drie quarter, plough more early than in a moist: sooner also in a fast and compact soile, than in a loose and light ground: in a fat and rich field, than in a leane and poore land. Looke in what climat the Summer is ordinarily drie L
and hot, it is thought more profitable to eare up a chalkie or a light and lean ground, betweene the summer Sunstead and the Æquinoctiall in the fall of the leafe. If the climat be such as yeeldeth but little heat in Summer, and therewith many showrs of raine, where the soile also is fat and beareth a thicke greene-sord, it were better to breake up ground and fallow in the hotest season: where the soile is heavie, grosse, and fat, and wherein a man may tread deepe, I like well that it should be tilled and stirred in winter: but in case it be very light and drie withall, it would not be
*In the Spring. medled with but a little before * Seednes. Here also be other proper rules set down by *Cato*, pertinent to Agriculture: Touch not (qd. he) in any hand a peece of ground that soon will turne to dust and mire. When thou doest plough indeed for to sow, employ thy whole strength thereto: but before thou take a deep stitch for all, give it a pin-fallow before; this commoditie commeth M
thereof, That by turning up the turfe with the botom upward, the roots of weeds are killed. Some are of this opinion, That howsoever we do els, a ground should have the first breaking up about the spring Æquinox. A land that thus hath ben once plowed in the spring, is called in Latin Vervactum, & hath that name of the foresaid time Ver, [*i.* the Spring.] Indeed ley grounds & such as

rest

A reſt ech other yeer, muſt be in this wiſe followed. Now if you would know what the Latins meane by Novale, they take it for a field that is ſowed every ſecond yeere. And thus much of the Land.

To come now unto our draught oxen that muſt labour at the plough: they ought to be coupled in yoke, as cloſe togither & as ſtreight as is poſſible, to the end that whiles they be at worke and ploughing, they may beare up their heads; for by that meanes they leaſt doe gall or bruiſe their necks. If they chaunce to goe to plough among trees and vines, they muſt be muzled with ſome frailes or deviſes made of twigs, to the end they ſhould not brouſe and crop off the young ſprings and ſoft tendrils. Moreover, there ought a little hatchet to hang evermore faſt to the plough beame before, therewith to cut through roots within the ground, that might breake or ſtay the plough: for better is it ſo to doe, than to put the plough to it, to keep a plucking at them,
B or to force the poore oxen to lie tugging and wreſtling with them. Alſo in ploughing, this order is to be kept, That when the oxen are * gone downe with one furrow to the lands end, they turne and goe up againe with another; ſo that in ploughing of a land they * reſt betweene-whiles as little as may be, but evermore goe forward in their labour untill they have made an end of their *halfe acre, or halfe daies worke: and verily it is thought ſufficient for a teeme of oxen to breake up (at the firſt tilth) in one day of reſtie or ley ground, one acre, taking a furrow or ſtitch of nine inches; but at the ſecond tilth or ſtirring, an acre and a halfe: which is to be underſtood, of an eaſie and mellow ſoile to be wrought: for if it be tough and churliſh, it is well if they eare up at the firſt, halfe an acre; and at the next time they may go through with one whole acre, how hard ſoever the ground be: for thus poore beaſts have their taske ſet, and their labour limited by Na-
C tures lore and appointment. Every field to be ſown, muſt be eared at firſt with ſtreight and direct furrowes; but thoſe that follow after, ought to goe byas and winding. If a ground upon the pendant or hanging of the hill bee to be broken up, the furrowes muſt goe croſſe and overthwart: howbeit, the point and beake of the plough ſhare muſt be ſo guided, that one while it bear hard above of the one ſide, and another while beneath on the other ſide: and verily in this mountaine worke, the ploughman that holdeth the plough hath toile enough, and laboureth at it as hard as the oxen doe. Certes, there bee ſome mountaines that have no uſe at all of this beaſt, but they eare their ground with raking and ſcraping hookes onely. The ploughman, unleſſe he bend and ſtoupe forward with his bodie, muſt needs make ſlight worke, and leave much undone as it ought to be; a fault which in Latine we call Prevarication: and this tearme appropriate unto Husban-
D drie, is borrowed from thence by Lawyers, and tranſlated by them into their courts and halls of pleas: if it be then a reprochfull crime for Lawyers to abuſe their clients by way of colluſion, we ought to take heed how wee deceive and mocke the ground, where this fault was firſt found and diſcovered. To proceed, the ploughman ever and anon had need to cleanſe the culter and the ſhare with his ſtaffe, tipped and pointed at the end like a thiſtle-ſpade: hee muſt beware that betweene two furrowes, he leave no naked balkes raw and untilled: alſo that the clots ride not one upon anothers backe. Badly is that land ploughed, which after the corn is ſowed, needs the great harrowes and clotting. Contrariwiſe, a man may know where there is good worke, namely, if the turfe be ſo cloſe couched that there be no ſeames to be ſeene where the plough-ſhare went. Finally, it is a profitable point of husbandrie and much practiſed (where the ground doth both beare
E and require it) For to draw here and there broad gutters or furrowes, to drain away the water into ditches and trenches caſt for the nones between the lands, that otherwiſe would ſtand within and drowne the corne.

Chap. xx.

Of harrowing and breaking clods. Of a certaine kind of ploughing uſed in old time. Of the ſecond tilth or fallow called Stirring: and of Cutting.

After the ſecond fallow called Stirring, done with croſſe and overthwart furrow to the firſt; then followeth clodding, if need be, either with rakes or great harrowes: upon which enſueth ſowing; & when the ſeed is in the ground, harrowing a ſecond time with the ſmall har-
F row. In ſome places, where the manner of the countrey doth ſo require, this is performed with a tined or toothed harrow, or elſe with a broad planke faſtened unto the plough taile, which dooth hide and cover the ſeed newly ſowne: and in this manner to rake or harrow, is called in Latine Licare, from whence came firſt the word Delicare, which is to leave bare balkes uncovered, and by a Metaphore and borrowed ſpeech, to rave and ſpeake idly.

It should seeme that *Virgil prescribed, that the ground should have foure tilthes in all, by these words, when he said, That the corne was best, which had two Summers and two Winters. But if the ground bee strong and tough, as in most parts of Italie, there needs a *fift tilth before sowing: and in Tuscane verily they give their ground, otherwhiles no fewer than nine fallowes, before it be brought into tillage. As for Beanes and Vetches, they may be sowed under furrow, without breaking up the ground before; for this is a readie way, gaining time, saving charges, and sparing labour.

And here I cannot overpasse one invention more as touching earing and ploughing the ground, devised in Piemont and those parts beyond the Po, by occasion of some hard measure and wrong offered to the people and paisants of that countrey during the warres. And thus stood the case. The Salassians making rodes into the vale lying under the Alpes, as they forraied and harried the countrey all over, assaied also to overrun their fields of Panicke and Millet being now come up and well growne, meaning thereby to destroy it: but seeing the nature of that graine to be such, as to rise againe and to checke this injurie, they set ploughes into it, and turned all under furrow, imagining by that meanes to spoile it for ever. But see! what ensued therupon? those fields thus misused (in their conceit) bare a two-fold crop, in proportion to other years; and yeelded so plentifull an harvest, as that thereby the paisants aforesaid learned the devise of turning corne in the blade into the ground, which I suppose in those daies when it new came up, they called Aratrare. And this point of Husbandrie they put in practise, when the corne begins to gather and shew the stem or straw, to wit, so soone as it hath put forth two or three leaves and no more.

Neither will I conceale from you another new devise, practised and invented first, not above three years past in the territorie of Treviers, neare to Ferrara. For at what time as their corn fields by reason of an extreame cold winter, seemed to be frost-bitten and spoiled, they sowed the same againe in the month of March, raking and scraping the upper coat of the ground onely without more adoe: and never in their lives had they the like encrease when harvest came. Now as touching all other Tillage and Husbandrie meet for the ground, I will write thereof respectively to the severall kinds of corne.

*Illa seges demum votis respondet avari Agricolæ, bis quæ sol: bis frigora sensit.

*1 Breaking.
2 Stirring.
3 Crushing.
4 Setting up.
5 Casting down.

Chap. xxi.

Of the tillage and ordering of the ground.

THe fine Wheat Siligo, the red bearded Wheat Far, and the common Wheat Triticum; Spelt or Zea (generally called Seed,) and Barley, when they be new sown, would be well clotted and covered first, harrowed afterwards, and weeded at the last to the very root; all at such seasons as shall be shewed hereafter. And to say a truth, every one of these is a sufficient worke for one man to doe in a day throughout an acre. As for the Sarcling or second harrowing, it dooth much good to corne: for by loosening the ground about it, which by the Winter cold was hardened, clunged, and (as it were) hide-bound, it is somewhat enlarged and at libertie against the Spring tide, and full gladly admitteth and receiveth the benefite of the fresh and new come Sunshine daies. Let him take heed who thus sarcleth or raketh the ground, that he neither undermine the roots of the corne, nor yet race or disquiet and loosen them. The common wheat, Barley, the Seed Zea, (*i.* Spelt) and Beanes, would doe the better if they were thus sarcled, and the earth laid loose about them twice. The grubbing up of weeds by the root, at what time as the corn is jointed, (namely, when the unprofitable & hurtfull hearbs are plucked forth and rid out of the way) much helpeth the root of the corne, discharging it from noisome weeds, procuring it more nutriment, and severing it apart from the other greene sourd of common grasse. Of all Pulse, the Cich pease asketh the same dressing and ordering, as the red wheat Far. As for Beanes, they passe not at all for weeding: and why? they overgrow all the weeds about, and choke them. The Lupines require nought else to bee done unto them but onely weeding. Millet and Panicke, must bee clotted and once harrowed untill they bee covered: they call not for a second raking and scraping about them, for to loosen the earth, and to lay fresh mould unto them; much lesse to be weeded. As for Silicia or Siliqua, *i.* *Fenigreeke, and Fasels, *i.* Kidney-Beanes, they care onely for clodding, and there an end.

Moreover, there be certaine grounds so fertile, that the corne comming up so thicke and rank in the blade, ought then to be kembed (as it were) & raked with a kind of harrow set with teeth or spikes

* For so he interpreteth it himselfe in the 16 chap. of this booke.

A ſpikes of yron: and yet for all this, they muſt be graſed or eaten downe beſides nevertheleſſe with Sheep. Now we muſt remember, that after ſuch cattell hath gone over it with their teeth, the ſame corne thus eaten downe, muſt of neceſſitie bee ſarcled, and the earth lightly raked and raiſed up freſh againe. Howbeit, in Bactriana, Affricke, and Cyrene, there needs no ſuch hand at all: for the climate is ſo good, ſo kind, and beneficiall, that none of all this paines is required: for after the ſeed is once ſowne, they never viſite it but once for all at nine moneths end, at what time they returne to cut it downe and lay it upon their thraſhing floores: the reaſon is, becauſe the drought keepeth downe all weeds; and the deawes that fall by night, are ſufficient to refreſh and nouriſh the corne.

Virgil is of opinion, That fallowes would be made every yeare, and that our corn field ſhould
B reſt betweene whiles, and beare but each other yeare. And ſurely, I doe find this rule of his moſt true, and doubtleſſe right profitable; in caſe a man have land ynough for to let his grounds play them, and reſt every ſecond yeare. But how if a man is ſtreighted that way, and hath no ſuch reach and circuit lying to his living? Let him helpe himſelfe this way: let him (I ſay) ſow his good red wheat Far againſt the next yeare, upon that ground from whence he gathered this yeare a crop of Lupines, Vetches, or Beanes, or ſome ſuch graine as doth enrich and mucke the ground. For this alſo is principally to be noted, that ſome corne is ſowne for no other purpoſe, but by the way as it were to advance and helpe others to fructifie: howbeit, ſmall fruit and encreaſe (to ſpeake of) ariſeth thereby, as I have obſerved once for all in the booke immediately going before, becauſe I would not willingly reiterate and inculcate one thing often. For herein regard eſpecially ought
C to be had, unto the nature and propertie of every ſoile.

Chap. xxii.

Of certaine countries exceeding fertile and fruitfull. Of a Vine bearing grapes twice in one yeare. Of the difference and diverſitie obſerved in waters.

THere is in Affricke or Barbarie a citie called Tacape, ſituate in the middeſt of the ſands, as men goe to the Syrts and Leptis the great: the territorie lying about which citie, by reaſon that it is ſo well watered, is marvellous fruitfull, and indeed paſſeth a wonder and is incredible. Within this tract there is a fountaine, which ſerveth abundantly for three miles well neere,
D every way; the head thereof verily is large ynough otherwiſe, howbeit the inhabitants about it are ſerved with water from thence by turnes, and diſpenſed it is among them at certaine ſet houres, and not otherwiſe. Ther ſtandeth there a mightie great Date tree, having under it growing an Olive, under which there is a Figge tree, and that overſpreadeth a Pomgranate tree, under the ſhade whereof there is a Vine: and under the compaſſe thereof, firſt they ſow Frumentie or eared corne, after that Pulſe, and then worts and hearbes for the pot, all in one and the ſame yeare. Every one of theſe rehearſed, live, joy, and thrive under the ſhade of others. Every foure cubites ſquare of this ſoile (taking the meaſure of a cubite from the elbow, not to the fingers ends ſtretched out in length, but claſped together into the fiſt) is ſold for *foure deniers Romane. But this one ſurpaſſeth all the reſt: The Vines in the ſaid territorie beare twice a yeare, and yeeld their
E grapes ripe for a double Vintage. So exceeding fruitfull is the ſoile, that unleſſe the rankeneſſe thereof were abated and taken downe, by bearing ſundrie fruits one under and after another, ſo that it were emploied to one thing alone, the inhabitants ſhould never have any good thereof: for by reaſon of the over-rankeneſſe, each ſeverall fruit would periſh and come to naught. But now by means of plying and following it ſtill with ſeed, a man ſhall gather one fruit or other ripe, all the yeare long. And for certaine it is knowne, that men cannot overcharge the ground, no nor feed the fertilitie of it ſufficiently.

*2 ſh. 6 d. ſterl. By which reckoning one acre would coſt above 20 pound ſterling: ſo much in proportion of the whole, as this cubit is under our halfe yard or 18 inches.

Moreover, all kinds of water are not of like nature nor of equall goodnes, for to drench and refreſh the ground. In the province of Narbone, now Languedoc, there is a famous well or fountaine named Orge, within the very head whereof there grow certain hearbes, ſo much deſired and
F ſought for by kine and oxen, that to ſeeke and get a mouth full of them, they will thruſt in their whole heads over their eares, untill they meet therewith. But howſoever theſe hearbes ſeeme to ſpring & grow within the water, certain it is, that nouriſhed they are not, but by rain from above. And therfore to conclude and knit up all in one word, Let every man be well acquainted with the nature both of his owne land which he hath, and alſo of the water wherewith he is ſerved.

G

Chap. xxiii.

Of the diverse qualities of the soile. Also, the manner of dunging or manuring grounds.

IF you meet with a ground of your owne, which wee called heretofore by the name of Tenara, the floure indeed and principall of all others: after you have taken off a crop of Barley, you may very well sow Millet thereupon: and when that is inned and laid up in the barne, proceed to Raddish. Last of all, after they bee drawne, there may bee Barley or common Wheat sowed in the place, like as they doe in Campaine: for surely such a peece of ground needs no other tillage, but often sowing. Another order there is besides this in sowing of such soile, namely, that where H there grew the red wheat Adoreum or Far, there the ground should rest all the foure Winter moneths, and in the Spring be sowed againe with Beanes; so that it alwaies be emploied & kept occupied untill Winter without any intermission. And say that the ground be not altogether so fat, yet it may be ordered so, that it be ever bearing by turnes in this sort, that after the Frumentie or Spike corn be taken off, there be pulse sowed three times, one after another. But in case the ground be over poore and leane, it must bee suffered to rest and take repose two yeares in three. Moreover, many Husbandmen do hold, that it is not good to sow white corne or Frument upon any land, but such as lay fallow and rested the yeare before.

However it be, the principall thing in this part of Agriculture, consisteth in dunging: whereof I have written alreadie in the former booke next to this. This one point only is resolved upon by I all men, that none of our grounds ought to be sowed, unlesse they bee manured and mucked before. And yet herein must we be directed by certaine rules peculiar and proper thereunto, as follow. Millet, Panicke, Rapes, Turneps or Navewes, ought never to be sowed but in a ground that is dunged. If there bee no compost laid upon a ground, sow upon it Frument or bread corne, rather than Barley. Likewise in grounds that rest and lie fallow every other yeare, albeit in all mens opinion, they are thought good for to beare Beanes, yet notwithstanding Beanes love better wheresoever they come to be sowed in a ground but newly mucked. Hee that mindeth to sow at the fall of the leafe, must in the month of September before, spread his dung, turne it in with the plough, and so incorporate it with the soile presently after a shower of rain. Even so also, if a man purpose to sow in the Spring, let him in the Winter time dispose of his mucke upon the lands and spread it. The ordinarie proportion is, to lay eighteen tumbrels or loads therof upon every acre. Thrown K abroad it must bee also before it bee dried, and ere you sow, or else so soone as the seed is in the ground, that it may be harrowed in with the corne. But in case this manner of dunging be neglected, it followeth then, before that you doe harrow, to strew the short small dung in manner of dust gathered out of Coupes, Mues, and Bartons, where foule are fed; or else to cast Goats-treddles upon the land, as if you would sow seed, and then with rakes and harrowes to mingle it with the soile.

To the end now that we may determine fully as touching this care also, belonging to dung, every sheepe or goat and such small cattell, should by right yeeld ordinarily in dung one load in *ten daies: and every head of bigger beasts ten load: for unlesse this proportion and quantitie of L mucke bee gathered, plaine it is, that the graunger or maister of Husbandrie, hath not done his part, but failed in littering of his cattell. Some hold opinion, that the best way of mucking a land is, to fold sheepe and such like small cattell thereupon, even in the broad open field; and to this purpose they enclose or imparke them within hurdles. In a word, a ground not dunged at all, groweth to be cold: and againe if it be overmuch dunged, the heart therof is burned away. And therfore the better and safer way is to mucke by little at once and often, rather than to overdoe it at once. The hotter that a soile is, it stands by good reason, that the lesse compost it requireth.

*or rather (after *Columella*) thirtie daies.

Chap. xxiiii.

Of good seed-corne. The manner of sowing ground well. How much seed of every kind of graine an acre will take. The due seasons of Seednes. M

THe best corne or Zea for seed, is of one yeares age, two yeares old is not so good: that of three, is worst of all: for beyond that time, the heart is dead, and such corn will never spurt.

And

A And verily this that is ſaid of one ſort, may bee verified of all kinds. The corne that ſettleth to the bottome of the mowgh in a barne toward the floore, is ever to be reſerved for ſeed. And that muſt needs bee beſt, becauſe it is weightieſt; for therein lieth the goodneſſe: neither is there a better way to diſcerne and diſtinguiſh good corne from other. If you ſee an eare of corn having graines in it here and there ſtaring diſtant aſunder, be ſure the corne is not good for this purpoſe, and therefore it muſt be caſt aſide. The beſt graine looketh reddiſh, and being broken betweene ones teeth, retaineth ſtill the ſame colour within: the worſe corne for ſeed is that, which ſheweth more of the white floure within.

Furthermore, this is certaine, that ſome grounds take more ſeed, and ſome leſſe. And hereby verily doe Husbandmen gather their firſt preſage religiouſly, of a good or bad harveſt: for when B they ſee the ground ſwallow more ſeed than ordinarie, they have a ceremonie to ſay and beleeve, that it is hungrie and hath greedily eaten the ſeed. When a man is to ſow a moiſt ground, good reaſon there is to make the quicker diſpatch, and to doe it betimes, for feare leaſt raine come to rot it. But contrariwiſe, in drie places it is not amiſſe to ſtay the later and attend till raine follow, leaſt by lying long in the earth, and not conceiving for want of moiſture, it looſe the heart, and turne to nothing. Semblably, when a man ſoweth earely, hee muſt beſtow the more ſeed and ſow thicke, becauſe it is long ere it ſwell & be readie to chit. But if he be late in his ſeednes, he ſhould caſt it thin into the ground, for thicke ſowing will choke and kill the ſeed. Moreover, in this feat of ſowing there is a pretie skill and cunning, namely, to carie an even hand, & caſt the ſeed equally throughout the whole field. The hand (in any caſe) of the ſeeds-man muſt agree with his gate C and march: it ought alwaies to goe juſt with his right foot. Herein alſo this would not bee forgotten, That one is more fortunate and hath a more luckie hand than another, and the ſeed will proſper better and yeeld more encreaſe that ſuch a one ſoweth: a hidden ſecret ſurely in Nature, and whereof we can yeeld no ſound reaſon. Over and beſides, this is to be conſidered, That corn comming from a cold ſoile, muſt not be ſowne in a hot ground; nor that which grew in a forward and haſtie field, ought not to be transferred into lateward lands. Howſoever, ſome there bee that have given rule cleane contrarie: howbeit, they have deceived themſelves with all their fooliſh curioſitie.

Now as touching the quantitie of ſeed that muſt be given, according to the varietie both of ground and grain, theſe principles following are to be obſerved. In a reaſonable good ground of D a meane temperature, an acre in ordinarie proportion will ask of common wheat Triticum, or of the fine wheat Siligo, five Modij; of the red wheat Far, or of *Seed [for ſo we call a kind of bread-corne] ten Modij; of Barley ſixe; of Beanes as much as of common wheat, and a fift part or one Modius over; of Vetches twelve; of Cich-peaſe the greater, Cichlings the leſſe, & of Peaſe, three; of Lupines ten; of Lentils three; [as for theſe, folke would have them ſowed together with drie dung] of Ervile ſix; of Silicia or Feni-greeke ſix; of Phaſeols or Kidney beanes foure; of Dradge or Balimong for horſe-provender, twentie; but of Millet and Panicke foure Sextars. Howbeit, herein can be ſet down no juſt proportion, for the ſoil may alter all. And in one word, a fat ground will receive more, and a leane leſſe. Beſides, there doth ariſe a difference another way, in this maner: if it be a maſſie, faſt, chalkie, and moiſt ground, you may beſtow in one acre thereof ſixe Mo- E dij, either of common wheat or of fine wheat Siligo; but in caſe it be looſe and light, naked, drie, and yet in good heart and free, it will aske but foure. For the leaner that a ground is, unleſſe it be ſowne ſcant, and the ſtraw come up alſo thin, the ſhorter eare will the corn have, & the ſame light in the head, and nothing therein. Be the ground rich and fat, yee ſhall ſee out of one root a number of ſtems to ſpring; ſo that although the graine be thin ſowne, yet will it come up thicke, and beare a faire and full eare. And therefore in an Acre of ground you ſhall not doe amiſſe, to keepe a meane betweene foure and ſixe Modij, having reſpect to the nature of the ſoile. And yet ſome there be that would have [of Wheat] five Modij ſowne at all adventure, and neither more nor leſſe, whatſoever the ground be. To conclude, if the ground be ſet with trees, or lying on the ſide of an hill, all is one, as if it were leane, hungrie, and out of heart. And hereto may be redu- F ced that notable Aphoriſme, worthie to bee kept and obſerved as a divine Oracle, Take not too much of a land, weare not out all the fatneſſe, but leave it in ſome heart. Over and above the Rules aforeſaid, *Accius* in his Treatiſe called Praxidicus, commeth in with one more of his owne, Sow your ground (ſaith hee) when the Moone is in any of theſe ſignes, Aries, Gemini, Leo, Libra, and Aquarius. And *Zoroaſtres* hath another Aſtronomicall obſervation

*He meaneth Zea or Spelt.

by

by himselfe, that the Sunne should be entred into Scorpio, and past twelve degrees thereof, the Moone being at the same time in Taurus.

Now followeth the deepe question to be discussed & determined, As touching the fit time and season of sowing corne: which I have put off and deferred to this present place. And this would bee handled and considered upon with exceeding great care and regard; as depending for the most part of Astronomie, and requiring good insight in the course and motion of the Planets, in the order also and influence of the fixed stars: and therefore I purpose to lay abroad the opinions and judgements of auncient writers principally in that behalfe. To begin therefore with *Hesiodus*, esteemed the prince and cheefe of all those that gave precepts of Agriculture; he hath set downe one certaine time of Seednes, to wit, presently after the fall or occultation of the star Vergiliæ, *i.* the Brood-hen: and no marvell, for he wrate that booke of his in Bœotia, a countrey in the very heart of Hellas or Greece, respectively to his owne countreymen and that climate: and in very truth that was the time of sowing there, as we have noted and specified alreadie. The best Authors of name, and who have written most exactly of this argument, are all agreed upon this point and conclusion, saying, That as all foules of the aire and four-footed beasts have their due season of engendring; even so there is a certaine time, when as the earth is as it were in the ruit, and hath a lust to be conceived. The Greekes in generall tearmes have described that season in this wise, namely, When the earth is hote and moist. *Virgil* giveth a precept to sow the common wheat Triticum, and the red bearded wheat Far, after the retrait or departure aforesaid of the Brood-hen Vergiliæ. As for Barley, he would have it cast into the ground between the Æquinox in Autumne, and the Winter Sunne-steed: but Vetches, Kidney beanes, and Lentils, at the setting or going downe of the star Bootes. Which being so, it would do well to digest the rising and falling both of these stars and also of others, into their set daies; to shew (I say) at what fixed time they appeare, and when againe they are hidden. Some there bee who are of opinion, That it is good sowing even before the occultation of the said star Vergiliæ, but in a drie ground only and in hote countries: for so (say they) will the seed swell & mortifie the better; which the naturall humiditie onely of the earth is sufficient to putrifie and prepare so, that when the next raine falleth, it will be readie to spurt and chit within a day. Others attend and wait seven daies after the retrait of the foresaid Brood-hen, for the raine that commonly falleth about that time. There be again that begin to sow in cold regions immediately after the Æquinox in Autumne: but in hot countries they be later in their seednes, for feare that the corne would bee Winter-prowd, and grow overmuch before the cold weather come. But all writers accord herein, that it is not good sowing about the Winter Solstice, when the daies be at the shortest: the reason is very pregnant & apparant, for Winter seed if it be sowne before midwinter, will spurt and spring at the seven-nights end; sow after that time, you shall have it lie in the ground fortie daies before it make any shew of comming up. Many make hast and put their seed into the ground betimes, and this proverbe they have usually in their mouth, *Well may overtimely and hastie sowing oftentimes faile, but late sowing shall ever misse and deceive the Maister*. Contrariwise, others there are of this mind, That it were better staying untill the Spring to doe it well & surely, rather than to sow in a bad Autumne, and put it to the hazard of loosing all. If there bee no remedie therefore, but to take the Spring season, a man must make choice of the time betweene the middest of Februarie [at what time as the West wind Favonius doth rise and begin to blow] and the Æquinox in March. Some have no regard at all to the constitution and figure of the heavens in this case; thinking the rising and falling of starres, the course and motions of cœlestiall bodies, to be frivolous matters & nothing pertinent to this purpose, but content themselves onely with observing the cardinall seasons of the yeare, and some other times, in a generalitie. In the Spring (say they) sow Lineseed, Otes, and Poppies, and so hold on unto the festivall holydaies of *Minerva*, called Quinquatrus; like as at this day throughout all Lombardie and beyond the Po, they goe by no other rule. As for Beanes, and the fine wheat Siligo, put them into the ground in the moneth of November. Let the Winter red wheat Far take his fortune and bee enterred, from the end of September, untill the middest or fifteenth day of October. Others goe beyond that day, and continue their Seednes unto the Calends or first day of November. Now, as these men have no regard at all to the speculation of Nature, and the course of the stars; so the other beforenamed, are given too much thereto, and rapt they are so high among the stars and planets, that their owne eies bee dazeled therewith: and besides, their subtilties and quiddities doe blind others, considering that the practise

A &tiſe of theſe matters muſt paſſe through the hands of ruſticall peaſants, who are ſo far off from conceiving Aſtronomie, & the conſtellations above, that they know not one letter of the book, nor never learned their A.B.C. Howbeit, wee cannot chuſe but confeſſe, that the true reaſon and knowledge of Agriculture, dependeth principally upon the obſervation of the order in heavenly bodies: for *Virgil* ſaith very well, That before all other things, a husbandman ſhould be skilfull in the winds, and have the foreknowledge and prediction of them: alſo to have an in-ſight into the nature and influence of the ſtarres: and in one word, to obſerve both the one and the other, as well as the Sailers and mariners at ſea. Certes, a hard peece of worke it is, and infi-nite; and ſmall hope I have that ever I ſhall be able to drive into their heads that are ſo ignorant and groſſe of conceit, this high learning and heavenly divinitie, as touching the Planets, the
B fixed Starres, togither with the reaſon of their orderly motions and cœleſtiall powers: howbeit conſidering the great profit that may ariſe and grow thereupon to mankind, I will caſt a proffer and give the attempt to make ploughmen Aſtrologers, or Aſtronomers at leaſtwiſe, if it may be. But firſt my purpoſe is, to lay open before their eies certaine difficulties (which troubled al-ſo ſome of the auncient writers, and thoſe not unskilfull in this part of Philoſophie) as touching the courſe and order of the Starres: which being not only diſcovered, but alſo aſſoiled and clee-red, their minds with better contentment may goe from the contemplation of heaven to the reſt of Natures workes, and ſee thoſe things by the effects, which they could not poſſibly foreſee by their cauſes.

C

Chap. xxv.

*The times and ſeaſons of the riſing and ſetting of Starres, digeſted into order, as well by * day as night.*

* i. Evening and morning.

IN the firſt place, there offereth it ſelfe unto us one difficultie above the reſt, ſo intricate, as hardly is it poſſible to reſolve upon it; namely, as touching the very daies of the yeare, how many they be in number; and the revolution of the Sunne, how and when he returneth again to the ſame point? For whereas ſome doe account the Solare yeere to be 365 daies juſt; others adde thereunto certaine quadrants or fourth parts of day and night togither, to wit, ſix houres every yeere; which being put togither, make the fourth yeare Biſſextile or Leape yeare: ſo as
D it is in manner impoſſible to aſſigne the certaine daies and houres of the Starres apparition or occultation. Over and beſides, how obſcure, how darke and confuſed all this matter is, appea-reth manifeſtly herein, That the times and ſeaſons of the yeare prefixed by auncient writers, fall not out accordingly; and namely, in the obſervation of the winter ſeaſons and tempeſts by them ſet downe: for one while you ſhall have them to prevent and come ſooner by many daies than ordinarie, which the Greeks call προχειμάζειν; another while to draw back and come later, which they tearme ἐπιχειμάζειν. Yea and for the moſt part this hapneth, by reaſon that the influence of the cœleſtiall ſtars reacheth ſooner or later to the earth, and thereafter ſheweth the effects: ſo as the common people, when they ſee the ſaid foule weather paſt, and all cleare and faire again, ſay then and not before, That ſuch a Planet or Star hath perfourmed his courſe, and is upon
E the point of his Tropicke or returne againe. Moreover, conſidering that all theſe occurrents de-pend much upon thoſe ſtarres which bee ſet and fixed in the firmament, yet ſhall yee have the Planets play their parts beſides, which by their motions and operations, worke no ſmall effects upon the earth, as we have ſhewed before; and namely, cauſing between-whiles ſtorms of raine and haile out of courſe: no marveile then, if they trouble our heads & put us out of our account, interrupting that order of the fixed Stars, upon which we conceived and built our hope of the faire ſeaſon, and our new ſpring. And herein, not wee onely that be men faile of our reckoning, but other living creatures alſo be deceived, which naturally have much more ſenſe & underſtan-ding of theſe workes of Nature, than wee, in as much as their whole life ſtandeth thereupon: for the Summer birds (as great fore-ſight as they have of ſuch ſeaſons and tempeſts) are over-taken
F and killed by Winter froſts and cold, comming ſooner than they looked for, and before they be gone out of the countrey: as alſo winter-foules miſcarrie by the hote weather of ſummer, con-tinuing longer than it was woont, and holding on ſtill after they be come. Hereupon it is, that *Virgil* expreſſely willeth us to learne throughly the skill of the wandering Stars or Planets alſo, and principally giveth us warning to marke the courſe of that cold Planet Saturne.

But

But now to come more particularly to the signes which fore-token the Spring: some there be that goe by the Butterflie, and hold that their brood comming abroad, is an assured token that the Spring is come, for that these creatures so feeble, are not able to abide any cold: howbeit, this was checked that very yeare, wherein I wrote this Booke or Historie of Natures worke: for seen it was and marked very well, that three flights of them one after another were killed with the cold weather that surprised them thrice, for that they were stirring too earely, and came abroad over-soone. Yea, and the very birds who are our guests in warme weather, visited us five or sixe daies before Februarie, and made a goodly shew of a timely Spring, putting us in good hope, that all cold weather was gone: howbeit, there ensued a most bitter after-winter streight upon it, that nipped and killed them in manner every one. Hard and doubtfull therefore is the case, that whereas first and principally we were to fetch our rule from the heavens to guide and direct us, then afterwards we should be driven to goe by other signes and arguments meere conjecturall. But above all, the cause of this incertitude and difficultie, is partly the convexitie of the cope of heaven, and partly the diverse climates observed in the globe of the earth: by meanes whereof, one and the same star seemeth to rise at sundrie times in diverse countries, and appeareth sooner or later to some than to others: and therefore the cause depending thereupon, is not in all places of like validitie, nor sheweth the same effects alwaies at the same times. And yet there is one difficultie more, arising from those Authors who writing of one and the same thing, have delivered diverse opinions, according to the sundrie climates wherein they were, at what time as they observed the figure and constitution of the heavens. Now were there of these Astronomers three Sects, to wit, the Chalcidians, the Ægyptians, and the Greekes. To which there may bee added a fourth, which among us *Cæsar* the Dictatour first erected: who observing the course of the Sun, and taking with him the advise also of *Sosigenes* (a learned Mathematician and skilfull Astronomer in his time) reduced the yeare unto the said revolution. Howbeit, in this calculation of his, there was found an error, and short he came of the marke which he aimed at, by reason that there was no bissextile or leape yeare by him inserted, but after twelve yeares. Now, when it was observed by this reckoning, that the Sunne had performed his revolution sooner than the year turned about, which before was wont to prevent the course of the Sunne, this error was reformed; and after every fourth yeare expired, came about the Bissextile aforesaid, and made all streight. *Sosigenes* also himselfe, albeit hee were reputed a more curious and exquisite Mathematician than the rest, yet in three severall treatises that he made, retracting or correcting that in one booke which he had set downe in another, seemed evermore to write doubtfully, and left the thing in as great ambiguitie and undetermined as he found it. As for these writers, whose names I have alleadged and prefixed in the front of this present volume now in hand, they have likewise delivered their opinions as touching this point: but hardly shall you find two of them in one & the same mind. Lesse marvell then, if the rest have varied one from another, who may pretend for their excuse the diverse tracts and climates wherein they wrote. As for those who lived in the same region, and yet wrote contrarie, I cannot tell what to make of them. Howbeit, I care not much to set downe one example of their discord and disagreement. *Hesiodus* the Poet (for under his name also there goeth a Treatise of Astrologie) hath put downe in writing the matutine setting of the star Vergiliæ (which is the occultation thereof by the raies and beames of the Sunne toward morning) to begin ordinarily upon the day of the Æquinox in Autumne. *Thales* the Milesian saith, That it falleth out upon the five and twentieth day after the said Æquinox. *Anaximander* writeth, That it is nine and twentie daies after: and finally, *Euctemon* hath noted the eight and fortieth day following the said Æquinox, for the retrait or occultation of the forenamed Brood-hen star Vergiliæ. Loe what varietie there is among these deepe clearkes and great Astrologers.

For mine owne part I hold well with *Cæsars* calculation, and will keepe me to his observations as neare as I can, for that the same will fit best with our meridian here in all Italie. Yet nevertheless I will not sticke to set downe the opinions of others, because my desseigne tendeth not to one particular place alone, but I purpose and professe to represent unto the Reader the universall Historie of Nature, and the whole world. But my meaning is not to rehearse the names of everie Author one by one (for that were a tedious peece of worke, and would require a long traine of superfluous words) but onely to put downe the regions of every climate, and that as succinctly and breefely as I can. Where, by the way I must advertise the Readers, that they remember well this one thing, how when for brevities sake I nominate the land or region Attica, they must withall

A all underſtand the Iſlands Cyclades: when I name Macedonie, I comprehend therewith Magneſia and Thracia: under Ægypt I compriſe Phœnice, Cyprus, and Cilicia: under Bœotia, the regions of Locris and Phocis: and in one word, alwaies the tracts and countries adjacent and confining together. *Item*, In making mention of Helleſpontus onely, I take together with it Cherſoneſus, and all the continent or maine firme land, as farre as to the mountaine Athos: in naming Ionia, I reckon alſo Aſia the leſſe or Natolia, and the Iſles thereto adjoining: under the name of Peloponneſus I count Achaia, and other lands in that climate lying to the Weſt. Finally, the Chaldæans ſhall make demonſtration, as in a map, of Aſſyria and Babylonia. As for Affricke or Barbarie, Spaine, and Fraunce, marvell not if I paſſe them over in ſilence: for there is not a writer in all theſe nations, one or other, who hath either obſerved or penned down the time when theſe
B fixed ſtars riſe or fall. Howbeit, it were no hard matter to come to the diſtinct knowledge thereof in thoſe climates and countries alſo, by the meridionall lines and conformitie of the Parallele circles, which I digeſted orderly in the ſixt booke of this worke. For thereby a man may underſtand the uniforme agreement in the poſition of the heaven, not onely for whole climates and countries, but alſo for every ſeverall cittie by it ſelfe, under the ſame meridian or Parallele: following ſtill the knowne paralleles of theſe regions which we have named, and taking withall the elevation of any circle pertaining to every ſuch land as a man will ſeeke, and reſpective to the riſing of the ſtars, according to the equall ſhaddowes, throughout all thoſe parallele circles. Moreover, it ought to be ſhewed and declared that ordinarily the times and ſeaſons have their temperature and influence every foure yeares together: and thoſe lightly returne the ſame without any great
C alteration, from yeare to yeare duly according to the courſe and recourſe of the Sunne, during that tearme: marie in eight yeares they ſenſibly doe encreaſe, namely by what time as the Moone is in her hundreth revolution.

Now all the knowledge of the heavens pertinent to Agriculture, ſtandeth principally upon three ſorts of obſervations, to wit, The riſing of the fixed ſtars; the ſetting of the ſame; & the four cardinall points, to wit, of the two Tropickes or Sunſteads, and the double Æquinox, which devide the whole yeare into foure quarters and notable ſeaſons. Where note, that the riſe and fall of thoſe ſtars beforeſaid is to be conſidered and taken two waies. For firſt when the Sunne approcheth unto them with his beames, they be hidden and no more ſeene: likewiſe, after his departure they ſhew themſelves againe: and as the one, me thinkes, might have been more aptly called an Apparition than a Riſing, ſo wee ſhould have framed our tongue in common ſpeech to
D have tearmed the other Occultation, rather than Setting. Secondly, according as the ſaid ſtars begin either to ſhine out or bee hidden in the morning before the Sun be up, or at evening after the Sunne is ſet, they be ſaid to riſe and goe downe; and thereupon are named * Matutine or Veſpertine, Orientall or Occidentall, according as the one or the other happeneth unto them in the twy-light, morning or evening. Certes, when they are to be ſeene Matutine or Veſpertine, it muſt be at the leaſt three quarters of an houre either before the Sunne is up, or after he is downe: for within that ſpace there is no looking after them. Moreover, ſome ſtars there bee that riſe and fall twice. But take this with you, ere I proceed further, that all this ſpeech of mine is to bee underſtood of the fixed ſtars, which beeing ſettled faſt in the skie, move not of themſelves: and in no
E wiſe, of the Planets.

As touching the foure cardinall ſeaſons of the yeare, whereby it is devided into foure quarters: limitted they be according to the light more or leſſe, and as the daies be longer or ſhorter: for ſo ſoone as the Winter Sunneſtead is paſt, the daies do lengthen; and by that time that ninetie daies and three houres be gone and paſt, they be juſt as long as the night, & this is called the Spring Æquinox. From which very day for ninetie three daies together & twelve houres, namely, unto the Summer Sunneſtead, the daies be longer than the night, and ſo continue untill the Autumne Æquinox, at what time the daies and nights be equall againe; from which time they ſhorten and decreaſe as they grew in length & encreaſed before, for eightie nine daies together, and three houres, untill the foreſaid Winter Sunneſtead, when as the daies bee ſhorteſt. And
F here you muſt note, that in all theſe additions of houres at this preſent, I meane thoſe onely that be Æquinoctiall, which devide the day and night equally in foure and twentie parts, and not the common houres of any other day artificiall whatſoever. Alſo take this with you, that all theſe diſtinctions and diviſions of the foure ſeaſons, begin alwaies in the eight degree of thoſe ſignes under which the Sunne is at thoſe times: as for example, The winter Sunneſtead or ſhorteſt day

of

* ortus & occaſus Heliacus.

* ortus & occaſus Coſmicus.

of the yeare, called in Latine Bruma, falleth out in the eight degree of Capricorn, which lightly is upon the *18 day before the Calends of Ianuarie. The Spring Æquinox, when nights and daies be of a length in the eight degree of Aries. Semblably, the Summer Sunneſtead or longeſt day of the yeare, is alwaies when the Sunne is entred eight degrees into Cancer. Laſt of all, the other Æquinox in Autumn, when day and night is equall, lighteth upon the eight degree of Libra. And certes, ſeldome or never ſhall you ſee any of theſe foure daies without evident ſhew of ſome notable change in the weather. Againe, theſe cardinall ſeaſons or quarters of the year, admit alſo their ſub-diviſions ſtill into ſome notable and ſpeciall times, obſerved in *the very middle ſpace from the one and the other. For betweene the Summer Sunneſtead and the Æquinox in Autumne juſt upon the five and fortie day after the ſame Sunneſtead, the retrait or ſetting of the ſtar called in Latine Fidicula, *i.* the Harpe, beginneth the Autumne. Likewiſe, betweene that Æquinox and the Winter Sunneſteed or ſhorteſt day of the yeare, the Matutine or morning fall of the ſtar Vergiliæ, upon the three and fortieth day after the ſaid Æquinox, ſetteth the beginning of the Winter. So likewiſe upon the five and fortieth day betweene mid-winter or the ſhorteſt day of the yeare and the Spring Æquinox, the blowing of the Weſterne wind Favonius beginneth the Spring. And laſt of all, upon the three and fortieth day from the ſaid Æquinox toward the Summer Sunneſteed, at what time as the ſtar Vergiliæ doth riſe Matutine, begins the Summer.

* 15 of December.

*Called *Intervalla* afterward in this chapter: and containe much about ſix weekes.

But to returne againe to our Agriculture, begin I will at the Seednes of Frument corne, that is to ſay, at the riſing or apparition of the ſtar Vergiliæ in the morning, without making any mention at all of other petie ſtars, for to interrupt the traine and courſe of our Treatiſe, and to heape difficulties one upon another; conſidering that the fierce and vehement ſtar Orion is departed a great way off from us by that time. I am not ignorant, that many fall to ſowing corne long before, & prevent this time, beginning their Seednes within eleven daies after the Æquinox in Autumne, namely, at the approch and riſing of the ſtar Corona, *i.* the Crowne: promiſing themſelves aſſuredly to have raine upon it for certaine daies together. *Xenophon* would not have us begin to ſow before that God give us ſome good ſigne and token ſo to doe. And *Cicero* our countreyman expounding this ſaying of *Xenophon*, taketh the raines in *November to bee that ſigne which God giveth: whereas in very deed the true and undoubted rule to goe by, is to make no great haſt into the field for to ſow, before the leaves begin to fall; and this every man holdeth to be at the very occultation or retrait of the ſtar Vergiliæ. Some as we have beforeſaid, have obſerved it about three daies before the Ides of November: and for that the ſaid ſtar is ſo evident in the heaven, and eaſieſt to be knowne of all others, called it is by the name of a garment hanging out at a Brokers ſhop. And therefore by the fall or retrait thereof, as many men as have a care and fore-caſt to prevent the covetous dealing of the merchant Taylor (as commonly ſuch occupiers lie in the wind for gaine) gueſſe aforehand what Winter will follow: for if it bee a cloudie ſeaſon when this ſtar doth retire, it threateneth a rainie Winter, and then theſe merchants preſently raiſe the price of the clokes which they ſell: but if the weather be faire and cleare at the ſetting or occultation thereof, it ſheweth a pinching and hard Winter toward: and then they hold other garments alſo very deere. But this Husbandman of ours, who cannot skill at all to look up and to learne the order and poſition of the heavens, muſt ſpie this ſigne of Winter among his briers and brambles, hee muſt find (I ſay) the time of Seednes as hee lookes downeward upon the ground, namely, when hee ſees the leaves fallen and lying under his feet. Thus may a man know the temperature of the climate, and the yeare, according as hee perceiveth the leaves bee fallen more at one time than another, ſooner alſo in ſome places, and later elſewhere. For as the ſeaſon is forward or late, as the climate alſo is affected, ſo are the trees knowne to ſhead their leaves accordingly. And in very truth, this is the trueſt ſigne of all others. And the beſt thing therein is this, that being generall throughout the whole world, and yet peculiar to each place, it never faileth. A man might make a wonder hereat, if hee did not ſee and remember, that upon the very ſhoreſt day in the year, even in midwinter when the Sun is entred Capricorn, the hearb Peniroyall uſeth of it ſelfe to floure, either ſet in chaplets, or otherwiſe hanging and ſticking in the ſhambles; ſo willing is Nature to ſhew us all her ſecrets, and to keepe nothing hidden from us. For loe what ſignes and markes ſhe hath given us, whereby we might know the time of ſowing corn: and verely, this is the onely true and infallible direction, grounded upon approoved experience, and the ſame ſhewed firſt by dame Nature; for by this dropping and fall of leaves, what doth ſhe elſe

*Called by our Husbandmen Gore-moone.

teach

A teach and counſell us but to have our eie upon the ground, and to caſt ſeed into it: aſſuring us of a certaine ſupplie of dung and compoſt by overſpreading the ground with ſuch mullock, that ſoone will turne into mucke? what doth ſhee elſe (I ſay) but by covering the earth in this manner with leaves, ſhew how carefull ſhe is to defend it againſt hard froſts and pinching winds, and in one word, thereby putteth us in mind to make the more haſt and get our ſeed under mould? As for *Varro*, he is of the ſame opinion for Beanes alſo, and willeth us to obſerve the ſaid rule in ſowing them at the fall of the leaſe. Others are of this mind, that the beſt ſowing thereof is in the full Moone. But for Lentils, we ſhould attend the laſt quarter toward the chaunge, to wit, from the five and twentieth day to the thirtieth. Alſo, that Vetches muſt be ſowed at the ſaid age of the Moone: for in ſo doing we ſhall preſerve ſuch pulſe from the naked ſnaile. Howbeit, ſome others B there bee, that indeed would have theſe kinds of pulſe to bee ſowed at this time of the yeare and age of the Moone for provender and forrage to be ſpent out of hand; marie if wee would keepe the ſame for ſeed, then we ſhould take the ſeaſon of the Spring.

Beſides thoſe rules and tokens above ſpecified, there is one more, which Nature upon an extraordinarie providence over us, hath preſented unto our eies after a wonderfull manner, the which *Cicero* expreſſeth in theſe tearmes:

Iam vero ſemper viridis, ſemperq́; gravata
Lentiſcus, triplici ſolita eſt grandeſcere fœtu:
Ter fruges fundens, tria tempora monſtrat arandi.

C
The Maſticke tree,
All times you ſee,
Is clad and richly dight,
With greene in cold,
With fruit three-fold,
A faire and goodly ſight.

As ſhee therefore,
By Natures lore,
Doth fruit thrice yearely beare:
So thereby wee,
Know ſeaſons three,
Our land to duly eare.

Of which three ſeaſons, one is appropriate for the ſowing both of Poppey and alſo of Lineſeed. But ſince I have named Poppey, I will tell you what *Cato* ſaith as touching the ſowing thereof: Vpon that land (quoth hee) where you meane to ſow Poppey, burne your winding rods; the D cuttings alſo and twigs of vines, which remained and were left at the pruning time; when you have burnt them, ſow wild Poppey ſeed in the place; for it is a ſingular medicine beeing boiled up to a ſyrrup in honey, for to cure the maladies incident to the chawes and throat. As for the garden Poppey, it hath an excellent and effectuall vertue to procure ſleepe. And thus much concerning Winter corne and the Seednes thereof.

Chap. xxvi.

A ſummarie and recapitulation of all points of Husbandrie: and to what outworkes in the field a Husbandman ſhould be employed, reſpectively to every moneth of the yeare.

E

BVt now to compriſe under a certaine brieſe Abridgement and Breviarie, all points of Huſbandrie togither: At the ſame time before-named, [to wit, at the fall of the leaſe] it is good alſo to lay dung unto the roots of trees; likewiſe to mould and banke vines: and one workman is ſufficient for one acre. Alſo, where the nature of the ground will bear it, the husbandman ſhall not doe amiſſe to disbraunch and lop his tree-groves, to prune his vineyards, to hollow the ground of his ſeminaries and nource-plots with mattocke and ſpade, & dreſſe the mould light; to open his ſluces and trenches for water-courſe, to drive and draine it out of the fields; and finally, to waſh his wine-preſſes firſt, and then to ſhut and lay them up drie and ſafe. *Item*, after the Calends or firſt day of Novembre, let him ſet no Hens upon egs untill the winter Sunſtead F be paſt: when that time is come and gone, ſet Hens hardly, and let them couve thirteene egs; marry better it were all ſummer long to put ſo many under them: for in winter fewer will ſerve; howbeit never under nine.

Democritus giveth a gueſſe what Winter we ſhall have, by the very day of the Winter Sunſtead: for looke what weather is then and for three daies about it, the like winter (he ſuppoſeth) will

will enſue. Semblably, for the Summer, hee goeth by the other Sunſtead or longeſt day of the yeare: and yet commonly for a fortnight about the ſhorteſt day in the yeare, (to wit, during the time that the foules Halcyones doe lay, couve, and hatch their eggs in the ſea) the winds lie and the weather is more mild and temperate. But as well by theſe ſignes as all other whatſoever, we muſt gueſſe the influences and effects of the Stars, according to the event, within ſome latitude of time; and not ſo precisely to limit and tie them alwaies to certaine daies prefixed, as if they were bound to make their appearance peremptorily in court, juſt then, and faile not.

Moreover, in mid-winter, meddle not at all with vines, touch them not in any hand, but let them alone. What then is the Husbandman to doe? Mary then (quoth *Hyginus*) after ſeven daies be once paſt from the Sunſtead, he is to refine his wines from the lees and let them ſettle, yea and to poure them out of one veſſell into another, provided withall, that the moone be a quarter old. Alſo about that ſeaſon (to wit, when the Sunne is in Capricorne) it is not amiſſe to plant Cherritrees, and ſet their ſtones: then is it good alſo to give oxen Maſt to feed them; and one Modius or pecke is ſufficient to ſerve a yoke at one refection: allow them more at once, you glut them and fill them full of diſeaſes: but at what time ſoever you make them this allowance, unleſſe you hold on thirtie daies togither, (folke ſay) they will be ſcabbed and mangie when the ſpring commeth, that you will repent for cutting them ſo ſhort. As for felling timber trees, this was the proper ſeaſon which we appointed heretofore. All other winter workes for an husbandman to be buſied in, would be done in the night for the moſt part: ſit up hee muſt late, and riſe betimes by candle-light, and watch hardly about them, for that the nights bee ſo much longer than the daies: let him a Gods name, find himſelfe occupied with making wicker baskets & hampers, winding of hurdles, and twiſting of frailes and paniers: let him thwite torch-wood taperwiſe for linkes and lights: and when he hath by day-light made readie and prepared thirtie poles or railes for vines to run on, and ſixtie ſtakes or props to ſupport them, hee may in the evening make five poles or pearches, and ten forkes or ſupporters; and likewiſe as many early in the morning before day-light.

But now to come to *Cæſars* reckoning of the times and digeſtion of the cœleſtiall ſigns: theſe be the notable ſtarres which are ſignificant and doe rule that quarter which is betweene the winter Sunſtead and the riſing of the Weſterne wind Favonius. Vpon the third day (ſaith hee) before the Calends of Ianuarie, which is the thirtieth day of December, the Dog-ſtarre goeth downe in the morning: upon which day in Attica and the whole tract thereto adjoyning, the ſtarre Aquila, [*i.* the Ægle] ſetteth (by report) in the evening, and looſeth her light. The even before the Nones of Ianuarie, *i.* the fourth day thereof by *Cæſars* account [I meane for the meridian of Italie] the Dolphin ſtarre riſeth in the morning, and the morrow after, the Harp-ſtarre Fidicula: upon which day, in Ægypt, the ſtarre Sagitta, [*i.* the Arrow] ſetteth in the evening. *Item*, from that time to the ſixth day before the Ides of Ianuarie, [*i.* the eigth day of that month] when as the ſame Dolphin goeth downe or retireth out of ſight in the evening, uſually we have in Italy continuall froſt and winter weather: as alſo when the ſunne is perceived to enter into Aquarius, which ordinarily falleth out ſixteen daies before the Calends of Februarie, [*i.* the ſeventeenth of Ianuarie.] As for the cleare and bright ſtarre called the Star-Royall, appearing in the breaſt of the ſigne Leo, *Tubero* mine authour ſaith, that eight daies before the Calends of Februarie, to wit, the 25 day of Ianuarie, it goeth out of our ſight in the morning: alſo over night before the Nones of Februarie, [*i.* the fourth day of the ſame moneth] the Harpe-ſtarre Fidicula goeth downe, and is no more ſeene. Toward the latter end of this quarter, it is good and neceſſarie to dig and turne up freſh mould with mattocke and ſpade againſt the time that roſes or vines ſhall be ſet, whereſoever the temperature of the climat will beare it: and for an acre of ſuch worke, ſixtie labourers in a day are ſufficient to doe it well. At which time alſo, old trenches and ditches would be ſcoured or new made. For morning worke before day, the husbandman muſt looke to his yron tooles, that they be ground, whetted, and ſharpned; that their ſteales, helves, or handles, be fitted and ſet to their heads; that ſhaken tubs, barrels, and ſuch like veſſels, be new cowped, bound with hoops, and calfretted; that their ſtaves be well ſcraped and cleanſed, or elſe new ſet into them. And thus much of this Winter quarter, as farre as to the comming of the Weſterne wind Favonius.

Now as touching the entrance of the new Spring, which is from the riſing of the ſaid wind to the Æquinox in March: *Cæſar* ſetteth downe for it the time, which for three daies togither is variable

A tiable and inconſtant weather, to wit, ſeventeen daies before the Calends of March, which is the thirteenth of Februarie. Alſo eight daies before the ſaid Calends, which is the 22 of Februarie, upon the ſight of the * firſt Swallow; and the morrow after, upon which day the ſtar Arcturus riſeth Veſpertine, *i.* appeareth in the evening. In like manner, *Cæſar* hath obſerved, that the ſaid wind hath begun to blow three daies before the Nones of March, to wit, the fifth of March, juſt with the riſing or apparition of the Crab-ſtar Cancer. Howbeit moſt writers of Aſtrologie do aſſigne the firſt entrie of the Spring and the comming of this wind, to the eigth day before the Ides of March, which is the eigth of that moneth, when as the ſtar Vindemiator, *id eſt*, the Grape-gatherer, beginneth to appeare: at what time alſo the Northerly ſtarre called the Fiſh, doth ariſe: upon the morrow whereof, to wit, the ninth day, the great ſtarre Orion ſheweth

B himſelfe in his likeneſſe. In the region Attica where Athens ſtandeth, it is obſerved, that the ſtar Milvus, *i.* the Kite or Glede, appeareth then in that climat. *Cæſar* moreover noted, that the ſtar Scorpio riſeth upon the * Ides of March, thoſe fatall Ides (I ſay) that were ſo unfortunate unto himſelfe: alſo, that upon the 15 Calends of Aprill, which is the 18 of March, the foreſaid Milvus, *i.* the Kite-ſtar, appeareth to them in Italie: and three daies after, the Horſe-ſtar is hidden toward the morning. This is the freſheſt, the moſt buſie and ſtirring Intervall or time betweene, that husbandmen have; and yet therein be they ofteneſt deceived, for commonly called they are not to their worke the very ſame day that the wind Favonius ſhould by courſe blow, but when it begins to be aloft; which is a point to be conſidered and obſerved with right great regard: for if a man would take heed and marke well, this is that moneth wherein God giveth us that ſure

C and infallible ſigne which never faileth. Now from what quarter or coaſt this wind doth blow, and which way it commeth, albeit I have ſhewed alreadie in the ſecond booke of this ſtorie, yet will I ſpeake thereof more diſtinctly and exactly anon; meane while, from that day (whenſoever it hapneth) on which that wind beginneth to blow, come it ſooner (as namely, when it is a timely and forward Spring) or come it later, if it be a long winter (for it is not alwaies the * ſixth day juſt before the Ides of Februarie) from that time, I ſay, muſt the ruſticall paiſants fettle to their worke, then are they to goe about a world of toileſome labour, then muſt they plie their buſineſſe and make ſpeed to diſpatch thoſe things firſt that may not be deferred and put off: then or never would their ſummer three-month corne be ſown, their vines be pruned in manner aboveſaid, their Olive trees dreſſed and trimmed accordingly: Apple-tree ſtockes and ſuch like fruits,

D are then to be ſet and graffed; then is the time to be digging & delving in vineyards, to remove ſome young plants out of their ſeminaries, and digeſt them in order as they muſt grow, and to ſupply their plots with new ſeeds and imps: Canes and Reeds, Willows and Oſiers, Broome alſo would then ſome be ſet, and others cut downe: Elmes, Poplars, and Plaue trees, ought then to be planted, as hath been ſaid before: then is the meeteſt ſeaſon to cleanſe the corne fields, to ſarcle and rid the winter-corne from weeds, and eſpecially the bearded red wheat Far: in doing whereof, this muſt be the certein rule to direct the husbandman, namely, when the root of the ſaid Far begins to have four ſtrings or threeds to it. As for Beans, they muſt not be medled withall in that order, before they have put out three leaves; and then verily they muſt be lightly gone over, and cleanſed rather with a light hooke, than otherwiſe. When Beanes be blowmed, for fif-

E teen daies togither they ought not to be touched. As touching Barley, it would not be *ſarcled or raked, but in a drie ground, and when the weather holds up. Order the matter ſo, that by the Æquinox in March, all your pruning and binding of vines be done and finiſhed. If it be a vineyard, foure men are enough to cut and tie an acre of vines: and if they grow to trees, one good workeman will be able to overcome fifteene trees in one day. This is the very time moreover of gardening and dreſſing roſe-plots or roſiers [whereof I meane to treat apart and ſeverally in the booke next following] of drawing vinets alſo, knots, and fine ſtorie workes in gardens: this is the only ſeaſon to make trenches and ditches: the ground alſo would now be broken up for a fallow againſt the next yeare, according to the mind and counſell of *Virgil* eſpecially, to the end that the Sunne might throughly parch and concoct the clots, and thereby make it more mellow for the Seednes. Howbeit I doe like better of their opinion (as the more thriftie and profitable of the twaine) who adviſe to plough no ground in the mids of Spring, but that which is of a mean temperature: for if it be rich and fat, preſently the weeds will over-grow & take up the ſeams and furrowes: againe, ſay it be poore and leane, the hot weather comming ſo ſoone upon the fallow, will dry it too faſt, ſpend all the moiſture, and kill the heart thereof, which ſhould maintaine the

* Whereupon the ſaid wind *Favonius*, is called *chelidonias* and *Orneathias*.

* 13 of March: for upon that day was hee murdred.

* *i.* the ſeventh of Februarie.

* *Sarrire.*

ſeed to be ſowne therein. *Cato* ſetteth downe the Husbandmens worke for the Spring time, in theſe tearmes: Caſt trenches (quoth he) couch young braunches, and interre them for ſeminaries by way of propagation, in caſe the ground bee ſtrong, fat, and moiſt withall. Lay dung to your Elmes, Fig trees, Apple trees, and others of like fruit; to Olives alſo doe the like: neither forget to manure and muck your medow grounds; but all in a drie moone & about the change. Such fields as are not well watered, defend them as well as you can from the Weſt wind Favonius: downe with ſuperfluous weeds and rid them out of the way; but and if they be hurtfull beſides, plucke them up by the roots. Cleanſe Fig trees betweene, where need is: make new ſeminaries and nource-gardens, and repaire the old. All this would be done before the vine begin to floure. Moreover, ſo ſoone as the Peare tree ſheweth bloſſome, begin to plough leane, light, and ſandie grounds; but afterwards you may be bold to goe in hand with the fatteſt, faſteſt, and moſt wateriſh that be: let theſe (I ſay) be laſt tilled. And to conclude briefly, as touching this time of ploughing, let this be the marke and rule to guide you; namely, to ſet unto your worke and put plough in ground, when you ſee either the Lentiske tree to ſhew the hope of her firſt fruit, or the Peare tree to bloſſome and have a white head. There would bee alſo a third tilth or cruſhing of the ground, obſerved by the ſea-onyon Squilla, among thoſe hearbs which have bulbous roots: likewiſe among floures, by the Daffodill. For as theſe do bloume thrice, ſo they point unto three times of ploughing. For by their firſt bloſſome, they ſhew the firſt tilth or breaking up of the ground, by their middle flouring, the ſecond fallow or ſtirring: and by their third, the laſt cruſhing. Wherein a man may ſee the wonderfull chaine (as it were) that linketh this world together, whereby all creatures therein contained, give lightſome tokens and ſignes one to another. And this may bee obſerved alſo in the yvie (a thing verily not of the leaſt and laſt regard) which muſt not in any caſe be touched or meddled withall, ſo long as Beanes bee in their bloume; for that is the very time and meane to hurt it moſt and kill it for ever. Now, as ſome plants there bee that ſerve for ſignes unto others, ſo there be other that carie about them their owne marke, as for example, the Fig-trees: for looke when they put forth in the head a few leaves hollow, and with the edges turning upward in manner of a ſawcer or goblet, be ſure that is the right ſeaſon & beſt time to plant them.

Now is it time to returne from whence wee were digreſſed, namely, to the calculation of the principall times and quarters of the yeares, and namely, to the Spring Æquinox, which ſeemeth to be come and gone alwaies by the 8 day before the Calends of Aprill, to wit, the 25 of March. From which day forward, by *Cæſars* calculation, the Calends of Aprill, to wit, the firſt day of Aprill are ſignificant, as whereupon the ſtar Vergiliæ, *i.* the Brood-hen, beginneth to riſe or appeare in the morning; howſoever in Attica and the parts thereabout, the ſaid ſtar ſeemeth to ſet or be hidden in the evening upon the third day before the Nones of Aprill, *i.* the third of that month: and the morrow after, the ſame ſtarre doth the like in Bœotia. Howbeit, according to *Cæſars* Ephemerides for Italie, and the Chaldæans for Aſſyria and Babylon, the foreſaid ſtarre goeth downe or retireth out of ſight upon the Nones of Aprill, *i.* the fift of Aprill: at what time in Ægypt, as well *Orion* as his Sword [both ſtars in heaven ſo called] begin to be hidden. After *Cæſars* reckoning, the ſigne or ſtar Libra ſetteth in Italy the ſixt day before the Ides of Aprill, which is the eigth of the ſame moneth, and ſignifieth ſtore of raine. The fourteenth day before the Calends of May, which is the eighteenth of Aprill, the * Suculæ (a violent and troubleſome ſtar, cauſing ſtormes and tempeſts raging both on land and ſea) goe downe at evening in Ægypt; but in Attica two daies before, to wit, the ſixteenth of Aprill: and in Italy, by *Cæſars* booke, the day betweene both; that is to ſay, the ſeventeenth day of the ſaid moneth; the influence whereof is effectuall for three daies togither: but in Aſſyria it falleth out twelve daies before the Calends of May, *i.* the ninteenth of Aprill. This is the ſtar or ſigne in the heavens, commonly named Palilicium; becauſe the eleventh day before the Calends of May, *i.* the 20 of Aprill, the very birthday and memoriall feaſt of Rome cities foundation (on which day the weather commonly cleareth up and is faire againe) gave folke a notable occaſion of obſerving the ſaid ſtars retreat or occultation: howſoever the Greekes have tearmed them * Hyades, by reaſon of the rain and foule weather which ordinarily they bring. And whereas our countreymen have called them in Latine Suculæ, *i.* porkets or ſmall ſwine (according to the apparent Greeke denomination, which they thought to be derived of ὗς, ſounding in Latine *Sus*, *i.* a ſwine) their ſuppoſall was falſe, and bewrayed their great ignorance. Moreover, *Cæſar* noteth the eighth day before the Calends of May,

* or *Hyades*, which ſome ſay, are five in nũber, as *Heſiodus*: others ſeven, as *Proclus*,

* ἀπὸ τῦ ὕειν ἢ ὑετῦ, *i.* of rain.

A May, which is the 24 of Aprill, for the time that the ſtar Hœdi, *i.* the Kids, doe riſe in Italy: but the next day after, they are obſerved to appeare in Ægypt: the morrow following, within Bœotia and Attica, the Dog-ſtar is marked to be hidden and gone in the evening, when as the Harpe-ſtar is ſeene in the morning. Now the day after that, which is the fifth day before the Calends of May, *i.* the 27 of Aprill, in Aſſyria Orion is quite hidden; and two daies after, the Dog-ſtar. Alſo the ſixth day before the Nones of May, which is the ſecond of that moneth, *Cæſar* obſerveth, That in Italy the foreſaid ſtarres Suculæ, riſe matutine and ſhew in the morning: like as alſo the rainie Goat-ſtar Capella, upon the eigth day before the Ides of May, which alſo is the eigth day of that moneth: and the very ſame day the Ægyptians doe obſerve in their countrey, that the great Dog-ſtar goeth downe in the evening, and is no more ſeene. Thus you ſee how theſe fixed
B ſtars and ſignes above rehearſed, doe ordinarily keepe their courſes, ruling and governing this time betweene, to wit, from the ſpring Æquinox in March, unto the ſixth day before the Ides of May, which is the ninth of the ſaid moneth. During the firſt fifteene daies of which halfe quarter, the husbandman muſt make haſt and take in hand that worke which he was not able to goe through with and diſpatch before the Æquinox; knowing full well, that upon neglect of this buſineſſe, aroſe firſt, the opprobrious reproches that vine-tuners and cutters doe heare on both ſides of their eares, from paſſengers and wayfaring men, by way of counterfeiting the ſong of that Summer-bird which they call the Cuckow: for it is counted ſo foule a ſhame, worthie a checke and rebuke, that the ſaid bird ſhould come and find a pruning hooke or bill in a vine at that time of the yeare; that folke therefore ſtick not to let flie at them bold taunts, and broad bi-
C ting ſcoffes, even in the firſt beginning of the Spring. And verily as theſe birds, ſo their ſong counterfeited in this ſort, ſeemeth to carrie an ominous and curſed preſage with them. See how the leaſt things belonging to Agriculture, are guided and caried by naturall reaſons! As for the later end of this foreſaid time, it muſt be employed in the ſowing of Panicke and Millet; for it is ordinarie and uſuall to ſow this kind of graine after that haſtie Barley is ripe, and alſo upon the very ſame lands where it grew. Now the ſigne common to them both, teſtifying as well the ripeneſſe of the one as the Seednes of the other, are the Glo-birds or Glo-wormes Cicindelæ, ſhining in the evening over the corne fields: for ſo the ruſticall paiſants and countrey clownes call certaine flies or wormes glowing and glittering ſtar-like; and the Greekes name them Lampyrides: wherin we may ſee the wonderfull bountie and incredible goodneſſe of Nature, in teaching
D us by that ſillie creature.

Chap. xxvii.

That Husbandmen ſhould not gaze at ſtarres ſo much, but rather goe by the ſeaſons of the yeare meet for ſowing. Alſo, that they ſhould marke the riſing, the ſetting, and the courſe of the Sun in ſome hearbes. And of the riſing and ſetting of other ſtars.

E NAture contented not her ſelfe to aſſemble a troupe of ſtars together in a knot (I meane the Brood-hen Vergiliæ, whereby it is a ſigne in heaven above, conſpicuous ynough alreadie, and of great mark) but ſhe would needs give the Husbandman other ſtars beneath upon the earth, as ſignes to ſhew him the true ſeaſons and times when and how to goe to worke: as if ſhee cried out and ſpake unto him after this manner: Why ſhouldeſt thou looke up to the heavens, thou that art to till thy ground? Why keepeſt thou a ſeeking among the ſtars for thy countrey worke? Take thy reſt and repoſe thy wearied lims good man, for the nights bee now ſhorter than they were: to bed therefore, for thou haſt but a while to ſleepe: Behold I ſcatter and ſpread here and there among thy very weeds and graſſe growing upon the ground, other eſpeciall ſhining ſtars, and thoſe I repreſent unto thine eies in the evening, & when thou doeſt unyoke and give over thy daies worke: and that thou ſhouldeſt not either plead ignorance, or neglect the ſame, I provoke thee to regard and looke thereat, as a ſtrange wonder. Seeſt thou not theſe
F flies or glo-birds aforeſaid cover their bright and glittering light, reſembling ſparckles of fire, when they keepe their wings cloſe together, and carie fire-light about them even in the night? More than ſo, I have given thee certaine hearbes to tell thee what is a clocke, and how the day goes: and to eaſe thee more, that thou needeſt not paine to avert thine eies away from the earth where thy worke lieth, and caſt them ſo much as up to the Sunne; loe the hearbe Heliotropium

and the Lupine, turne about with him. What ſtandeſt thou ſtaring ſtill into the skie, and holdeſt up thy noſe aloft into the aire? why art thou amuſed upon the courſe of the ſtars, and ſearcheſt into heaven? Haſt thou not I pray thee another Brood-hen ſtar, other Vergiliæ, I ſay, even before and under thy very feet, I meane theſe pretie glo-wormes? Surely theſe come duly at their ſet daies: theſe keepe time juſt with thoſe of the heaven, and ſo long as they appeare and ſhine above, theſe gloe and glitter beneath: as if they were linked to that ſtar by ſome neere alliance and affinitie: in ſuch ſort, as a man may reſolve and hold for certaine that engendred they be no otherwiſe but by the influence therof, and are the very chickens and brood of the foreſaid Hen. And therefore conclude we may, that whoſoever ſoweth his ſummer corn, and looketh to reape fruit accordingly before theſe are to bee ſeene, deceiveth himſelfe, and looſeth all his coſt and paines. In this meane time and ſpace betweene, the pretie Bee commeth abroad, and telleth us that Beanes bloume, for it is the Beane bloſſome that calleth her forth of her hive.

Wouldſt thou know another ſigne yet, that winter is paſt and all the cold cleane gone? when thou ſeeſt the Mulberrie tree to bud and put out young leaves, feare no more froſt nor hard weather to doe any harme for that yeare. Then (hardly) go to thy worke appropriate for this ſeaſon: now is it good to plant young ſions and quick-ſets of Olives; now is the time to ſcrape & cleanſe here and there where need is, the old Olive trees; and now would meddows be watered, even preſently after the Æquinox. What is elſe to be done in the field this Spring time? Mary, ſo ſoone as the graſſe in the meddow is growne to a ſtem and begins once to ſpindle, then let foorth the water, and draine your meddowes. Then doe the Vines looke for to be disburgened and rid from their ſuperfluous leaves and needleſſe branches: And herein there is a certain gage ſet, and a rule to goe by, namely, when as the ſaid burgeons are ſhot out foure fingers in length. Where, note by the way, that the disbraunching of an acre in Vineyard, is one mans work a day and no more. This is the ſeaſon to give corne lands their ſtirring, that is to ſay, the ſecond tilth or fallow. As for the ſarceling or weeding of [Winter] corne, it would bee done within twentie daies. For let this Æquinoctiall ſeaſon paſſe, it is thought that ſarceling and weeding will hurt not only corne, but vines alſo. To conclude, this is the very time alſo to waſh ſheepe.

And now to come againe unto our ſtars where we left. The morrow after the riſing or apparition of the ſtar Vergiliæ beforeſaid, *Cæſar* reckoneth, that the ſigne Arcturus looſeth his light and is hidden in the morning. Alſo, that the third day before the Ides of May, to wit, the thirteenth of that moneth, the Harpe ſtar ariſeth and begins to ſhine. Moreover, twelve daies before K the Calends of Iune, which is the one and twentieth day thereof, the Kid-ſtar goeth down in the evening: at what time as in the region of Attica the Dog-ſtar alſo ſetteth after the ſame manner. The next day after (by *Cæſars* account for the Meridian of Italy) Orions Sword beginneth by little and little to retire and goe out of our ſight. The third day before the Nones of Iune, *i.* the third day of that moneth (after *Cæſars* Ephimerides for our climate of Italie, as alſo according to the Chaldæans calculation for the Meridian of Aſſyria) the Eagle-ſtar beginneth to riſe and appear in the evening. In which region, Arcturus goeth downe, and wee looſe the ſight thereof in the morning, eight daies before the Ides of Iune, which is the ſixt of the month: howſoever with us here in Italie, he ſetteth two daies later. As alſo two daies after that, *i.* the tenth of Iune, the Dolphin ſtar appeareth and giveth light in the evening. But ſeventeene daies before the Calends of L Iulie, which is the fifteenth of Iune, we in Italie ſee the riſing of Orions Sword, which they in Ægypt do obſerve foure daies after. And eleven daies before the ſaid Calends, to wit, the one and twentieth day of Iune, the ſame ſtar (I meane the Sword of Orion) beginneth to go down and be obſcured in Italie, if *Cæſars* Almanacke bee true. Now are wee come to the eight day before the Calends of Iulie, namely, that foure and twentieth day of Iune, the very longeſt day and ſhorteſt night of the whole yeare, and the Summer Sunneſtead. In this ſeaſon alſo be vines disburgeoned and cleanſed from their unprofitable leaves and branches: then required it is, and care would be had, that an old Vineyard ſhould have once digging, and the new, twice. This is the time of ſheepe-ſhearing. Now, would Lupines bee turned in with the plough, for to enrich and manure the ground. Now are the lands to be cruſhed and ſet up againſt the ſeed time. Now Vetches would M ſtand no longer, but bee cut for to make forrage. Beanes alſo would bee now mowed downe, and thraſhed out of the way ſoone after.

CHAP.

A

Chap. xxviii.

Of meddowes and lay grounds for hay and paſture. The manner how to refreſh and repaire a meddow. Of ſith-ſtones and whet-ſtones: of Siths and Sickles. Alſo, the time for ſowing corne, and the deſcription of thoſe fixed ſtars that governe this ſeaſon.

THe ordinarie ſeaſon to mow meddowes, is about the Calends or beginning of Iune. And verely, albeit theſe kind of grounds aske leaſt care and toile about them for to bee maintained, and ſtand the Husbandman in as little charges, yet ſomething would bee ſaid thereof,
B and theſe few rules following obſerved. Firſt therefore, a ground would be hained in, left lay, and kept for graſſe and hey, which is for ſoile good and fat, for ſituation lying either low and moiſt, or elſe having water at commaund from a brook or river neare at hand: but above all, if it be poſſible, it muſt lie ſo, that it may have the benefite of the raine by letting in land-flouds into it (running along the lanes and high waies) for to refreſh and water the ſame. Alſo it is paſſing good otherwhiles to plough up a meddow ground [for the graſſe will come and grow afterwards the better] ſo it be well harrowed or raked thereupon, and laid even and levell. Provided alwaies, that hey-ſeeds, flowers & all, be ſowed upon it (ſuch as be found in hey-lofts and ricks, or els that ſhed out from the racke into the crib or maunger) which would bee done before the ſame ground bee harrowed as is aboveſaid. Howbeit, neither ought a meddow that is laid for hey and paſture, bee
C watered the firſt yeare, ne yet graſed with cattell, before the ſecond math; for feare leaſt the beaſts pluck up the graſſe quite ere it be well rooted, or kill the heart thereof by ſteining and trampling it under their feet. Moreover, it is to bee noted, that ſuch meddow grounds in time will age (as it were) and decay: in which regard, they ought to be helped and reſtored to their heart againe, by ſowing therein either Beanes, Rapes, Navews, or Millet: and when you have taken a crop of one of theſe from thence, the yeare following they would bee ſowne with ſome Frument or bread-corne: and ſo the third yeare left lay for meddow againe. Over and beſides, this would not be forgotten, that at every math, ſo often as the graſſe is mowed for hey with the ſyth, there come one after with an hooke, to cut downe thoſe tufts and manes which the mowiers paſſed over and left ſtanding behind them: for there is nothing worſe for a meddow, than to ſuffer graſſe grow to
D ſeed. The beſt hearbe in a meddow is the Claver graſſe or Trefoile: next to it is the common graſſe called Gramen, *i.* Coich or Dogs-tooth: the worſt is *Mimmulus. Alſo the Camocke or Whin, called Reſt-harrow, and ſuch like codded graſſe, is not for mowiers, for they crie out upon ſuch and curſe it. Moreover, they cannot away with the hearbe Equiſetis, *i.* Horſe-taile, ſo called for the reſemblance it hath to an horſe-taile or mane.

* Some read *Nummulus*, i. *Nummularia*, Peny-graſſe.

The fit time to mow downe graſſe, is when the ſpike or head thereof beginneth once to ſhed flowers, and to waxe ſtiffe: for in no caſe muſt it ſtand untill it be drie and withered. Bee not too late (quoth *Cato*) in your hey harveſt, but downe with your meddowes, before the ſeed of your graſſe bee ripe. Some, the day before that they ſet ſyth into their meddowes, water them, if there be a brooke at hand to be let in. And indeed the beſt cutting downe of graſſe is preſently upon
E ſome good dewes that have fallen overnight. * In ſome parts of Italie the manner is to cut their meddows after corne harveſt. Moreover, in old time it was more coſtly and painefull to mow (by far) than it is now adaies: for they uſed no other whetſtones, but ſuch as were knowne and ordinarie, as brought out of Candie and from beyond ſea; which would not give an edge to their ſythes and make them keene, without they were whetted with oile [as Barbers doe their raſours, and gravers their fine chezils and carving yrons:] and to that purpoſe the mowier went ever with a horn full of oile, tied faſt to his ſhanke. Since which time there have been found in Italie other maner of grindſtones, with water, which will bring any yron toole to an edge quickly, aswell as a file. But theſe water grindleſtones ſoone get a ſwarth and preſently become greene.

* Haply he meaneth a ſecond math.

As touching the very Sythes, there bee two ſorts of them. For thoſe of Italie be ſhorter than
F other, eaſie to handle and weld, and it were among buſhes, briers, and brambles. In France where their fields and meddowes be large, they goe a nearer and ſhorter way to worke, for they make no more adoe, but cut the graſſe down at the middle, and let that alone which is ſhort. Our mowiers here in Italie, take but one hand to it, and that is commonly their right, and ſo cut downe their graſſe: thus you ſhall have a man ordinarily in one day goe over an acre and cut it downe clean.

Alſo

Alſo it is one mans worke to bind the hey of one acre into bottels: and uſually you ſhall have in ſo much ground* 1200 pretie ones, of foure pound weight apeece. So ſoone as the graſſe is cut downe and laid in ſwath, it muſt bee tedded, brought into windrowes, and turned eftſoones with the Sunne: neither ought it to be cocked up but drie: for otherwiſe, if this bee not carefully looked unto, you ſhall ſee it reeke and ſmoke again by the morning, for the heat that it hath caught within: but let the Sunne take it beſides, you ſhall bee ſure to ſee the cockes kindle and bee of a light fire. G

*Which is almoſt three of our ſale lodes.

So ſoone as this firſt graſſe is downe and the hey made, the meddow muſt preſently be watered againe, to the end there may be a ſecond math of rowen hey in * Autumne, which the Latines call Cordum. In the territorie of Interamna they uſe commonly to mow their meddowes foure times a yeare, yea, though they lie high and far from the benefit of water. And in moſt places of Italie, thrice is ordinarie: and the rowen graſſe afterwards commeth up ſo thicke and high for paſture and forrage, that it yeeldeth as great a benefit as the crops of hey before: marie, to raiſe this commoditie and gaine, thoſe know full well who are drovers of greater cattaile, breeders alſo of young colts, and principally, chariottiers that keepe coach-horſes; for all theſe have the beſt meanes to employ this graſſe for their moſt behoofe. H

*Some call it woodcock hey.

To proceed now to the conſideration of the heavens. The Summer Sunneſtead, falleth out alwaies [in Italie] to be juſt upon the foure and twentie day of Iune, at what time as the Sunne is entred eight degrees within Cancer, as hath been ſaid before. This is that great point and Tropicke of the world: now is the heaven in moſt force, and the Sunne at the higheſt of his power and vertue. From the midwinter or ſhorteſt day of the yeare, unto this preſent, during the ſpace of ſix moneths the daies lengthen: and now the Sunne being paſſed farre into the North, and having mounted and raught to the higheſt pitch of his intended laborious journey, beginneth to turne againe from this Tropicke of Cancer in the North, and bendeth his courſe toward the other Tropicke of Capricorne in the South; intending by this meanes for other ſix moneths to lengthen the nights and to ſhorten the daies, proportionably. Which the Husbandman no ſooner ſeeth, but he taketh his opportunitie, and woteth well, that now is the time wherein hee muſt of neceſſitie make haſt to gather and inn the fruits of the yeare, each one reſpectively in their ſeverall ſeaſons: now or never ought hee to lay in his proviſion againſt the Winter: now muſt hee arme and prepare himſelfe (no remedie) to withſtand the rigor of cold and froſtie weather. And therfore meet it was, that dame Nature (our kind nource and tender mother) ſhould give us warning hereof, and foreſhew this alteration of the yeare, by moſt undoubted and infallible arguments. Hereupon ſhe hath preſented theſe markes and ſignes to the Husbandman, and brought them even to his hand: commaunding ſundrie trees upon that very day of the Sunneſtead to turne their leaves toward the Sunne, as if ſhee pointed unto them by the finger, and ſhewed how that Planet began to retire from whence hee came: ſo willing ſhe is, not to conceale from him theſe ſecrets, that ſhee hath not ſet theſe markes upon wild and ſavage trees far remote out of the way, (becauſe ſhe would not have him take ſo much paines as to go into deſert forreſts, unpaſſable wields and mountaines, to ſeeke for the ſignes and tokens aforeſaid) ne yet upon ſuch as grow within good townes and citties, much leſſe then thoſe that ſerve and are in requeſt for arbors and vinets onely in hortyards and gardens of pleaſure, that he ſhould be faine to leave his ferme in the countrey and goe thither (and yet theſe trees alſo teſtifie of the Sunneſtead and his returne:) what hath ſhe done then? Marie ſhe hath cauſed the Olive tree, which he ſeeth every hour planted at his very foot, to turne about her leafe: ſhe hath willed the Linden, a tree that hee hath recourſe unto every foot for a thouſand uſes, to doe the like: ſhe hath enjoined the white Poplar or Aſpe alſo the ſemblable, wedded as it is ſo commonly to Vines. Haſt not thou ynough yet (quoth ſhe) and will not all this make thee perfect? Look then to the Elme, at the foot wherof thou planteſt thy Vine, and which thou ſeeſt continually endowed and enriched therewith, I will make it alſo to turne the leafe when the Sunne returnes. Thou ſtrippeſt her of her leaves and braunches for thy cattell to eat and brouſe; thou getteſt up into it for to prune the Vine; How canſt thou chuſe but ſee the leaves turned? How canſt thou be ignorant, but take knowledge of the Solſtice and Sunnes returne? Surely that ſide of the leafe which was from the Sunne but yeſterday, is now cleane contrarie, and lookes toward him; and in one word, all are turned upſide downe. Thou occupieſt the oiſier and willow twigs ever and anone, to bind and tie one thing or other; loweſt they grow of all the reſt, and higher thou art than they by the head: never look up nor caſt thine I K L M

eie

A eie aloft for the matter: thou ſhalt ſee how I will have them alſo, growing even under thy noſe, to turne their leaves about and follow the Sunne. Why complaineſt thou and whineſt, ſaying, I am a ſimple countreyman, I am not booke-learned, I never went to Grammer ſchoole, and I wot not what? Certes, I cannot doe withall if thou be ignorant of the heavens, and canſt not skill of the cœleſtiall ſigns and courſe of the ſtars: it ſhall not be long of me, but thou maiſt be an Aſtronomer and Clearke ſufficient. For if all this teaching will not ſerve, in caſe, I ſay, thine eies will not inſtruct thee ynough to learne theſe ſignes: one ſigne more will I preſent unto thine eare. Doe but liſten to the groning tune and pitifull mone that the Quoiſt and Stock-dove makes: and never thinke that the Sunneſtead is paſt, before ſhe have left ſinging, and that thou ſeeſt her coave and ſitting upon her egs.

B But now to goe on ſtill with our Aſtrologie and Speculation of Heaven as wee have begun: among thoſe ſtars that rule this ſeaſon from the Sunneſtead beforeſaid, unto the ſetting or occultation of the *Harpe-ſtar; *Cæſar* ſaith, that ſix daies before the Calends of Iulie, to wit, the ſix and twentieth of Iune, Orion riſeth to the inhabitants of Italie: howſoever the ſtar called Orions *girdle, appeareth not to the Aſſyrians before the fourth day of Iulie, upon which day, in Ægypt the ſtar Procyon, *i.* the fore-runner of the Dogſtar Syrius ſheweth in the morning, and commeth in very hote and fierie: and ſurely what Latine name this ſtar ſhould have among the Romanes, I wote not, unleſſe we would have it to bee Canicula, that is to ſay, the Leſſe Dog ſtar, according to the pourtrait that it ſeemeth to reſemble among thoſe fixed ſtars in the firmament: and yet is this a ſigne in the heaven of great marke and conſequence, as anone we will declare more plainely. The third day before the Nones of Iulie, *i.* the fift of the ſaid moneth, after the Chaldæans account, in Aſſyria and Babylon, the ſtar named Corona, *i.* the Crowne, goeth downe in the morning: but on the very ſame day to the people of Attica, Orion is ſeene to riſe all whole as hee is. The even of the Ides of Iulie, which is the foureteenth of that moneth, the ſame Orion ceaſeth to be ſeene of them that dwell in Ægypt: and ſixteene daies before the Calends of Auguſt, to wit, the ſeventeenth of Iulie, the foreſaid ſtar Procyon riſeth to them in Aſſyria. The morrow after, which is the eighteenth day, all writers in manner doe agree upon the riſing of that ſignificant and notorious ſigne, which commonly we call the Dog-ſtar, to wit, when as the Sunne is entered the firſt degree of Leo, which falleth out to be the three & twentieth day after the Summer Sunſtead. And in truth both ſea and land doe find and feele the arrivall or comming of this ſtar, yea,

D and many a wild beaſt beſides, according as we have ſhewed already in place convenient. Neither is this ſtar leſſe worſhipped and adored than thoſe renowmed Planets which carie the names of gods and goddeſſes, and have divine honours done unto them. He it is that enflameth and ſetteth the Sunne on fire: to him is imputed the greateſt cauſe of that extreame hot weather, during the canicular daies. Two daies before, which is the fifteenth of Iulie, in Ægypt, the Æagle ſtar goeth downe in the morning, and then the Eteſian winds (called the Avant-curriers) begin, which *Cæſar* thought were not felt nor knowne in Italie untill eight daies after, namely, the three and twentith of Iulie: on which day the Ægle ſtar is knowne to ſet and goe out of ſight in the region of Attica and that tract, in the morning. As for the Roiall ſtar ſeated in the breaſt of Leo, *Cæſar* affirmeth, That it goeth downe and is all hidden betimes in the morning, the thirtieth day of Iulie, which

E is three daies before the Kalends of Auguſt. Now the eight day before the Ides of Auguſt, which is the ſixt day of the month, the one moietie or halfe of Arcturus goeth down: but the third day before the ſame Ides, which is the eleventh of that moneth, the Harpe ſtar by his occultation or going downe, beginneth Autumne, according as the ſame *Cæſar* noteth: but indeed and verely, as it hath been found by true demonſtration, it is the ſixt day before the Ides, to wit, the eight of Auguſt. This halfe quarter or ſix weekes ſpace, is that which determineth of vines and vintage, by the meanes of that ſtar which we called Canicula, the very ruler indeed over Vineyards, and whereupon dependeth the good or bad ſeaſon for all our grapes and wine the next yeare. From hence it is, and not otherwiſe, that the Vines are ſaid to be blaſted, & the grapes burnt (as it were) to a coale. No haile ſtormes, no tempeſt of wind or raine is comparable hereunto, nor doth the

F like harme to corne and grapes: this cauſeth many a time ſcarcitie, and bringeth extream dearth and famine, which neither haile nor tempeſt doth. As for theſe tempeſts, they endomage haply and hurt ſome fields here and there: but the blaſt beforeſaid plagueth whole countries, farre and neare. Howbeit, it were no hard matter to deviſe how to withſtand and remedie this miſcheefe, but that men take more pleaſure to take occaſion for to blame Nature and her workes, under pre-

tence

tence and colour of ſuch untoward blaſts, than to ſeeke and find meanes to do themſelves good. G
It is reported of *Democritus*, the firſt Philoſopher who underſtood himſelfe, and afterwards ſhewed unto the world, the great affinitie and agreement that was between heaven and earth (which ſundry of his the richeſt and wealthieſt citizens where he lived, ſeemed to ſcorne and deſpiſe) foreſeeing by the courſe of the ſtars, & namely, by the riſing that would be of the Vergiliæ or Brood-hen (according as I have ſhewed alreadie, and will anon declare more at large) that Olives would faile that year, and conſequently a dearth enſue of oile; bought up all the oile in that tract & countrie, which as then for the hope of great plentie of Olives, bare no price: whereat the great merchants of the citie (who dreamed of nothing leſſe than of a ſcarſitie of oile, conſidering the Olives made ſo fair a ſhew upon the trees) were aſtonied & marvelled much, that *Democritus* ſo learned a Philoſopher, & a man who they knew, was wont by his profeſſion to content himſelfe with poverH tie, to ſet his mind upon nothing ſo much as a quiet life, & wholly to buſie his braine in attaining of knowledge and learning, was now on a ſuddain become a merchant. In the end, they perceived what the cauſe was, & acknowledged his divine skill in foreſeeing & preventing a dearth: and he for his part ſhewed plainly, That it was not avarice and deſire of lucre that moved him to take this courſe, but to let the world know, that if he were ſo diſpoſed, he could by the means of his learning only, be ſoon a rich man (as indeed he grew hereby to exceeding wealth:) for preſently of his own accord he reſtored again unto the former owners, who God wot were diſpleaſed with themſelves for that they had done, & wiſhed withall their harts, that they had met with the like bargaine; he remitted (I ſay) all this commoditie which he had gotten into his own hands, at their owne price: reſting herein, that he had made good proofe, how ſoon & eaſily he could be rich whenſoever he I
would. Long time after him, *Sextius* one of our Roman Philoſophers, did the like at Athens, and after the ſame manner: whereby we may ſee, in what ſtead learning and literature ſerveth, if a man will employ the ſame to his own benefit. And I care not much verily to give the countriman a taſt thereof, as much as may concern the cauſe of the Blaſting aforeſaid, and to intermeddle the ſame with his ruſtick affairs, but as plainly and with as great facilitie & lightſomeneſſe as poſſibly I can. Moſt are of this opinion & have delivered in writing, That as well the blaſting in corn called Ruligo, as the ſindging & burning of vines named Carbunculus, proceed from certain dews ſetling upon them, which caught a cauſticke qualitie from the acrimonie and extraordinarie heat of the Sun. This conjecture and reaſon of theirs, I hold in ſome part to be falſe, for the Sun never doth harme either to the one or the other in this reſpect; but looke what blaſt ſoever it be that ſindK geth or burneth corne and vines, it is occaſioned by cold onely: and if you take good heed and marke how this commeth about, you will ſay it is cleare and paſt all peradventure: for firſt and foremoſt this is well knowne, That it never hapneth but in the night, or at leaſtwiſe before the Sunne is riſen: ſo as we may conclude well and truly, that all this dependeth upon the influence of the moone. For never ſhall a man ſee any of theſe hurtfull blaſts, but either about the change or full of the moone, that is to ſay, when ſhee is in her greateſt force: for at both theſe times, as well in the conjunction with the Sunne, as in oppoſition, powerfull ſhee is, and in ſome ſort may be tearmed Full, as I have many a time alreadie ſaid. But at the chaunge, looke what light ſhee received from the Sunne, the ſame ſhee ſendeth all up againe to heaven. Great difference therfore there is in the effects of the moon in both theſe habits, and the ſame very evident and appaL rant: for be it in ſummer, hoteſt ſhe is in the change; but in winter, cold: contrariwiſe, the moon in ſummer being at the full, maketh cold nights, and in winter is warme: the cauſe whereof is plaine and manifeſt. Howbeit, *Fabianus* and the Greeke writers, render another reaſon: for in ſummer time, the moone being in coniunction with the ſunne, and meeting with him when he is in a circle neareſt unto us, muſt of neceſſitie be enflamed with the fire that it receiveth from the ſunne, ſo neare unto her and us both: whereas contrariwiſe, during winter, in the time of the chaunge or conjunction, ſhe cannot chuſe but be cold, as being remote far from us; like as the ſunne alſo, who is retired far South toward the Tropicke of Capricorne. Semblably, at the full in Summer, ſhe is far off from us, as being oppoſite unto the ſunne ſo neare unto us: no marveile therefore if ſhee be cold in regard of our climat: but in winter, at the ſame time of her oppoſiM tion as ſhe is nearer unto us, taking her courſe through the ſummer circle of the ſunne; ſo we may conclude, ſhe doth moderate the rigour of winter cold, and conſequently that then, ordinarily ſhe is warme. Conſidering then that the moone being (at the full in ſummer) ſo cold, and charged ordinarily as ſhee is of her owne nature with much dew, what wonder is it if at ſuch a time

the

A the froſts and dewes that fall bee exceeding cold and congealed againe, which are the cauſe of all the ſaid blaſtings? But above all we muſt remember, that there be two ſorts of accidents comming from above, that mightily doe wrong and annoy the fruits of the earth. The one wee call Tempeſts, which comprehend hailes, ſtormes of wind and raine, and ſuch like impreſſions of the aire, which whenſoever they doe light, are tearmed by the Lawyers, *Vis major*, *i.* the greater violence: and theſe for the moſt part proceed from ſome of the horrible and dreadfull Stars, as we have many times noted, to wit, Arcturus, Orion, and the Kids. Of the ſecond ſort of theſe calamities, be they which happen when the weather is ſtill and quiet without any trouble of winds, in the faireſt and cleareſt nights, and no man ever perceiveth them untill the harme be done: theſe be more publicke and univerſall, theſe differ much from the former; ſome call them Mieldewes, B others Hot-planets; ſome againe tearme them Blaſts and ſindging Carbuncles: but it skills not much what names they have, for all men confeſſe that ſcarſitie and dearth is their effect. And for as much as no man hitherto hath written of theſe Blaſts, &c. I meane to deliver mine opinion of them, and firſt to ſet downe the cauſe and reaſon thereof.

or, the hand of God.

Chap. xxix.

Of the tempeſts and calamities incident to the fruits of the earth, as well in Winter as Summer: the meanes alſo to remedie ſuch accidents cauſing ſterilitie and ſcarſitie.

C THeſe Blaſts, theſe wicked Planets, that ſindge and burne the fruits of the earth, beſides the influence and power of the moone, proceed from other cauſes, and twaine eſpecially, and thoſe are not to bee found in many coaſts and quarters of the heaven: for the ſtarre Vergiliæ, regardeth principally the fruits of the earth, and over them is very predominant; as beeing the only ſtar, which in her riſing and apparition begins ſummer; in her fall and occultation, ſheweth the entrance of winter; by which meanes for ſix moneths ſpace, whiles ſhee is in ſight, ſhee compriſeth harveſt and vintage, and generally cauſeth all fruits to ripen kindly or unkindly.

There is beſides in the heaven, a certain white circle called the Milkeway [or Watling-ſtreet] which is not imaginarie as others, but very conſpicuous and eaſie to be ſeene. By the influence of this circle, as it were out of ſome udder, all plants receive their milke, their humiditie, and nu- D triment, and namely, by the meanes of two notable ſtars obſerved therein; to wit, the Ægle in the North ſide thereof, and the Dog Canicula (whereof we made mention in place convenient) ſituate toward the South. This circle then paſſing through the ſignes of the Zodiacke, Sagittarius and Gemini, and ſtretching by the centre of the Sunne, cutteth the Æquinoctiall line twice in two ſeverall places: the commiſſures or joynts of which two ſignes, are poſſeſſed of the one ſide with the Ægle ſtar, and on the other ſide with the Dog Canicula beforeſaid. No marveile therefore if all countries habitable and fruitfull, be ſubject to the influence of theſe two ſtars and feele their effects; becauſe in thoſe parts onely of the Zodiacke wherein they are placed, the centre and middle of the earth, togither with the centre alſo of the Sunne, agree and meet juſt in one and the ſame point of the Æquinoctiall. Hereupon it is, that if in the ſeverall ſeaſons of theſe E two ſtars aboveſaid, (to wit, when the Ægle and the Dog Canicula, do either riſe or fall, appeare or couch) the aire be pure, cleare, and mild, and thereby the humor genitall diſtilling from that Milkeway or circle aforeſaid downe to the earth, meet with that faire and calme aire, then all plants and fruits of the earth are the better for it, and proſper mightily. Now in caſe the moon either at chaunge or full, doe ſend downe and ſprinkle upon them a cold congealed dew (in maner aboveſaid) the humor and nouriture likewiſe deſcending from the Milke-circle, is infected therewith and becommeth bitter, killing all the fruit upon which it falleth: much like as if a yong babe or infant new borne, ſhould ſucke bitter and unholeſome milke, and thereupon ſoone after die. Thus you ſee, how in every climat whatſoever, the correſpondence of the moone and the ſtars aboveſaid more or leſſe, cauſeth thoſe untoward Blaſts, Mieldewes, and ſuch like; not in like F meaſure at one time and in every place. Which is the cauſe that this kind of injurie and calamitie is not felt at one inſtant throughout the world, no more than the day is one and the ſame in all parts of the earth: for the Ægle (as I have ſaid before) ariſeth to us in Italie thirteen daies before the Calends of Ianuarie, *i.* the 20 of December: now before that day be paſt (by the ordinarie courſe of Nature) there can be no aſſured hope of the fruits of the earth, but that they

may

may miſcarrie: but if it fall out beſides, that the moone upon that day doe chaunge, all fruits as well winter fruits as thoſe which be called Haſtie, muſt of neceſſitie take harme and bee hurt thereby. Rude and ſimple, I confeſſe, were our aunceſtors in old time, and altogither unlettered, howbeit as wittie (as ſhall appeare) in their obſervations and ceremonies, as our Moderns in theſe daies be reſolute, with all their skill they have, grounded upon reaſon and conſequence: for according as they feared three ſeaſons above the reſt, leaſt they ſhould doe harme unto the fruits of the earth; ſo they inſtituted as many Holydaies and ſet feaſts, to wit, Rubigalia, Floralia, and Vinalia. As touching Rubigalia, they were ordained firſt by King *Numa* in the eleventh yeare of his reigne, which now we celebrate a * ſeven-night before May day, to wit, the 25 of Aprill: the reaſon is, for that about this time corne is ſubject to the blaſt. Howbeit, *Varro* following the order obſerved in his daies, ſetteth downe this daungerous time to be, when the Sun is in the tenth degree of Taurus, and occaſioned thereby. But in deed, according to the calcul of others, the true reaſon and cauſe is this, That about nineteen daies after the Spring Æquinox, divers nations have obſerved foure malignant daies, which reach to the 28 of Aprill: in which time, the Dog-ſtar Canis coucheth (a violent and daungerous ſtar of himſelfe by nature) and before which of neceſſitie the other little ſtar Canicula muſt retire and goe downe. And therefore thoſe aunceſtors and forefathers of ours, inſtituted the feaſt of Floralia, as they were adviſed out of the bookes of *Sibylla*, in the 516 yeare after the foundation of Rome cittie: who ordained alſo, that the ſaid feaſt ſhould be held the fourth day before the Calends of May, to wit, the 28 day before-named of Aprill, for this intent, That all plants might blowme kindly, and ſhed their bloſſoms as well. *Varro* ſetteth downe this day to fall out, when as the Sunne is entred fourteene degrees into Taurus. Therefore in caſe it be full moone during theſe foure daies of the feaſt Floralia, not onely corne, but all other plants whatſoever that ſhall bloſſome, are ſure to take great harme thereby. As for the former feaſt called Vinalia, which is kept five daies before, to wit, the * 23 of Aprill, it concerneth nothing at all the fruits of the earth, but was appointed only as a fit time for to taſt wines. And yet for all theſe obſervations before-named, there is none of them pertinent either to Vines or Olive trees, for their time of conception beginneth at the riſing of the ſtar Vergiliæ, to wit, ſix daies before the Ides of May, which is the tenth of that moneth, as we have before declared. About which time, there be other foure daungerous daies, in which husbandmen in no wiſe would have any groſſe and filthie ſtinking dewes to fall, for feare of their Vines and Olives, (for above all, they ſtand in dread of the ſtar Arcturus, which goeth downe the morrow after the riſing of Vergiliæ, and commonly brings with it raw and unkindly rimes) and much leſſe that the moone ſhould happen to be in the full at ſuch a time. The fourth day before the Nones of Iune, which is the ſecond of the ſame moneth, the Ægle ſtarre appeareth the ſecond time in the evening: a judiciall day is this day, and it will go hard with Olives and Vines now in their floure, eſpecially if the full moone alſo light thereupon, and give evidence againſt them. For mine owne part, I would thinke verily, that the Summer Sunſtead ordinarily upon the 25 of Iune is as dangerous; as alſo the riſing of the great Dog-ſtar which alwaies falleth out to be 23 daies after the ſaid Sunſtead, if ſo bee that the moone doe chaunge in any of thoſe two daies; for then commeth the harme by extremitie of heat, which doth ſo bake & harden the young kernels of the grapes and Olives new knit, that they be tanned as it were into a tough calloſitie, that they can thrive and grow no more from that day forward. Againe, the full of the moone is as hurtfull as it, to vines and Olives, if it happen the fourth day before the Nones of Iuly, to wit, the fourth day of the ſaid moneth, at what time the leſſe Dog-ſtar Canicula riſeth to them in Ægypt; or at leaſtwiſe the ſixteenth day before the Calends of Auguſt, which is the ſeventeenth of Iuly, when we in Italy diſcover the riſing of the ſaid Canicula. Likewiſe if the moone chaunce to be in the full betweene the twentie and three and twentie daies of the ſaid Iulie, what time the Ægle ſtar goeth downe, the ſame daunger befalleth vines and Olives. As touching the ſecond feaſt Vinalia, which is obſerved and kept thirteene daies before September, to wit, the 20 of Auguſt, it is not to be raunged among theſe, as being of another nature, and inſtituted at firſt for other cauſes. *Varro* would have this feaſt to begin at the departure of the Harpe-ſtar Fidicula, which beginneth to retire in the morning, and which day he ſetteth downe for the firſt entrie of Autumne: ſaying moreover, that this feaſt was inſtituted for appeaſing the ſtormes and tempeſts incident to that ſeaſon. And now obſerved it is, that the ſaid Harpe-ſtarre Fidicula ſetteth ſix daies before the Ides of Auguſt, which is the eighth day of that month. Thus much

* S. *Marks* day with us.

* S. *Georges* day with us.

G H I K L M

A much as touching the cauſes of ſterilitie and dearth, occaſioned by the conſtellations, according to ſundrie ſeaſons of the yeere, after that calculation which I goe by: But I will not bind every man thereto, for well I know and cannot denie, but the readers may chaunge and alter the ſame at their pleaſures, according to the diverſitie of the climats; in regard whereof, the obſervation alſo of thoſe daungerous daies may vary from mine account. For this preſent, it ſufficeth my turne that I have ſet downe the true cauſe in Nature, from whence proceed thoſe calamities: all the reſt beſides, I refer to ech mans conſideration, who for any thing that I have ſaid, may take their libertie and obſerve what they think good. Certes this ſhall be found cleare and doubtleſſe in the end, That theſe unkind dews and dangerous blaſts are occaſioned by one of theſe two cauſes, to wit, either the full or chaunge of the Moone. And herein verily, I cannot chuſe but me-
B ditate upon and admire the wonderfull goodneſſe and bountie of dame Nature; firſt in this, That ſhe hath ſo limited and determined the ſet courſe of the ſtars, that theſe calamities cannot poſſibly happen every yeare; neither yet oftentimes in the ſame yeare, but onely ſome few nights, to wit, in the chaunge or full of the Moone: and when they will come, it is eaſie to foreknow and fore-tell. And to the end that we ſhould not need to feare theſe daungers every moneth, ſhee hath ſo ordered the matter, and divided the influence of the Moone by night in ſuch ſort, that ſetting aſide two daies in Summer, the chaunges of the Moon do no harme at all: no more than the full in Winter: neither are theſe two new Moones to bee feared, but in Summer nights, and thoſe ſhorteſt of all other, wherby they have leſſe time and leaſure to offend the earth: for all the day long they have not the ſame force, nor work the like effects. Over and beſides, ſo eaſie a mat-
C ter ſhee would have it for to know either the conjunction or oppoſition of the Moone, that the very Piſmire (the ſillieſt and leaſt creature of all other) by inſtinct of Nature, is our guide to the one and the other: for in the chaunge ſhe is ſeene commonly to reſt and take her repoſe; whereas at the full Moone ſhe workes and labours both night and day. And that we ſhould not bee ignorant of the Dogge-ſtar Sirius his riſing, looke what day he ſheweth firſt, the little Nonett or bird, called in Latine Parra, goeth aſide, and appeareth not again before he be hidden and gone downe. Contrariwiſe, the Loriot, Greene-finch, or Canarie bird Vireo, commeth abroad the very day of the Summers Sunneſtead, and not before, that we ſhould not pretend ignorance of the longeſt day in the yeare, a time whereon dependeth ſo great a conſequence. But be it change or be it full, neither the one nor the other habite of the Moone is daungerous, no not in the ve-
D ry night ſeaſon, unleſſe it be cleare and calme, that is to ſay, faire ſtar light, and all winds laid: for neither in cloudie and cloſe weather, ne yet when the winds are aloft, doe any dewes fall. And at ſuch times alſo as they uſe to come, there is a remedie provided againſt them: for when thou feareſt a blaſt or Mieldeaw, lay me altogether all over the fields and Vineyards (by heaps) Vine-cuttings and ſuch drie ſtickes, chaffe, ſtraw, and other like mullocke, drie weeds & ſhrubs which have been plucked out of the ground, and ſet them all on fire; the very ſmoke will helpe this matter, and avert the daunger from corne and grapes. And as for the fume of chaffe and ſtraw, it is good againſt ſtinking fogs and miſts, when they are thought to doe harme. Some there bee that preſcribe to take three Crab-fiſhes alive, and to burne them in Hortyards among the trees, to preſerve and defend them againſt the ſendging blaſt called the Carbuncle. Others take the fleſh of
E the fiſh Silurus, & roſt or broile it ſoftly upon the fire, on the wind ſide, to the end, that the fume and ſmoke thereof might be caried and diſperſed all over the Vineyard, to chaſe away the ſcorching blaſt aforeſaid. *Varro* affirmeth, That if about the retrait of the Harpe-ſtar Fidicula, which is the beginning of Autumne, a man paint a cluſter of grapes, and conſecrate it to the gods among the Vines, the ſtormes and tempeſts of wind and raine will do leſſe harme to the fruit hanging thereupon. *Archibius* in a booke that hee wrote to king *Antiochus*, ſaith, That if a land-toad be put into a new earthen pot that never was occupied before, & the ſame enterred and covered within the ground in the middeſt of a corne field, the corne ſhall take no harme that yeare by any tempeſts whatſoever.

As touching the ruſticall worke which ſhould be done in theſe ſix weekes ſpace, the Husband-
F man ought to give his lands a ſecond fallow, to dig about the roots of trees, and (where the heat of the countrey doth ſo require) to mould and banke them againe: howbeit, ſuch as be budding and putting forth new ſhoots, would not be digged, unleſſe the ſoile be very good and ranke. Seminaries or nource-gardens would now be ſarcled and cleanſed. Addreſſe himſelfe he muſt, and make all readie againſt Barley harveſt. Now is he to prepare his barne plot and thraſhing floore,

and to pave it with a coat of chalke, tempered well and wrought with oile dregs, by *Catoes* advise; howsoever *Virgil* is more curious in this behalfe. For the most part of Husbandmen, after they have laid it even and levell, they goe over it againe with Oxe dung, tempered to a thin consistence with water, for to bind the said floore: and this is thought to bee a sufficient remedie, that the dust shall not rise.

Chap. xxx.

Of Corne-harvest: of common Wheat: of Chaffe: and the order how to keepe corne.

As touching the manner of cutting downe or reaping corne, there be diverse and sundry devises. In Fraunce where the fields be large, they use to set a jade or an asse unto the taile of F a mightie great wheelebarrow or cart made in manner of a Van, and the same set with keene and trenchant teeth sticking out on both sides: now is this carre driven forward before the said beast upon two wheeles, into the standing ripe corne (contrarie to the manner of other carts that are drawne after) the said teeth or sharpe tines fastened to the sides of the wheelebarrow or car aforesaid, catch hold of the corne eares, and cut them off: yet so, as they fall presently into the bodie of the wheelebarrow. In some places the fashion is to cut with a hooke or sycle the straw in the middest: and betweene every two sheaves they sit downe, and then crop off the eares just at the straw. In other countries they use to plucke up the standing corne by the root: and in so doing, perswaded they are that this is a very neare and readie way to save charges, & may serve for one tilth well ynough: but by their leave, they rob the ground by the meanes of her kind and I naturall moisture. The reason of this diversitie and difference is this: in such countries where they use to thatch their houses with straw, they save it to the full length, and goe as neare as possibly they can: againe, where there is but small store of hay, they make account of their short chaffe for to litter, yea, and fodder their beasts. As for Panicke haulme, it never serveth the turne in any place for thatch. And for Millet straw, they burne it ordinarily. Barley straw is kept and saved very carefully for an excellent fodder, that kine and oxen love very well. To conclude, in France they have another way to gather their Panicke and Millet especially, to wit, cutting the same eare by eare upon a combe with a handle to it [as Barbers use to clip or poll mens heads.]

Concerning the devise of thrashing, it is practised sundrie waies. In some places they use to crush the corne out of the eares with heavie and rugged dreies drawne over it, as it lieth upon K the barne floore. In others, they set Mares to stampe and trample it under their feet, and so drive it out: and there be againe who beat and flap it forth with flailes or cudgels.

Common wheat, the later that it is reaped, the better it is found of cast: but the sooner that it goeth downe, the fairer is the graine, and more full and weightie. The best rule for the one and the other, is this, to goe downe with it, and lay it along, before the corne bee verie hard, and when it begins once to looke russet, and to have a browne or reddish blee. And here, remember the old said Saw that may goe well for an Oracle, Better two daies too soone, than as many too late.

For the inning of the fine wheat Siligo, and the common Triticum, it is much after one sort, L and they would be ordered alike, both in barne, rike, and thrashing floore. The good red bearded wheat Far, because it commeth hardly out of the huske, and asketh some painefull thrashing, ought to bee laid up in the garner, huske and all together, even in the chaffe; onely it would be rid from the maine straw, and despoiled of the eiles or beard growing to the eare. Chaffe is good chaffre in many countries, and serves in stead of hay. Where note, that the finer and smaller that the chaffe is, and enclining nearer to pouder, the better it is thought to be. And therefore the best simply is that which commeth of Millet: the next in goodnesse, Barley maketh: but the common wheat Triticum yeeldeth the worst, unlesse it bee for poore hungrie jades and such labouring garrons.

The straw or haulme that remaineth standing as boltings when corne is reaped by the eare or M after it be well dried, the manner is to lay upon some hard, craggie, and stonie ground, then all to beat and belabour it with cudgels, that it may bee soft and serve in stead of litter to lie under cattell. If chaffe faile for fodder, the very haulme or straw left in the field, ought to bee braied and beaten short, to supplie forrage in manner following. Cut it downe so much the sooner, let it bee

well

A well ſprinckled and drenched a long time in brine: and when it is dried againe, make it up round into certaine bottles or bals, and ſo give it to kine and oxen for their fodder. There bee that ſet fire on it, and ſtraw both, in the field whereas it grew. And ſurely, *Virgil* highly commendeth this for a great point of Husbandrie: the cheefe reaſon hereof was, to burne the ſeed that the weeds ſhed, and to kill their roots that remaine upon arable ground. In ſumme, the diverſe faſhions and manners of reaping, proceed from this, That in ſome countries the harveſts bee greater than in others: and beſides, Reapers and mowiers are not to bee had in all places alike, nor ſo eaſily hired.

It followeth now by good order, as a matter hereunto annexed, to write of the manner how to lay up and keepe corne for ſtore. Some are very curious and indeed over preciſe in this point,
B and namely in building of barnes and garners. For they give order, that in any wiſe their walls be raiſed of bricke, and thoſe three foot in thickneſſe. Alſo, that they be filled top full and cloſed up aloft, that they have no windows at all, nor any place open to let in or admit wind. Others would have windowes, but thoſe onely toward the Northeaſt wind, where the Sunne riſeth in Summer, or elſe into the North: and in any hand the bricke muſt not bee laid with lime, for that it is moſt hurtfull to corne. For as touching oile dregs or lees, how they would have it to bee uſed, I have declared alreadie. Contrariwiſe, in ſome countries they build their garners of timber, and ſet them aloft in the aire hollow from the ground, bearing upon piles and poſts of wood: and ſuch are deviſed of purpoſe with many ouvertures on every ſide to receive wind, inſomuch, as from beneath alſo the bourds and plankes bee open to take all aire. And yet others
C there bee who miſlike altogether theſe kind of frames, being of this opinion, That in ſuch ſolars and lofts reared ſo high into the aire, the corne will diminiſh and wither: yea, and if it lie neare to a roufe of tiles, it will bee in daunger to catch a fire and burne. There bee that would not have corne to bee turned in the garner, for to breath and take the wind: for that the mite or weevill that eateth graine, never commeth within foure fingers of the bottome of the heape, ſo that beneath that gage there is no danger, and therefore it needs no ſuch ſtirring at all. *Columella* ſaith, That it were good to have a garner open into the Weſt, for that the wind Favonius is kind for corne: whereat I marvaile very much, conſidering that otherwiſe he is carefull to ſeeke out the drieſt places. Laſt of all, there be ſome that would have a land-toad tied by one of her hinder or longer legges, and ſo to hang at the dore and entrie of the garner or barne where
D corne lieth. For mine owne part, if I ſhould ſpeake what I thinke, I hold, that the cheefe and principall thing for the keeping of corne well, is to know and uſe the verie fit time and ſeaſon of laying it up. For if it bee gathered when it is not fully ripe, and before it have the due parching from the Sunne, and the firme ſubſtance hardened as it ought, likewiſe if it bee brought unto the barne or garner hote, it cannot bee avoided, but vermine will breed therein to doe it much hurt.

That ſome kind of graine will continue good and ſound, yea, and laſt longer than other, there bee many cauſes. For either it proceedeth from the skin or huske, when it is manifold, as in Millet; or the fatneſſe of the marrow and floure within, which maintaineth and feedeth the graine as the radicall and nutritive humour, as in Seſama; or laſtly, of bitterneſſe, as in Lupines
E and the ſmall bitter Cichets. As for the Frument or wheat Triticum, apt it is moſt of all other to engender and breed weevils and ſuch like wormes, becauſe it ſoone catcheth a heate, and is quickly enchaufed, by reaſon of the thicke and faſt ſubſtance of the owne, and beſides encloſed and clad it is within a thicke and groſſe skin, which is the bran. Barley hath a finer and ſlenderer huske: and ſome Pulſe a thinner than it: ſuch therfore are not ſubject to the ſaid vermine. Howbeit, Beanes bee covered with thicke pillings or tunicles, and therefore eaſie to take an unnaturall heat and putrifie. Some uſe a deviſe to keepe Frument corne a long time, with oile lees, beſtowing onely the ſprinckle of one Quadrantall, to a thouſand Modij thereof. Others beſtrew among it the pouder of Chalke brought either from Chalcis or Caria; or elſe lay ſome
F Wormewood among it. There is a kind of earth in Olynthus and Cerynthus within Eubœa, which is highly commended in this caſe, for it will not ſuffer corne to corrupt. And lightly, what corne ſoever it be that is laid up in the eare, never taketh any harme, keepe it as long as you will. Howbeit, the beſt and moſt aſſured way to preſerve corne, is in caves or vaults under the ground, which in Latine be called Siri, as the practiſe is in Cappadocia and Thracia. In Ægypt and Barbarie, above all things they looke to this, That their garners ſtand upon a drie ground:

and how drie ſoever the floore be, yet they lay a courſe of chaffe nnderneath betweene it and the corne. Moreover, they put up their corne in garners and bins, togither with their ſpike or eare: by which deviſe they are ſure (if no aire come in) that no hurtfull worme or vermine will breed among it. And verely *Varro* ſaith for certein, That wheat in that manner laid up, will laſt fiftie yeeres, and Millet an hundred. Hee affirmeth moreover, that beans and other pulſe will keepe good a long time in oile barrels, if they bee calked with aſhes. Hee avoucheth moreover, that beans were knowne to have continued from the time wherein king *Pyrrhus* lived, unto the Pyrats warre, which under the conduct of *Pompey* the Great was diſpatched and brought to an end; which proviſion of beans had been laid up 120 yeares before, and kept cloſe in a certaine cave under the ground, within the cittie of Ambracia. The Cich peaſe is the only graine that is ſubject to no vermin breeding in it while it lyeth in garner or barne. Some there are who take certeine pitchers of earth having vinegre in them, upon which beeing well bedded in aſhes and done over with pitch, they make their heaps of pulſe, and by this meanes they are verily perſuaded, that no meevils, mites, or other wormes will breed therein to doe harme. Others, for to preſerve their pulſe, put them into ſalt-fiſh barrels, but they dawbe the ſame firſt with a certain kind of mortar made of plaſtre. Laſt of all, for to keepe Lentils, there be that drench them with the vinegre confected with Laſerpitium, and when they bee dried againe beſmeare them over with oile. But will you have indeed one ſhort rule for all? To be ſure that no worme or vermin ſhall breed in your corne, cut it downe and gather it about the chaunge of the moone. Therefore it skilleth very much to know a mans intention, whether hee meane to keepe or to ſell his corne: for certein it is, that as the moone groweth, ſo doth corne wax full and great, and therefore filleth the ſtrike a great deale better.

Chap. xxxi.

Of Vintage: and the particular ſeaſons in Autumne.

According to our partition of the yeare into four quarters, it followeth now by courſe and order, to treat of the Autumne, which beginneth at the retreat or occultation of the Harp-ſtar Fidicula; and ſo forward to the Æquinox in September: from whence I will proceed to the couching or going down of the Brood-hen Vergiliæ, the very beginning & firſt entrance of the winter. In which meane ſpaces and equall diſtances, both before & after the ſaid Æquinox, theſe ſtars following are ſignificant, and ſet out the particular ſeaſons: Firſt, the day before the Ides of Auguſt, [*i.* the twelfth of the month] the ſtar called the Horſe, appeareth in the Hæmiſphære to the people of Attica: but at eventide the ſame day, the Dolphin ſtar ſetteth to them in Ægypt, and likewiſe to us here in Italy, according to *Cæſars* account. Alſo eleven daies before the Calends of September, which is the 22 day of Auguſt, (by the calculation of *Cæſar* and the Chaldæans) the ſtar named in Latine * Vindemiator, *i.* the Vintager, beginneth to ſhew in the morning, both to the Aſſyrians and the Italians; a truſtie vaunt-curriour, bringing certaine tidings with him, and promiſing aſſured hope of a vintage, and that the grapes will be ripe anon: and for a farther token and apparence thereof, marke the grapes then, for now begin they to chaunge colour. To the people of Aſſyria, the fifth day before the Calends of September, *id eſt*, the 28 of Auguſt, both the ſtar Sagitta ſeemeth to goe downe, and withall the Eteſian winds lie, and give over blowing. The Vintager himſelfe, to wit, the ſtar ſo called, to the inhabitants of Ægypt riſeth upon the Nones of September, *i.* the fifth day of the month: upon which day to the people of Attica, the ſtar Arcturus riſeth in the morning; and the Sagitta, *i.* the Shaft, goeth downe in the evening. To come now to the Ides of September: five daies before them, that is to ſay, the ninth day of the moneth (after *Cæſars* card) the ſtar called Capella, *i.* the Kid, ſheweth it ſelfe here in Italy toward evening: but the day before the ſaid Ides, *i.* the twelfth day of the moneth, the one halfe of Arcturus appeareth to riſe: and then for five daies togither (his influence is ſuch) he keepeth ſuch foule worke both by ſea and land, that both Sailer and Husbandman feele the violence of his arrivall: and this reaſon is given therof; For if (ſay they) at the fall or occultation of the Dolphin ſtar, there be no ſhowres of raine, none will Arcturus bring with him at his comming. An evident ſigne there is, that the ſtar Arcturus will not be long before he ariſe, and that is this, The departure of the Swallowes: for this is certein, if hee chaunce to ſurpriſe any of them, and that they be not gone before out of the countrey, they are ſure to pay for their

* rather, *Provindemiator*, *i.* the forerunner of the vintage, προτρυγητὴρ: for *Vindemiator* followeth afterward in September.

A their long tarrying and to die for it. The ſixteenth day before the Calends of October, which is the ſixteenth day of September, the ſtar called Spica, *i.* the Eare of corne, which the ſigne Virgo (*i.* the Virgin) holdeth in her hand, riſeth in the morning to them in Ægypt; and then the Eteſian winds alſo are quiet and laid in that countrey. Howbeit after *Cæſars* calculation, this falleth out upon the fourteenth day before the Calends of October, *i.* the 18 of September, to us in Italy: and by the account of the Chaldæans, a day after to them that dwell in Aſſyria. Moreover, the 21 of September (after the ſupputation of *Cæſar*) the Knot of the two fiſhes, a ſigne or ſtar ſo called, goeth downe to our ſight in Italie; like as the very Æquinoctiall ſtar it ſelfe three daies after. After which time, *Philippus*, *Calippus*, *Doſitheus*, *Parmeniſcus*, *Conon*, *Criton*, *Democritus*, *Eudoxus*, and *Ion*, agree all in this, (and that is marveile to ſee ſo many Aſtrologers to accord)

B That foure daies before the Calends of October, the ſtar Capella, *i.* the Kid, riſeth in the morning: and the morrow after, the [two] Kids doe the like. The ſixt day before the Nones of October, which is the ſecond day of the moneth, in Attica and the regions adjoyning, the ſtar named the Crowne appeareth betimes in the morning: but in Aſia, and to us Italians (after the reckoning of *Cæſar*) the next day following, the ſtar Heniochus goeth downe in the morning. Two daies after that, to wit, the fifth of October (according to *Cæſars* computation) the ſtar named Corona, *i.* the Crowne, beginneth to ſhine in Italie: the next day after, the ſtars called the Kids, looſe their light in the evening. The eighth day of October, which is eight daies before the Ides thereof, the ſhining ſtar within the foreſaid Corona, ſheweth it ſelfe in Italie, by *Cæſars* booke: but the 13 day of the ſame moneth, the ſtar Vergiliæ, *i.* the Brood-hen, ſheweth in the evening:

C and vpon the very Ides, which is the 15 day of the moneth, the Crowne ſtar aforeſaid appeareth full and whole. Now ſix daies before the Calends of November, *i.* the 27 of October, the ſtars called Suculæ, or the rainie Hyades, begin to ſhew in the evening: and the laſt day of October, which is the even of the Calends of November, (if *Cæſar* ſay true) Arcturus ſetteth in Italy, and the ſaid Suculæ or Hyades riſe the ſame day togither with the Sunne. Foure daies before the Nones of November, *i.* the ſecond day of the moneth, Arcturus goeth downe in the evening: like as the fift day before the Ides, *i.* the ninth day of November, the ſtar named Orions ſword beginneth to retire: and likewiſe two daies after, the Brood-hen Vergiliæ is hidden and appeareth no more.

As touching now the countrey worke that Husbandmen are to employ themſelves about du-

D ring this ſpace of time or halfe quarter thus deſcribed, they ought if they did well, to ſow Navewes, Turneps, and Radiſhes, upon thoſe daies that I have appointed heretofore: and let them never goe by the voice of the rurall ſort, who thinke it not good to ſow ſo much as Rapes, after the departure of the Storke: for bold may we be here in Italy, even after the feaſt Vulcanalia to put them into the ground; as alſo our early white corne, togither with Panicke. But after the going downe of the Harpe-ſtar, good I hold it to ſow Vetches, Phaſeols, or Kidney-beans; as alſo the dradge or bollemong for horſes, called Pabulum, *i.* Forage: howbeit, folke ſay, that this forage would not be ſowne but about the new moone. This is the time alſo to ſtrip green leaves, and ſlip tendrons from trees, thereof to make fodder for beaſts in winter: and one good daies worke it is for a man to fill foure hampers made of purpoſe for ſuch brouſe, Now if theſe leaves

E be gathered and prepared before-hand when the moone is in the wane, they will never corrupt and putrifie. Greene muſt this brouſe be in any wiſe when it is gathered, and not ſeere or withered.

To come now unto Vintage: men thought in old time that it was not readie nor the grapes ripe enough, before the Æquinox in September: but now adaies I ſee how they goe to worke every where ſooner, and fall haſtily to gather grapes halfe ripe. Therefore it were not amiſſe to ſet downe certaine markes and ſignes to direct the husbandman for this ſeaſon. The rules therefore to guide him, be theſe: Gather no grapes hot, that is to ſay, when they be drie, nor unleſſe a good ſhowre of raine come betweene: yet take heed you muſt, that you plucke them not full of dew, namely while the dew that fell over night, doth ſtand upon them; nor before the Sun hath

F drunke up the ſaid moiſture, and dried them. Set into thy vintage hardly and fall to gathering, when either the vine leaves or greene braunches called the Portoirs, doe fall and reſt upon the old wood: or when, after you have taken one grape from the reſt of his fellowes ſtanding thicke togither in the cluſter, you ſee the void place not to fill up againe, whereby it appeareth that the grapes and kernels about it, grow no more. Very good it is for grapes, if they be gathered when

the moone is croiſſant, to wit, before the full. At one preſſing ordinarily, there ſhould be filled twentie meaſures called Culei, *i.* Cowles: now is this meaſure for liquors the greateſt of all others, and by which the reſt ought to be proportioned juſtly. For to preſſe thus many cowles at once, and to ſerve twentie acres of vineyard, one wine-preſſe is ſufficient; and likewiſe to hold the ſame, one veſſell or keelvat. Some uſe but one planke or ſtocke to preſſe withall, but better it is to have them double: although thoſe that be ſingle be exceeding huge. As touching theſe preſſing plankes, it is not ſo much their thickneſſe and maſſive ſubſtance that is to be regarded, as their length; for in deed the longer and larger they bee, the better they doe their deed. In old time they uſed ropes, leather thongs, and leavers, and by force of them pulled downe and forced hard the preſſe-planks. Within this hundred yeares were the frames deviſed which wee call Græcanica; wherein the maine planke or upper ſtocke of the preſſe, went with a vice in manner of a skrew; for the wrinkles of the ſpindle were fitted and ſerved in an engin or windlace in manner and forme of a ſtar, ſet faſt to the worme or vice of the ſpindle aforeſaid, and which as it was turned and wreſted, lifted up or let downe the preſſe-planke or lid, togither with the weights of ſtones thereupon: and verely this faſhion of preſſes was held to bee beſt and moſt approoved. Howbeit, it is not 22 yeares ſince there came up another deviſe and invention to make ſmall preſſe-planks; leſſe winding peeces alſo, and the whole frame ſhorter: howbeit in the mids ther-of ſtood up the ſpindle of the ſaid skrew or vice. Now when they purpoſed to ſquize out the grapes, they laid certain lids or planks thereupon called Tympana, and thoſe they forced with a wreſt from aloft, uſing alſo the poiſe and weight of ſuch matters as they heaped upon the planks aforeſaid.

* *Culeus* containeth 20 Amphors, which is 320 *Congij* or gallons.

Moreover, the cuſtome is to gather apples and ſuch like ſoft fruit, about this time, with this obſervation or direction, namely, To go in hand with this buſineſſe when any are ſeene to fall of themſelves, as mellow and ripe, and not blowne downe by force of wind and tempeſt. Now is the ſeaſon alſo to preſſe out the lees or ſediment of the grapes: now the time ſerveth to ſeeth new wine to the halfe, and make cuit thereof; with this regard and conſideration, that if the moon be upon the chaunge, this be done by night; but if in the full, by day-light. As for other daies, it matters not much, ſo that the cuit be boiled either before the moone riſe, or after ſhe be gone downe. Moreover, heed is to be taken, that the grapes of yong vines or ſuch as grow upon low and mariſh grounds, be not uſed hereabout; and much leſſe thoſe that be not fully ripe. In the ſcumming alſo and clarifying of the liquor while it boileth, no other thing but leaves are meet for that purpoſe: for if any wood come neare and touch the veſſell or lead wherein the liquor is ſodden, it is thought that the cuit will be ſmoakie and ſmell of the fire. Furthermore, the ordinarie time of vintage holdeth 44 daies, to wit, from the Æquinoctiall in September, unto the going downe or occultation of the Brood-hen Vergiliæ: after which time, remember the oracle and common proverbe, That wine veſſels are not to be roſined, calked, and trimmed in cold; for good husbands would do this before-hand in hot weather. Howbeit in theſe daies I have ſeen thoſe that for want of veſſels have gone in hand to tun up their wine in the beginning of * Ianuarie: yea I have knowne when the vintage hath been ſo great, that wines newly preſſed have been kept in fiſh ceſterns: and for default of other pipes and tuns, when the wine-cellars have been full alreadie, I have ſeen them that would let the old run out into ſuch ceſterns, for to make room for the new, and ſuch as a man would ſay were neither made nor unmade. And yet this is not ſo often practiſed by occaſion of the exceeding ſtore of new wine that lyeth upon mens hands, as of a wicked and covetous mind that ſome carie to gather a deale togither for to ſet up a monopolie, thinking thereby to make a dearth and to raiſe the price of their wines, to the great detriment and hinderance of a common-weale. But a good and honeſt minded houſholder will reſt contented to furniſh himſelfe with a competent proviſion of wine, and lay up no more than he ſhall ſpend every year: and this is found alſo by experience the moſt profitable way for his purſe. As for all other matters concerning wine, becauſe I have alreadie ſpoken at large thereof, I will here lay a ſtraw and make an end. But this would not be forgotten, that ſo ſoone as grapes be gathered, men muſt high them apace and make haſt to get in their Olives: for preſently after vintage and wine-preſſing, they muſt thinke of drawing their oile, and employ themſelves in other workes of this ſeaſon, which are to bee done a little before and after the retreat of the Brood-hen ſtar Vergiliæ.

* Some read, November.

Chap. xxxii.

The conſideration of the Moone and her courſe, reſpective unto Husbandrie.

HEreunto ſhall bee annexed a diſcourſe as touching the Moone and the Winds, together with the Prognoſtication depending thereupon, as much as may bee thought neceſſarie and pertinent to Agriculture; to the end, that our ruſticke Aſtrologie may in all points be accompliſhed and perfect. For *Virgil* alſo was of this opinion, That ſome buſineſſe and workes of Husbandrie were to be digeſted and divided juſt according to the daies of every Moon in or-
B der as they goe, following herein the vanitie and oſtentation of *Democritus*. For mine owne part as I have hitherto in all my worke throughout reſted upon the good and profitable rules of our auncestors, ſo in this point alſo I meane to take their direction, and goe by no other. According to their ordinances and precepts therefore, this firſt is to be obſerved, That whatſoever is to bee cc
cut, gathered, or laid up, be it wood, fruict, or graine, it ought to be done rather in the wane of the cc
Moone, than whiles ſhe is croiſant toward the full, & leſſe daunger is it ſubject unto. *Item*, Touch cc
no mucke, nor lay it upon thy lands but after the full, when ſhee is in the wane. *Item*, Dung thy cc
ground, whiles the Moone is in conjunction with the Sunne, and in the firſt or laſt quarter. Gueld cc
Bores and Steeres, lib Rams and Kids or young Goats in the old moone. *Item*, Set Hens to couve cc
egs in the new of the Moone. Make thy trenches by night in the full Moone. Likewiſe, cover the cc
C roots of trees with mould when the Moone is at the full. *Item*, In moiſt grounds ſow and ſet either cc
in the very chaunge, or foure daies before and after. As for the winnowing, vanning, and laying cc
up either of corne or pulſe, they would have it done in the old Moone, about the laſt quarter. As cc
alſo, That Pepiniers, Seminaries or Nource-gardens, be made when the Moon appeareth above cc
the earth. But grapes ought to be troden, and new wine preſſed, whiles ſhee is under our horizon. cc
Likewiſe, timber is to bee hewed, and many things elſe to bee done accordingly, whereof wee have written alreadie in their ſeverall places. And albeit the obſervation of the Moone, her age and chaunge is eaſie ynough, and nothing more familiar: whereof alſo I have written ſufficiently in the ſecond volume of this worke: yet further to inſtruct the ſimple countreyman who knoweth never a letter of his booke, and to ſet before his eies the true order and courſe of her moti-
D on and mutation, let him but obſerve and marke thus much, That ſo often as ſhe is ſeene Weſtward after the Sunne is gone downe, and ſhineth the forepart of the night onely, ſhe is croiſant, and in her firſt quarter, and then ſhall a man diſcerne evidently by the eie the one halfe of her bodie light: but looke when, as the Sunne ſetteth in the Weſt, ſhe riſeth at the ſame inſtant over-againſt him in the Eaſt, ſo as they may be both ſeene at once, be ſure ſhe is in the full. Againe, whenſoever ſhee riſeth late in the Weſt, and ſhineth not in the fore-part of the night, but toward the morning, make account ſhee is in the wane, and ſheweth but her halfe part againe. But ſo long as ſhee appeareth not at all, and giveth no light, aſſure your ſelfe ſhee is in the conjunction with the Sunne all that while, and this in Latine is called Interlunium, [i. the change.] Now at the verie inſtant of her conjunction or chaunge, and the firſt day, untill ſhe bee one day
E old, ſhee will remaine above the earth ſo long as the Sunne is there alſo with her: the ſecond day ſhe will bee in our hemiſphære by night, tenne * twelve parts of an houre, and a quarter of one * 51 minutes & 1/2.
twelfth part. Thus in proportion will ſhee riſe unto the fifteenth day after her chaunge, multiplying everie day the ſaid portion of the houres. When this fifteenth day is come, ſhee will be all the night whole above the earth, and all day long under. Vpon the ſixteenth day of her age ſhee will remaine beneath our Hemiſphære, after the firſt day, tenne parts of twelve, and one quarter of a twelfth part within night before ſhee riſe and ſhew her ſelfe, and ſo will ſhee keepe daily the foreſaid proportion juſt, in late riſing: deminiſhing ſtill her light by the ſame degrees, untill the chaunge. And looke how much ſhee ſtaieth in the beginning of the night under the earth ere ſhee appeare in our Horizon, ſo long in the next morning will it bee after day-light,
F ere ſhee goe downe. Finally, every ſecond moneth the Moone hath thirtie daies full out: like as each other moneth betweene ſhee wanteth one of that number, and hath but nine and twentie. Thus much concerning the courſe of the Moone in regard of Husbandrie.

Chap.

G

Chap. xxxiii.

The consideration of the Winds, respective to Agriculture.

As touching winds, the reason and quartering of them is more intricate, fuller also of scrupulous doubts and difficulties, than was the observation of the Moone: notwithstanding that, there is not a day in the yeare goeth over our head, but wee may easily find and marke both South and North. For if a man doe observe the Sunne rising any day whensoever hee will, and upon the sixt houre of the same day (to wit at noone) stand so as he have his left shoulder directly turned against the said Sunne rising, he may be assured, that hee hath the South full upon his face, or before him, and the North behind his backe. Now the line or streight way that runneth in this manner through a field North and South, is called in Latine *Cardo. When a man standeth thus, if he would see his owne shaddow, he shall doe well to turn his bodie round about: for otherwise it will be behind him. Chaunging sides therefore, so as he have the Sunne rising or Levant of that day just against his right shoulder, and the setting upon his left, hee may know the mid day or South point as well as before, namely, when his bodie casteth just before him the shortest shaddow, enclining to the one hand no more than to the other. Let there bee then either a small furrow rased along just through the middest of the shaddow with a spittle spade, or the point of some hooke; or else a line drawne with a traine of ashes, for the length of some twentie foot or thereabout (to make the thing more plaine.) Which done, cut the said line or furrow crosse overthwart the middle, to wit, at the tenth foot, if the whole bee twentie: and then make a round small circle about it, which may serve in steed of a Navill, and bee so called. That part of the line then which goeth directly forward from the crown of the head in the foresaid shaddow, pointeth out the North wind. Thou therefore that art to lop or prune trees, take heed thou makest not thy cuts so, as they looke into that coast: neither let thine hortyards or vineyards stand open to that wind, unlesse it be in Affricke, Cyrene, and Ægypt. Againe, so long as the wind sits in that corner beware Ploughman [for now I speake to thee] thou breake up or eare no ground, nor enter into any such worke in the field as thou art alreadie forbidden by mee to doe. But marke what part of the line shall come from the foresaid Circle straight before thy feet, regarding the noone-tide or mid-day, assure thy selfe the same telleth thee which is the South wind, called by the Greekes Notus, as we have declared alreadie. Doth the wind rise and blow from that side? meddle not Husbandman during that time with thy vine. Carpenter, fell no trees then for timber I advise thee. A wet wind this is and hote, within the climate of Italie. In Affricke verily drie ynough it is, and bringeth faire weather with it, but with all his faire looks, he kindleth fire otherwhiles, and burneth many things. Let hardly the Vine spread her braunches, and run into this wind, in all places of Italie: but leave not the cuts either of tree or vine looking that way. He that setteth out a plot of ground for Olives, and planteth them, hath cause to bee afraid of this wind, especially for foure daies together, about the rising or apparition of the star Vergiliæ or Brood-hen. They also that graffe tions in the stocke by cleft, or set bud in the scutcheon by way of inoculation, must take heed how they meddle in this wind.

*Vitruuius & citratus veteribus

I

K

Moreover, it will not be amisse to give some caveat as touching the very houre of the noone-day, which giveth us knowledge of this wind and this quarter; namely, what is to be done at such a time, and what not? Thou woodman and forrager both, see thou neither cut nor lop trees, see thou gather no greene leaves and tendrils for thy fodder at noone-tide. Thou sheepeheard, thou heardman whatsoever, when thou perceivest in Summer time by thy shaddow growing short, that noonestead is at hand, drive thy sheepe and cattaile out of the Sunne, into some worme-stall and place of shade. More yet I have to say to thee, If thou keepe sheepe or other beasts at their pasture in Summer time, lead them or drive them before thee all the morning into the West, before mid-day; but after noone turne thy face Eastward with thy flocke and thy heard. Otherwise, and at other seasons, as namely, all Winter and in the Spring, thou shouldest doe thy cattaile hurt, to conduct or lead them after this manner out of the warme Sunne into moist places, and where the dew faileth. As charie also and heedfull must thou be to drive thy cattaile Northward from the Sunne, and there to let them graze: for marke what I say, In so doing, they will not bee able to hold open their eies; this wind will make them bleared & bloudshotten; nay, it will drive them into a gurrie or flux of the bellie, which will soone make an end of them. Howbeit, if thou wouldest

L

M

A wouldeſt have the beaſts conceive and bring forth females, force them when they be leaped and covered, to ſtand with their heads into this wind, and thou ſhalt ſee the proofe hereof.

Chap. xxxiiii.

Of the lines and limits that divide and bound fields.

WEe have ſhewed in the next chapter before, the manner how to draw a line or furrow North & South; and how in the midſt therof there ſhould be a round compaſſe, made manner of a Navill, which in Latine is called Vmbilicus. Now if you would know likewiſe the other parts of the heaven, let there run ſuch another line overthwart the Navill or Cir-
B cle juſt in the middeſt: and then ſhalt thou ſee, that this line will direct thee to the Eaſt and Weſt points, Æquinoctiall. [Now the way that thus cutteth through any field Eaſt and Weſt, ought to bee called Decumanus in Latine, or the Broad-way.] Which done, draw other two lines through the centre of the foreſaid circle, cutting one another aſlant [like S. *Andrewes* croſſe] in manner of the letter X, ſo as that line which at the one end pointeth to the right hand of the North, reach to the left hand of the South at the other. Likewiſe, that which regardeth the left ſide of the north at the one end, run directly to the right hand of the South with the other. All theſe lines muſt be of an even length, of equall diſtance one from another, and paſſe through the ſame Circle which we call the Navell. Having thus made the foure croſſe pathes or waies in every field once for all, thou maiſt ever after know how the winds doe ſtand. But if thou liſt to have ſuch a deviſe to ſerve
C thy uſe many times after, make a little inſtrument of wood, but the ſame as round as can bee by the compaſſe, and therein draw or print foure lines of an even length and equall diſtance, paſſing as Diameters all through the center, to the circumference of the rundle: and this may ſerve thee in ſtead of a Quadrant, where & whenſoever thou needeſt. The manner how to make and uſe this inſtrument, I am content thus to ſhew, becauſe I have to deale with ſimple ignorant men of dull wit and ſhallow conceit, who may ſoon erre & do amiſſe. Let us ſee then firſt, for the meridian line and the South point of the noone day, for to bee perfect therein; becauſe it is ever the ſame, and chaungeth not from one end of the yeare to another, whereas the Levant varieth every day, for that the Sunne never riſeth the morrow morning, from the ſame point juſt that hee roſe the day before: which I note, leaſt haply any man ſhould take one certaine line for to point out the
D Sunne riſing or the Eaſt, and make his Quadrant or compaſſe thereby. Now when thou haſt in this wiſe exactly ſet out the principall regions and quarters of the heaven, obſerve this, that the end or head of the line which is next to the North point Septentrio: on the Eaſt ſide, the ſame ſheweth the very place where the Sunne riſeth at the Summer Sunneſtead, to wit, the longeſt day of the yeare; and the wind there ſeated, is called in Latine Aquilo, *i.* the Northeaſt wind, and in Greeke Boreas. Thou knowing this perfectly, ſet thy trees and plant thy Vines full upon it. But ſo long as this wind bloweth, plough no lands, ſet no trees or plants that are to beare fruit, caſt no graine nor ſeed into the ground. For why? this wind peirceth, pincheth, and killeth the heart of any tree root above the ground, that thou ſhalt bring to replant. Take warning therfore beforehand, and be adviſed: for Experience hath taught, That one thing is good for ſtrong and
E ſturdie trees, and another for young and tender plants. Neither am I ignorant or forgetfull, that the Greekes have placed in this corner the wind which they name Cæcias: but *Ariſtotle* himſelfe a Philoſopher of an infinite ſpirit and high conceit (the man that hath ſo done) ſheweth a reaſon drawne from the convexitie and bending cope of the heaven, whereby the Northeaſt wind or Aquilo bloweth full oppoſite to the Southweſt Africus. Howbeit, the Husbandman is not afraid of this Northeaſt wind Aquilo all the yeare long, in thoſe particularities whereof hee is forewarned. For in the middeſt of Summer this wind doth moderate and temper the ardent heat of the ſtars raining and raging in that time: then chaungeth he his name, and [during the Dog-daies] is called Eteſias. When thou therefore feeleſt him blow cold, take heed and be not too bold. But learne this withall, that howſoever this wind may doe harme, in ſome ſuch reſpect, for which thou
F art forewarned; yet the wind Septentrio that bloweth plumbe North, is far more daungerous and miſchievous than he. Againſt the Northeaſt wind aforeſaid, let both hortyards, tree-rows, groves, and vineyards, be raunged; in all Natolia, Greece, Spain, maritine coaſts of Italie, Campain, and Apulia. If thou deſireſt to breed males, keepe thy cattell with their heads into this wind, and in that ſort let the females be covered.

Dextratus & Siniſtratus, Antiquis.

When

When thou haſt found out in this manner the Northeaſt wind Aquilo, be ſure that the wind which bloweth full againſt it, from the point where the Sun ſetteth in mid-winter when daies be ſhorteſt, is the Southweſt, called in Latin, Africus; and in Greeke, Lybs. Obſerve this wind well, for if a beaſt after ſhe be covered, turne about directly into this wind, ſhee will for certaine conceive a female. And thus much of the Line in thy quadrant next to the North point on the Eaſt ſide.

The third Line from the North point (which we drew firſt through the latitude of the ſhadow beforeſaid, and which we called Decumana) pointeth out the Æquinoctiall Sun-riſing in March and September; directeth thee alſo to the Eaſt wind under it, called in Latine Subſolanus, and in Greeke Apeliotes. Where the climat is healthfull and temperate, let vineyards be planted and arraunged into this wind: let ferme-houſes alſo in the countrey be ſo built, as the dores and windowes open into it. This wind loveth well to be dropping, and to diſtill gentle ſhowres of raine; howbeit dryer it is than the Weſt wind Favonius, which bloweth over-againſt him from the Æquinoctiall ſun-ſetting full Weſt, called in Greeke * Zephyrus. Vpon this Weſterne wind, Olive rowes ſhould ſtand, according to *Catoes* mind: this wind is hee that beginneth the Spring: this wind openeth the veines and pores of the earth, and with his mild coldneſſe is healthfull and holeſome for all plants, for man alſo and beaſt. This wind governeth this whole ſeaſon, and preſcribeth the time for pruning vines, for ſarcling and dreſſing corne, for planting trees, for graſſing fruit, for trimming and ordering Olives; and to ſay all in one word, ſo kind he doth breath, that he cheriſheth and foſtereth the earth, and all things thereupon.

* ζεφύρους. *Homer.*

The fourth Line in your Quadrant or Compaſſe (reckoning from the North point, which alſo reacheth next to the South point on the Eaſt ſide) noteth the Sun-riſing in mid-winter when the day is ſhorteſt; and withall the Southeaſt wind called in Latine Vulturnus, and in Greeke Eurus; which as it is a drier wind than the two laſt named, ſo is it alſo warmer: in regard whereof, it is good to ſet bee-hives and plant vines tending into this coaſt, I meane in other parts of Italy remote from the ſea, and alſo in Gaule. Then ſhall you have to blow full oppoſite unto it, the wind Corus, directly from the ſun-ſetting in mid-ſummer when the day is longeſt, by-weſt from the North; and this Northweſt wind the Greekes call Argeſtes: one of the coldeſt he is, like as all they be which blow from any point of the North. No marveile therefore if hee be as much dread & feared as the North wind Septentrio, for commonly he bringeth with him haile ſtorms good ſtore.

As touching the Southeaſt wind Vulturnus, if the coaſt be cleare where and when he beginneth to riſe, it will not be long ere he lie, and commonly he is downe before night: but the Eaſt wind in deed continueth moſt part of the night. But be the wind what he will be, if he blow ſenſibly hot, you ſhall have him hold many daies togither. And to conclude, would you know when to have a Northweſt wind? marke when the earth drieth ſuddainly at one inſtant, it will not bee long but he will be with you: contrariwiſe, when you ſee the ground moiſt and wet with a kind of ſecret dew unſeene and unknowne, reckon upon it that ſhortly you ſhall have a South wind to blow. And thus much for Winds.

Chap. xxxv.

Signes to prognoſticate what weather is toward.

HAving thus ſet downe ſufficiently a diſcourſe of the Winds, becauſe I would not reiterate one thing often, what remaineth now, but in good order to paſſe and proceed to the prognoſtication and foreknowledge of the weather? and the rather, for that I ſee that *Virgil* tooke great pleaſure herein and ſtood much upon this point: for thus he relateth unto the rude and ignorant men of the countrey, That oftentimes in the very mids of harveſt, hee hath ſeene whirle-puffs and contrarie winds, encounter and charge one another as it were in battaile, doing much harme to corne. Moreover, it is reported, that *Democritus* at what time as his brother *Damaſus* was entred well into harveſt-worke, taking the opportunitie (as he thought) of a moſt hot ſeaſon, beſought him earneſtly to let the reſt of his corne to ſtand ſtill a while longer, and to make haſt to get that into the barne under roufe which was cut and reaped downe; & this he did without any reaſon by him made, why and wherefore. And what enſued hereupon? Surely within few houres after, there powred downe a mightie ſhowre of raine, and prooved *Democri-*

tus

A *tus* to be a wiſe man and a true prophet. Moreover, it is a rule commonly given and obſerved; That neither Reeds would be ſet and planted but toward raine, nor corn ſowed but againſt a good ſhowre. And therefore ſince this skill is of ſuch importance, I am content briefly to touch thoſe ſignes that foreſhew what weather will be, and make choice of ſuch which by ſearch and experience are knowne principall and make moſt for this purpoſe.

And firſt begin I will at the Sun, the beſt prognoſticator of all others: When he riſeth cleare and not fiery red, it is a ſigne that the day will be faire; but if he ſhew pale and wan, it preſageth a cold winter-like haile-ſtorme that very day: but in caſe hee went downe over-night cleare and bright, and ſo roſe the next morning, ſo much ſurer may you bee of faire weather. If the Sun in riſing ſeeme hollow, he foretelleth raine: and when before his riſing the clowds be red, the winds
B will bee aloft that day: but in caſe there be ſome blacke clowds intermingled among, you ſhall have raine withall. If the raies and beames of the Sun be red, both when he riſeth and when hee ſetteth, there will fall good ſtore of raine. Are the clowds red about the Sun as he goeth down? you ſhall have a faire day the morrow after. If when the Sun doth riſe you ſee flying clowds diſpearſed, ſome into the South and others Northward (ſay all be cleare and faire otherwiſe about him) make reckoning that day of wind and raine both. Marke at his riſing or going downe, if his beames be ſhort and as it were drawne in, be ſure of a good ſhowre. If at the Suns ſetting it raine, or that his raies either looke darke and blew, or gather a banke of clowds, ſurely theſe be great tokens of tempeſtuous weather & ſtorms the morrow after. When in his riſing the beams ſhine not bright and cleare, although they be not over-caſt with a clowd, yet they portend raine.
C If before he riſe, the clowds gather round togither like globes, they threaten ſharpe, cold, and winter weather: but in caſe hee drive them before him out of the Eaſt ſo as they retire into the Weſt, we have a promiſe thereby of a faire time. If there appeare about the bodie of the Sun, a circle of clowds compaſſing it round, the nearer they come about him and the leſſe light that they leave him, the more troubled and tempeſtuous weather will follow: but in caſe he be environed with a double circle, ſo much more outragious and terrible will the tempeſt be. If peradventure this happen at his riſing, ſo as the ſaid clowds be red againe which compaſſe the Sunne, looke for a mightie tempeſt one time or other of that day. If haply theſe clowds encloſe him not round, but confront and ſeeme as if they charged upon him, looke from whence they come, from that quarter they portend great wind: and if they encounter him from the South, there
D will be raine good ſtore and wind both. If as the Sun riſeth he be compaſſed with a circle, marke on what ſide the ſame breaketh and openeth firſt, and from thence looke for wind without faile: but if the ſaid circle paſſe and vaniſh away all at once equally, as well of one part as another, you ſhall have faire weather upon it. If at his riſing you ſee him to caſt his beams afar off among the clowds, and the mids between be void thereof, it ſignifieth raine. If he ſpread his beams before he be up and appeare in our Horizon, looke for wind and water both. If about him toward his going downe there be ſeene a white circle, there will bee ſome little tempeſt and troubleſome weather that night enſuing: but if in ſtead thereof hee be over-caſt with a thicke miſt, the tempeſt will be the greater and more violent. If the Sun couchant appeare fiery and ardent, there is like to bee wind. Finally, if the circle aforeſaid bee blacke, marke on which ſide the ſame brea-
E keth, from thence ſhall you have bluſtering winds. And ſo an end of the Sunne and his prognoſtications.

Now by right, the Moone challengeth the next place for her preſages of weather to come. Firſt and foremoſt, the Ægyptians obſerve moſt her Prime, or the fourth day after the chaunge: for if ſhe appeare then, pure, faire, and ſhining bright, they are verily perſuaded that it will bee faire weather: if red, they make no other reokoning but of winds: if dim and blackiſh, they looke for no better than a foule and rainie moneth. Marke the tips of her hornes when ſhe is five daies old, if they be blunt, they foreſhew raine; if pricking upright and ſharpe pointed withall, they alwaies tell of winds toward: but upon the fourth day eſpecially, this rule faileth not, for that day telleth trueſt. Now if that upper horne of hers only which bendeth Northward, appeare ſharpe
F pointed and ſtiffe withall, it preſageth wind from that coaſt: if the nether horne alone ſeeme ſo, the wind will come from the South: if both ſtand ſtreight and pricking at the point, the night following will be windie. If the fourth day after her chaunge, ſhe have a red circle or Halo about her, the ſame giveth warning of wind and raine. As for *Varro*, hee (treating of the preſages gathered from the Moone) writeth thus: If (quoth he) the new moone when ſhe is juſt foure daies

old,

old, put her horns direct and ſtreight forth, ſhe preſageth thereby ſome great tempeſt at ſea preſently to follow, unleſſe it be ſo that ſhe have a guirland or circle about her, and the ſame cleare and pure; for then there is good hope that there will be no foule nor rough weather before the full. If at the full, one halfe of her ſeeme pure and neat, a ſigne it is of a faire ſeaſon; if it be red, the wind will be buſie; if enclined to blacke, what elſe but raine, raine. Doe you ſee at any time a darke miſt or clowd round about the body of the moone? it betokeneth winds from that part where it firſt breaketh: and in caſe there bee two ſuch clowdie and miſtie circles environing her, the tempeſt will bee the greater: but how if there bee three of them for failing, and thoſe either blacke, or interrupted, diſtracted and not united? ſurely then there will be more ſtormes & more. The new moone whiles ſhee is croiſſant, if ſhee riſe with the upper tip or horne blackiſh, telleth beforehand that there will be ſtore of raine after the full, and when ſhe is in the wane: but if the nether tip be ſo affected, the rain will fall before ſhe be at the full. But what if that blackneſſe appeare in the middle of her bodie between? then (ſaith *Varro*) it will powre of rain in the very full. A full moone having about her a round circle, ſheweth that there will bee wind from that part, where the ſaid circle is moſt ſplendant. If her hornes appeare when ſhe riſeth, more groſſe and thicke than ordinarie, looke ſoone after for a terrible tempeſt and ſtormie weather. If ſhee ſhew not in our Horizon before the prime or fourth day after the chaunge, and the Weſt wind blow withall, then that moone throughout threatneth cold and winter weather: and if the day after the full ſhe ſeeme extraordinarily enflamed, ſhee menaceth unto us ſharpe ſhowres and bitter tempeſts. Finally, in every moone there be eight points and ſo many daies (according as ſhe lighteth upon the angles of the Sunne) which moſt men obſerve onely, and take their preſages of future weather by, to wit, the third, ſeventh, eleventh, fifteenth, nineteenth, one and twentieth, ſeven and twentieth, and the very day of her conjunction or chaunge.

In the third place, a man may know the diſpoſition of the ſeaſons by the fixed ſtars, & therefore it behooveth to obſerve and marke them. They ſeeme otherwhiles in the skie to flit and run too and fro, and then wee ſhall not be long without great winds, riſing from that quarter where ſuch appeared and gave token.

The ſtarrie skie, if it ſhew cleare and bright all over, and in every part alike, during that particular ſeaſon [namely, betweene the occultation of the Harp-ſtar, and the Æquinoctiall point] which I propoſed and ſet downe heretofore, it is a fore-token of a faire and drie Autumne, but yet cold.

If the Spring and Summer both, paſſed not cleare without ſome raine and wet weather, it will bee an occaſion that the Autumne following ſhall be drie, and leſſe diſpoſed to wind; howbeit, thicke, muddie, and enclined to miſts. A faire and drie Autumne, bringeth in alwaies a windie winter.

When all on a ſodaine the ſtars looſe their brightneſſe and looke dim, and that neither upon a clowd nor a miſt in the aire, it ſignifieth either raine, or grievous tempeſts.

If the ſtarres make ſemblance as if they flew up and downe many togither, and in their flying ſeeme whitiſh, they denounce winds from that coaſt where they thus do ſhoot. Now if it ſeeme to the eye, as if they ran and kept one certaine place, thoſe winds will hold and ſit long in one corner: but in caſe they do ſo in many quarters of the heaven, they betoken variable and inconſtant winds, going and comming, and never at reſt. [When you ſee a circle about any of the other five planets or wandring ſtars, you ſhall have powring ſhowres ſoone after.] Within the ſigne Cancer, there be two pretie ſtars which the Mathematicians call Aſelli, [*i.* little Aſſes] betweene which there ſeemeth to be a ſmall clowd taking up ſome little roome, and this they name in Latine Præſepia, [*i.* a Crib, Crafch, Bowzey, or Manger:] now if it chaunce that this Racke or Crib appeare not, and yet the aire be faire and cleare otherwiſe, a ſigne it is of cold, foule, and winter weather. Alſo if the one of thoſe two little ſtars, to wit, that which ſtandeth Northerly, be hidden with a miſt, then ſhall you have the South wind to rage; but in caſe the other which is more Southerly, be out of ſight, then the Northeaſt wind will play his part.

As touching the Rainbow, if it appeare double as if there were two of them at once, it telleth of raine toward. A Rainbow preſently after raine, is a ſigne of faire weather: but this is not ſo certein, neither will it hold long. Alſo, when a man ſeeth new circles ſtill about any planets, there will be much raine ſoone after.

In Summer time, if there chaunce to bee more thunder than lightning, it threatneth winds from

A from that coast where it thundred: contrariwise, if it lighten much & thunder little, looke for rain plentie: when you see it lighten, and the skie otherwise cleare and faire, it is a token that rain and thunder will follow thereupon, yea and rigorous cold weather besides: but the cruellest and most bitter impressions of the aire, ensue upon such lightnings as come from all the foure quarters of heaven at once: if it lighten from the Northwest onely, it betokeneth raine the day following; if from North, it is a signe of wind from thence: if from the South, Northwest, or full West, it happen to lighten in the night & the same be faire, it sheweth wind and rain from out of those coasts: morning thunders foreshew winds; but if they be heard at noone, they presage store of raine.

As touching clouds, if you see the racke ride apace in the aire, the weather beeing faire and drie, looke for wind from that quarter whence those clouds do come; and if they seeme to gather B thicke in that place, dispearsed they will bee and scattered when the Sun approacheth: but more particularly, if this happen from the Northeast, they portend raine; if from the South, storme and tempest: if at the Suns setting the racke seeme to ride from both sides of him into the open aire, they shew of tempests toward: if the clouds be exceeding black, flying out of the East, they threaten raine against night; but if they come out of the West, it will surely raine the morrow after: if the clouds be disparkled many togither out of the East, and flie like fleeces or flockes of wooll, they shew raine for three daies after: when clouds flie low, and seeme to settle upon the tops of the hills, looke shortly for cold weather: contrariwise, if you perceive those tops of mountaines cleare without mist or cloud, the weather will soon take up and turn to be faire: when the clouds seeme to be heavily charged and full, and yet looke white withall (which * constitution of the aire C is called commonly the white weather) there is an haile-storme at hand: moreover, bee the skie never so cleare, the least cloud appearing therein, is enough to engender and foreshew wind and storme: mists if they come downe and fall from the mountains, or otherwise descend from heaven and settle upon the vallies, promise a faire and drie season.

* Some call them Towers.

Leaving the starres and clouds above, let us come to our fires that we make and keepe in our houses here beneath, for they are to be raunged in the next place of our prognostication. If the fire then burne in the chimney pale, and keepe therewith a huzzing noise, wee find by experience that it foresheweth tempest and stormie weather: as also we may be sure of raine, in case wee see a fungous substance or soot gathered about lamps and candle snuffs: if you see the flame either of fire or candle mount winding and waving as it were, long you shall not be without wind. The like is to be said of fire and candle light, if either they seeme to goe out of themselves, or to kindle and take fire with much adoe. Also, when we discerne in the fire a number of sparkles gathered togither and hanging one to another: or if when the pot is taken off from the fire, the coles sticke to the bottome and sides: or when the fire being raked in embres, keepeth a spitting and sparkling from it: also, if the ashes lying upon the hearth grow togither: and last of all, when the live-cole shineth brighter or scorcheth more than ordinarie: all these be signs of raine.

Goe we a little lower to the water, for that element also giveth signes of the weather: and first of all, if you see the sea within the haven, after the floud is gone, in a low and ebb water to bee calme, and yet heare it keepe a rumbling noise within, it foreshewth wind: if it doe thus by times and fits one after another, resting still and quiet between-whiles, it presageth cold weather & rain: *Item*, if in calme and faire weather the sea strond or water banks resound and make a noise, it is a token of a bitter tempest: so it fareth also with the very sea it selfe; for if it be calme, & yet make a roaring; or if the fome therof be seen to scatter too & fro, or the verie water to boile & buble, you may be bold to foretell of tempests: the Puffins also of the sea, [*i.* fishes named in Latin Pulmones] if they appeare swimming above water, do foresignifie cold wether for many daies togither: oftentimes the sea being otherwise calme, swelleth, & by hooving higher than ordinarie, sheweth that she hath wind good store enclosed within her, which soon after will breake out to a tempest.

Let us come aland againe, and marke the disposition of woods and hills: you shall heare the mountains and forests both, keep a sounding and rumbling noise, and then do they foretell some change of weather: nay you shall marke the leaves of trees to move, flicker & play themselves, and yet no wind at all stirring; but be sure then that you shall not be long without. The like prediction is to be gathered by the light downe either of poplars or thistles flying too and fro in the aire; also of plumes and feathers floting upon the water. Goe downe lower to the vales and plaines: if a man chaunce to heare a bustling there, he may make account that a tempest will follow. As for the rumbling in the aire, it is an undoubted signe and token thereof.

Moreover, the verie bruit and dumbe creatures preſage and give warning, what weather there will be. To begin with fiſhes of the Sea: the dolphins playing and diſporting themſelves in a calme water, doe certainely fore-ſhew wind comming from that coaſt whence they fetch theſe friskes and gambols: contrariwiſe, if they fling and daſh water this way and that way, the ſea at that time being rough and troubled, it is an infallible ſigne of a calme and of faire weather toward. The Cuttle or little Calamarie Loligo, launching it ſelfe and flying above the water; the Cockles and Winkles cleaving and ſticking hard to the gravell; the Sea-urchins thruſting themſelves into the owſe and mud, or otherwiſe balaiſed and covered with ſand, be all ſigns of tempeſts neare. The like may bee ſaid of Froggs, when they crie more than their cuſtome is; and of Sea-mews alſo, when they gaggle in a morning betimes extraordinarily: ſemblably, the Cormorants, Gulls, Mallards, and Ducks, when they keepe a proining of their feathers with their bills, foreſhew wind: and generally, when you ſee other water-foule to gather and aſſemble togither and then combat one with another, or Cranes make haſt to flie into the midland parts of the maine. The Cormorants and Gulls flying from the ſea and ſtanding lakes, and Cranes ſoaring aloft in the aire ſtill, without any noiſe, doe put in comfort of a faire and drie ſeaſon: ſo doth the Howlat alſo, when ſhee cries chuitt in rainie weather: but if it be then faire and drie, we ſhall be ſure to have foule tempeſts for it afterwards: Ravens crying one to another as if they ſobbed or yexed therewith, and beſides clapping themſelves with their wings, if they continue this note, doe portend winds; but if they give over between-whiles, and cut their crie ſhort as if they ſwallow it backe againe, they preſage raine and wind both. Iacke-dawes, if it be late ere they returne from their reliefe abroad, foretoken cold and hard weather; ſo doe the white-birds when they aſſemble and flock togither, as alſo when land-foule (and the crow eſpecially) keepe a crying againſt the water, clapping their wings, waſhing alſo and bathing themſelves. If the ſwallow flie low and ſo neare the water, that ſhe flap the ſame oftentimes with her wings, it is a ſigne of raine and foule weather. Semblably, all other birds that neſtle in trees, if they ſeeme to make many flights out, but returne quickely againe to their neſts. Moreover, if Geeſe hold on a continuall gaggling out of all order untunably, a man may gueſſe no better by them, no more than he can of the Heron which he ſeeth heavie and ſad upon the ſands.

And no marveile that theſe river-foules, or generally any other birds of the aire whatſoever, ſhould have a ſecret preſage and foreknowledge of the diſpoſition of the aire; for the very four-footed beaſts of the earth doe make ſhew thereof by their behaviour. The ſheepe and ſuch ſmall cattaile, leaping and playing wantonly, dauncing alſo as untowardly without meaſure, doe teſtifie ſome chaunge of weather: nay the dull and heavie oxen holding up their noſe and muzzles, ſnuffe and ſmell into the aire, yea and keepe a licking againſt the haire [toward raine.] Alſo, when you ſee the foule and filthie hoggs, rend, teare, and fling about them bottles of haie, and yet they care not for it when they have done, becauſe it is no meat for them: likewiſe if you perceive the piſmires or ants either lying cloſe and idle, full againſt their nature (whoſe propertie is to be induſtrious and ever buſie) or encountring one another in battaile-wiſe, or els carrying their eggs abroad out of their holes. Finally, when the mads or earthworms come forth and appeare, a man may be bold to foretell of a chaunge in the weather.

What ſhould I ſay more? It is knowne for certaine, that the Claver-graſſe or hearbe Trefoile will looke rough againſt a tempeſt, yea and the leaves thereof will ſtand ſtaring up as if it were affraid thereof. And to conclude and make an end once of this diſcourſe, whenſoever you ſee at any feaſt the diſhes and platters wherein your meat is ſerved up to the bourd, ſweat or ſtand of a dew, and leaving that ſweat which is reſolved from them, either upon dreſſer, cupbourd, or table, be aſſured that it is a token of terrible tempeſts approaching.

An

An Index pointing to the principall matters contained in the first Tome of *Plinies* Naturall Historie.

THE HISTORIE OF THE WORLD.

Commonly called,

THE NATVRALL HISTORIE OF C. PLINIVS SECVNDVS.

Translated into English by PHILEMON HOLLAND
Doctor of Physicke.

The second Tome.

LONDON,
Printed by Adam Islip.
1601.

THE
HISTORIE
OF THE WORLD.

Commonly called,

THE NATURALL HISTORIE OF
C. PLINIVS SECVNDVS.

Translated into English by Philemon Holland
Doctor of Physick.

The second Tome.

LONDON,
Printed by Adam Islip.
1601.

TO THE READER.

FOr as much as this ſecond Tome treateth moſt of Phyſicke, and the tearms belonging thereto (as well concerning diſeaſes as medecines) be for the moſt part either borrowed from the Greeke, or, ſuch as the unlearned be not acquainted with, (which partly upon neceſsitie I was forced, and partly for varietie induced to uſe) I could not content my ſelf to let them paſſe without ſome explanation: For ſince my purpoſe eſpecially is to profit and pleaſure the moſt ignorant (for whoſe ſake *Plinie* alſo himſelfe, as he profeſſeth, compiled this worke) I would not bee ſo injurious unto them as to interrupt their reading with obſcuritie of phraſe, when the matter otherwiſe is moſt familiar. In regard whereof, I thought good to prefixe a briefe Catalogue of ſuch woords of Art, as ever and anon ſhall offer themſelves in theſe diſcourſes that enſue, vvith the explanation thereto annexed, and the ſame delivered as plainly as I could poſsibly deviſe for the capacitie of the meaneſt. In the handling whereof, ſo I may ſatisfie my countreymen that know no other language but Engliſh, I ſhall thinke my paines and labour well beſtowed, and leſſe feare the cenſure of thoſe that haply expect ſome deeper learning: for ever ſtill

the verse of that Comicall Poet resoundeth from the stage in mine ears,

ἀμαθέστερον φρόνησον ἢ σαφέστερον. *id est,*

Speake with lesse shew of learning, so it bee with more perspicuitie. Vale.

A briefe Catalogue of the words of Art, with the explanation thereof.

A

ABort, or *abortive fruit*, is an untimely birth.

Abſterſive, *i.* ſcouring, cleanſing, or wiping away, ſuch as the Greeks call Smectica, and they enter into ſope and waſhing balls.

Acceſſe, *i.* a fit, whether it be of an ague, falling ſickneſſe, or any ſuch diſeaſes as returne at times.

Acetabulum, or *Acetable*, a meaſure among the Romans of liquor eſpecially, but yet of drie things alſo: the ſame that Oxybaphon in Greeke: and for that (as both words do import) they uſed to dip their meats in vinegre out of ſuch, it may well goe for a saucer with us: for it containeth (as ſome thinke) fifteen drams, which grow near to two ounces, of which capacitie our ſmall saucers are: but as others ſuppoſe, it receiveth two ounces and an halfe, the meaſure of ordinarie saucers.

Acrimonie, *i.* Sharpneſſe.

Actually, *i.* ſenſibly and preſently, as fire is actually hot.

Aditiales, or *Adjciales epulæ*, were great and ſumptuous feaſts or ſuppers, held by the Pontifices or high prieſts, in teſtimonie of publicke joy.

Almonds. See *Amygdals*.

Amphora, a meaſure in Rome of liquors only: It ſeemeth to have taken that name of the two ears which it had, of either ſide one: it contained eight Congios, which are much about eight wine gallons, or rather between ſeven and eight: ſo as in round reckoning it may go for a ferkin, halfe kilderkin, or halfe ſeſterne with us.

Amygdals, be kernils at the root of the tongue, ſubject to inflammations and ſwellings, occaſioned by deflux or falling downe of humours from the head: they be called Antides, Pariſthmia, and Tonſillæ: the foreſaid infirmities alſo incident unto them, do likewiſe carie the ſame denominations.

A

Antidotes, *i.* countrepoiſons properly, defenſatives, or preſervatives againſt poiſons, peſtilence, or any maladie whatſoever.

Antipathie, *i.* contrarietie, enmitie, and repugnancie in nature, as between fire and water, the vine and the Colewort, &c.

S. Anthonies fire is a riſing in the skin, occaſioned by hote bloud mixt with abundance of choller, and ſuch be the ſhingles and other wildfires called in Greeke Eryſipelas.

Aquoſities, be wateriſh humours, apt to engender the dropſies called Aſcites and Leucophlegmatia.

Aromatized, *i.* Spiced.

Arthriticall griefs, ſuch as poſſeſſe the joynts, as all the ſorts of gout.

Aſtrictive or *Aſtringent*, be ſuch things as bind the bodie or any part thereof.

Attractive, *i.* drawing; as the loadſtone draweth yron, amber ſtraws or bents, Dictamnus arrow heads or ſpills out of the bodie, and cupping-glaſſes (or ventoſes) humours and wind.

Auſtere, harſh or hard, as in fruits unripe, and hard wines of hedge grapes.

Axinomantie, a kind of magicke divination by an axe head red hot.

B

BAſis in a compound medecine is, that drug or ſimple which is predominant and carieth the greateſt force in it, as the ground therof, whereupon the whole taketh the name; as Poppie in Diacodion, Quinces in Diacydonium, &c.

Bole, is the forme of a medecine when it may be given in groſſe manner at a knives point to the quantitie of a nutmeg at a time, untill the whole receit be taken.

Browning, a tearme uſuall in the mouths of mariners and winnowers of corne, when they are calmed and doe call for wind.

Bulbs, although *Plinie* ſeemed to give that name unto ſome one ſpeciall hearbe, yet it

ſignifieth generally all thoſe as have round roots, as Onions, Squilla, Wakerobin, and ſuch like; whereupon theſe & other of that kind are ſaid to have bulbous roots.

Cacochymie, is that indiſpoſition of the bodie wherein there is abundance of ill humours.

Calcining, *i.* the burning of a minerall, or any thing, for to correct the malignitie of it, or reduce it into powder, &c.

Calloſitie, thickneſſe and hardneſſe of skin in manner ſenſleſſe, as in fiſtulaes, and under our heels.

To *Carminate*, is to make more fine and thin the groſſe humors, by ſuch medicins as by their heat are apt to cut and diſſolve them; wherupon they likewiſe be called *Carminative:* a tearme received by Apothecaries, and borrowed from thoſe that card wooll.

Cancer, is a ſwelling or ſore comming of melancholie bloud, about which the veins appeare of a blacke or ſwert colour, ſpread in manner of a Creifiſh clees; whereupon it tooke that name in Latine, like as in Greeke *Carcinoma*. And ſuch ulcers as in that ſort be maintained and fed with that humor, are called Cancerous, & be untoward to heale, worſe commonly for the handling.

Carnoſitie, *i.* fleſhly ſubſtance.

Cataplaſm, a pulteſſe or groſſe maner of plaſtre.

Cartilage, in man and beaſt, is a griſtle; in roots and fruits, that ſubſtance which we obſerve in the Radiſh root, and the outward part of the Cucumber, as *Plinie* ſeemeth to take it; which therupon be called Cartilagineous.

Cataract, is a dimneſſe of ſight cauſed by an humor gathered and hardened between the tunicle of the eye called Cornea, and the Cryſtalline humour; it is next couſin to blindneſſe.

Cauſticke, *i.* burning, bliſtering, or ſcalding.

To *Cauterize*, is to ſeare or burn by a Cauterie.

Cauterie actuall, is fire it ſelfe, or ſcalding liquor: and ſo a ſearing yron, gold or other mettall made red hot, is called an Actuall cauterie, which without the help of our naturall heat doth worke preſently.

Cauterie potentiall, is that which will raiſe bliſters and burn in time after it is once ſet on worke by the heat of our bodie, as Canthorides, Sperewort, &c.

Ceres, the firſt inventreſſe of corne, the ſowing and uſe thereof.

Cerote, is of a middle nature, between an ointment and a plaſtre, not ſo hard as the one nor ſo ſoft as the other.

Cicatrices in eyes, bee whitiſh ſpots, otherwiſe called Pearls: they be the skarrs alſo remaining after a ſore is healed up: and ſo a place is ſaid to bee cicattized, when it is newly skinned up and healed.

Circulation, is the deviſe of ſubliming or extracting water or oile, by a ſtillatorie, a lembicke, or ſuch, becauſe the vapour before it be reſolved into water or oile ſeemeth to go round circlewiſe.

Clyſterized, *i.* conveighed up by a clyſter into the guts.

Cæliaci, be thoſe that through weakneſſe of ſtomacke are troubled with a continuall flux of the bellie.

Colature, a thin liquor that hath paſſed thorow a ſtrainer or colander.

Colliquation, is a falling away, & conſumption of the radicall humour, or ſolid ſubſtance of the bodie.

Collyries, are properly medicins applied to the eies in liquid forme; whereas the drie kind be rather called Sief & Alcohol, eſpecially in powder: howbeit *Plinie* attributeth this tearme to all eyeſalves whatſoever. Alſo it ſeemeth that he meaneth thereby, tents to be put in a fiſtulous ulcer, as in the pa. 509 *b*. 510 *k*.

Collution, a liquor properly to waſh the mouth, teeth, and gumbs withall.

Concocted, *i.* altered to that ſubſtance by naturall heat, as either in health may ſerve to nouriſh, or in ſickneſſe is apt to be expelled.

Conſolidat, to knit, unite, & make ſound againe that which was broken or burſt.

Concrete, *i.* hardened and growne thicke.

Condite, *i.* preſerved in ſome convenient liquor.

To *Concorporat*, *i.* to mix and unite togither into one maſſe.

Conſiſtence, *i.* ſubſtance or thickneſſe.

Conſtipate, *i.* to harden and make more faſt and compact.

Contraction in ſinews, a ſhrinking or drawing of them in too ſhort.

Contuſions, *i.* Bruiſes.

Convulſions, painfull cramps.

Criticall daies be ſuch, as in ſhort diſeaſes and thoſe of quicke motion, doe give light unto the Phyſician of life or death. *Plinie* obſerveth the odd daies to be moſt ſignificant, and thoſe uſually determine of health; and the even daies contrariwiſe: ſo that the ſeventh is *Rex*, *i.* a gracious prince; the ſixth *Tyrannus*, *i.* a cruell tyrant.

Cruditie. See *Indigeſtion.*

Cyath, a ſmall meaſure, both of liquid and drie things; the twelft part of a Sextarius, which was twentie ounces: whereby it appeareth, that a cyath was one ounce, one half ounce, one dram, and one ſcruple: it may goe with us for foure ordinarie ſpoonefuls.

Cubit, a meaſure, from the elbow to the middle finger ſtretched forth at length, which went ordinarily for 24 fingers breadth or 18 inches, which is one foot and an halfe: yet *Plinie* in one place maketh mention of a ſhorter cubit, namely from the elbow to the end of the fiſt or knuckles, when the fingers bee drawne in cloſe to the hand.

Cutanean eruptions, bee ſuch wheales, puſhes, or ſcabs, as doe breake out of the skin, and disfigure it.

D

Debilitie, *i.* weakeneſſe or feebleneſſe.

Decoction, a liquour wherein things have beene ſodden.

Decretorie daies, be ſuch in a ſickneſſe, as ſhew ſome chaunge or alteration in the patient, either for good or bad.

Defenſative, in medicines taken inwardly, are thoſe which reſiſt venome or peſtilent humor: in outward applications, ſuch as defend the ſore or place affected from the flux or fall of humours thither.

Denarius, a coine of ſilver in Rome, and in other countries of gold, the ſame that Drachma Attica, *i.* a dram in weigt, which is *vij. d. ob.* of our money; and the peece in gold anſwereth neare to a full French crowne. In poiſe it goeth for a dram.

Dentifrices, are meanes in Phyſicke to preſerve the teeth, and make them white and faire.

Depilatorie, are thoſe medicines which either fetch off the haire, or hinder it from comming up againe at all, or at leaſtwiſe from growing thicke. They were called in Greeke and Latine both, *Pſilothra.*

Deſiccative, *i.* drying.

Digeſtives, be thoſe medicines, which taken inwardly, helpe concoction of meat or humors; or applied without unto a ſore, doe comfort the place, and make way for ſpeedy healing.

Diſlocations, when the bones bee either out of joint, or elſe diſplaced.

To *Diſopilate*, *i.* to open.

To *Diſſipate*, *i.* to ſcatter and diſpatch.

Diſtortion, crookedneſſe or turning awrie unnaturally.

Diuretical, ſuch things as provoke urine.

Doſe, *i.* that weight or quantitie of any medicine that may be given either conveniently or without daunger to the patient.

Dram, the eight part of an ounce, which is the weight of a Romane denier or Denarius.

Dyſenterie, is properly the exulceration or ſore in the guts, whereupon enſueth beſides the painefull wrings of the bellie, a flux alſo of bloud at the ſeege, and therefore it is uſually taken for the bloudie flix.

E

Eclogues. See *Eidyls.*

Electuaries, bee medicinable compoſitions or confections to be taken inwardly, made of choiſe drougs, either to purge the humors, to ſtrengthen the principall parts, or to withſtand any infirmitie for which they are made. The ſubſtance is betweene a ſyrrup and a conſerve, but more enclining to the conſiſtence of conſerves.

Eidylls, or *Eidyllia*, bee ſmall Poëmes or Pamphlets written by Poëts, ſuch as *Theocritus* in Greeke compiled, and much like unto the Paſtorals or Eclogues of *Virgil* in Latine.

Embrochation, is a deviſe that Phyſicians have for to foment the head or any other part, with a liquour falling from aloft upon it, in manner of raine; whereupon it tooke the name in Greeke Embroche, and hath found none yet in Latine, unleſſe we ſhould uſe Superfuſio.

Emollitives, medicines that do ſoften any hard ſwelling.

Empirickes, were thoſe Phyſicians, who without any regard either of the cauſe in a diſeaſe, or the conſtitution and nature of the patient, went to worke with thoſe medicines whereof they had experience in others, fall it out as it would.

Empiricke bookes of *Diodorus*, contained receits approved and found effectuall by experience.

Emunctories, bee thoſe kernellie places in the bodie, by which the principall and noble parts doe void their ſuperfluities, or ſuch things as offend; to wit, under the eares for the braine, the arme-pits for the heart, and the ſhare for the liver, &c.

Empla-

Emplaſtration in the Hortyard, is grafting by inoculation with a ſcutcheon; in Phyſick, the applying of a ſalve or plaſtre.

Epilepſie, *i.* the falling ſickneſſe.

Errhines be deviſes made like tents, ſharper at one end than the other, to bee put up into the noſe, either to cure ſome ulcer there, or to draw downe and void humors out of the head, or to provoke ſneeſing, &c.

Eſchare, is that cruſt which ariſeth upon a cauterie, either actuall or potentiall, as alſo the rouſe or ſcab that groweth upon a ſore.

Evacuation, *i.* Voidance and riddance of any thing out of the bodie by vomite, purging, bleeding, ſweating, &c.

Excalfactorie, *i.* Heating or chauſing.

Excoriation, *i.* fretting the skin off, when a part is made raw: a way to exulceration.

Excreſcence, *i.* overgrowing unnaturally of any thing in mans bodie.

Exoticall, *i.* forraine, and brought from other countries.

Exorciſmes, *i.* coniurations by certain charmes and ſpels.

Exorciſts, they that practiſed ſuch Exorciſmes.

To *Expectorat*, *i.* to rid and diſcharge out of the breaſt by coughing or reaching.

Expiatorie, were ſacrifices or oblations for to make ſatisfaction and attonement.

Exiccative. See *Deſiccative*.

Extenuat, *i.* to make thin.

Exulceration, *i.* a ſoreneſſe of any part inward or outward, when not onely the skin is off, but the humor doth fret deeper ſtill.

Exulcerative, bee ſuch things as are apt to eat into the fleſh and make an ulcer.

F

FErmentation, *i.* an equall mixture of things working as it were together: a tearme borrowed from the levaine, which diſperſeth it ſelfe into the whole maſſe or lumpe of dough.

Filaments bee the ſmall ſtrings that hang to a root like threads or haires, which ſome call the beard of the root: and in reſemblance thereof, other things growing likewiſe, bee ſo called.

Fiſſures, clifts, or chaps, whether it bee in the hands, feet, lips, or fundament.

Flatuoſities, *i.* windineſſe gathered within the bodie.

Flora, the goddeſſe of Flowers among the Painims.

Fomentations properly be deviſes for to be applied unto any affected part, either to comfort and cheriſh it, or to allay the paine, or elſe to open the pores to make way for ointments and plaſtres. If they be liquid things, they are laid too by the meanes of bladders, ſpunges, or ſuch like: if drie, within bags or quilts.

Fractures, *i.* bones broken.

Frictions or *Frications*, rubbings of the bodie upward or downeward gently or otherwiſe, as the cauſe requireth.

Frontall, the forme of an outward medicine applied unto the forehead, to allay pain, to procure ſleepe, &c.

Fukes, *i.* paintings, to beautifie the face in outward appearance. They are called at this day complexions, whereas they bee cleane contrarie: for the complexion is naturall, and theſe altogether artificiall.

Fumoſities bee vapours ſteaming up into the head, troubling the braine.

Fungous, *i.* of an hollow and light ſubſtance like to Fuſſes or Muſhromes.

G

GArgariſmes bee collutions of the mouth, and parts toward the throat, either to draw downe and purge humours out of the head, or to repreſſe and reſtraine their flux, or to mundifie and heale any ſore there growing.

Gargariſing or Gargling is the action of uſing a liquor to the ſaid purpoſe.

Geſtation, an exerciſe of the bodie, by beeing carried in coach, litter, upon horſebacke, or in a veſſell on the water.

Glandulous ſwellings. See *Kings evill*.

Gleir, *i.* the white of an egge.

Gymnicke exerciſes, were thoſe that were performed by men naked, and the place for ſuch exerciſes, was thereupon called Gymnaſium.

H

HAbit of the bodie, is taken for the outward parts therof, oppoſit unto the bowels and principall within; which beeing comforted and fortified, doe thruſt forth offenſive matters to the habit and exterior skin.

Hemine, a meaſure in Rome, as well of liquors as drie things: ſo called, becauſe it was halfe Sextarius: it contained ten ounces, and is

ſomewhat

ſomewhat under our wine pint, it is the ſame that Cotyla in Greeke.

Humiditie, i. moiſture.

Hydromantia, a kind of magicall divination or foreknowledge of things to come, by obſervation of the water.

Hydrophobie, is a ſymptome or accident befalling to them that are bitten by a mad dog, whereby they are afraid of water.

Hypochondriall parts, be the flanks or ſoft parts under the ſhort ribs.

I

Iliacke paſſion, the wrings and torments of the upper ſmall guts, occaſioned by wind or ſharpe humors. Some improperly call it the collicke of the ſtomacke.

Imbibition, a drinking or receiving of any liquor into a thing: as when drougs lie ſteeped therein untill they be throughly ſoaked therewith.

Impoſtumes properly be collections or gatherings of wind and humours eſpecially betweene parts of the bodie, wherupon there appeareth a riſing or ſwelling, and in time they become corrupt and doe rankle, unleſſe by ſome meanes they be either drawn away or diſperſed. Some tearme them wens, howbeit, the word is taken for inflammations and biles.

To *Incorporat*, is to mix and unite well together.

To *Incraſsate*, is to make thicke.

Indigeſtion, *i.* want of concoction and digeſtion, by which meanes many crudities and raw humors are engendered, and by conſequence abundance of rheumes.

Inflation, i. ſwelling or puffing up with wind.

Infrangible, i. that cannot be broken.

Infuſion ſignifieth the conveighance of ſome medicinable liquour into the bodie by clyſtre or other inſtrument. It importeth alſo the ſteeping of drougs in a convenient liquor: and the liquor it ſelfe, when it is ſtrained from the reſt.

Ingredients, be thoſe ſimples that goe unto the making of any medicine compound.

Iniection, is the conveighance of any liquid medicine by ſyringe or ſuch like inſtrument into any part of the bodie or hollow and fiſtulous ulcer.

Inſects, little vermine or ſmall creatures, which have (as it were) a cut or diviſion betweene their heads and bodies, as Piſmires, Flies, Graſhoppers, under which are comprehended Earthwormes, Caterpillers, &c.

Inſeſsions be bathing tubs or veſſels halfe full; wherin the patient may ſit up to the middle or above in ſome convenient decoction.

Intermittent feaver, are thoſe which come by fits, and yeeld ſome reſt betweene whiles.

Inunction, i. annointing.

Iulebs or *Iuleps*, be drinkes given commonly as preparatives for to open the paſſages of the inward parts, and to prepare the humours for a purgation, made either of ſome ſtilled waters and ſyrrups mixed together, or of a decoction ſweetened with honey or ſugar, or els mingled with ſyrrups.

K

Kings evill, is the hard ſwelling of the Glandules or Kernels commonly about the necke: they be called alſo Scrophules.

L

Lachrymal, is the corner of the eye wherin the teares appeare firſt, and thereof it taketh the name.

Laſsitude, is wearineſſe or unluſtineſſe.

Lavature, *Lotion*, or *Loture*, is a liquour to bath or waſh withall: likewiſe to cleanſe and mundifie any part.

Ligula, *Lingua*, or *Lingula*, a ſmall meaſure among the Romanes, both of liquour and drie things, containing the fourth part of Cyathus, to wit, three drams and one ſcriptule or ſcruple, ſomewhat under halfe an ounce, and may goe well for our ſpoonefull.

A *Liniment* is thicker than oyle, and thinner than an ointment, it may be taken for a thinner kind of ointment.

Lobes and fibres are the lappets and extreame parts of the liver, with the maiſter veines growing thereto.

Locall medicines, be thoſe which are appropriat for the forehead, *Errhine* or *Naſal* for the noſthrils, &c. or to be applied outwardly as ointments, which are not to be uſed before generall or univerſall means by evacuation.

Loch or *Lohoch*, is a medicine more liquid than an electuarie, appropriat for the lungs and windpipe, and is to bee licked and let goe downe leiſurely.

Longaon, is the nethermoſt gut reaching to the very ſeat or the fundament.

Luted,

Luted, *i.* close stopped with cley, dough, or such like.

M

Maturatives be medicines that help to ripen any swelling impostume, bile, or botch.

Maturitie, is the ripenesse thereof.

Membranes, be fine skins which enwrap other parts, as the brains, eyes, and muscles of the flesh.

Metrenchyte, an instrument serving to infuse or inject a liquid medicine into the matrice of a woman, in manner of clystre.

Mitigatives, be such remedies as doe assuage paine.

Mna or *Mina*, was a Roman weight, which poised twentie ounces, that is to say, the ordinarie pound, called Libra or Pondo, & two third parts: for the common Libra called Medica, weighed twelve ounces, so that Mina seemed to answere unto the measure Sextarius.

Mollitive. See *Emollitives*.

Mordicative, is biting and stinging, as Senvie seed.

Mucilage, is a slimie liquor drawne from some roots or seeds, as from the marsh Mallow or Althea root, the seed of Psillium or Fleawort and others.

Muscles be the fleshie parts of the bodie, contained within their severall membranes or skins.

N

Narcoticke medicines, bee those that benum and stupifie with their coldnesse, as Opium, Hemlocke, and such like.

Nasals be Nose-tents. See *Errhina*.

Nerves, *i.* Sinewes.

Nodosities, hard knubs and knots growing upon the joints in old gouts, and in other parts.

O

Obolus, halfe a scriptule, or the sixt part of a dram.

Obstructions, *i.* Stoppings.

Opiats, were properly at the first such electuaries or confections, which had a good quantitie of Opium, *i.* the juice of Poppie in them, such as Philonium and Requies, which were devised to mittigat intollerable paine, and to bring the patient to sleepe: howbeit, in these daies all electuaries, even cordials, in a liquid forme be called Opiats, although there be not one grain of Opium in them.

Opilation. See *Obstruction*.

Orthopnoicks, are those that have the disease Orthopnœa, which is a difficultie of drawing their wind, unlesse they sit upright.

Osses, be words cast forth at unwares, presaging somewhat.

Otenchyte, an instrument, devised for to infuse or poure some medicinable liquor into the eares.

Oxycrate, a mixture of water and vinegre together.

P

To *Palliat*, *i.* to cover. And such cures be called Palliative, which search not to the root and cause, but give a shew only of cure; as when a sore is healed up aloft, and yet festereth underneath: and so sweet Pomanders doe palliat a stinking breath, occasioned by a corrupt stomack or diseased lungs, and such like.

Paradoxes, strange opinions.

Pectorals, *i.* such medicines as bee fit for the breast and lungs.

Pellicles. See *Membranes*.

Penetrative, *i.* Percing.

Periodicall, such agues bee called, as returne at their iust course from day to day, every third fourth or fift day, &c.

Peripneumonie, is the inflammation of the lungs.

Pessarie, is a devise made like a finger or suppositorie, to be put up into the natural parts of a woman.

Phlebotomie, *i.* bloud-letting, or opening of a veine by incision or pricke.

Phthysicke, to speake properly, is the consumption of the bodie occasioned by the fault of exulcerat and putrified lungs. But *Plinie* otherwhiles seemeth to take it for any other consumption.

Pomona, a devised goddesse among the Painims, of apples and such fruits.

Prodigies be straunge sights and wonderfull tokens, presaging some fearefull thing to come.

Propinquitie, neareneſse or affinitie.

Proscription, was a kind of outlawing and depriving a man of the protection of the state, with

with confiſcation of his lands and goods.

Propagat, to grow and encreaſe, after the manner of Vine braunches, which being drawn along in the ground from the motherſtock doe take root.

Propitious, *i.* gracious and mercifull.

Proximitie, neere neighbourhood or reſemblance.

Ptiſane, the decoction of husked Batley: a grewell made therewith, or the creame thereof.

Pulpous, *i.* full of pulpe, or reſembling pulpe, which is the ſoft ſubſtance in Apples or ſuch fruits, anſwerable to the fleſh in living bodies.

Purulent, yeelding filth and Attyr.

Putrefactive, ſuch venomous medicines or humors, as do corrupt and putrifie the part of the bodie which they poſſeſſe.

Q

Qvindecemviri, were certain officers, fifteen in number, joined in one commiſſion.

R

Receptorie, a veſſell ſtanding underneath, readie to receive that which droppeth and deſtilleth from ſomething above it.

Reciprocall, going and comming, as the tides of the ſea ebbing and flowing.

To *Rectifie*, *i.* to ſet ſtreight, reforme, or amend.

Repercuſsive, *i.* driving or ſmiting backe.

Reſidence, *i.* the ſetling toward the bottome, as in urine.

Retentive facultie, *i.* the naturall power that ech part or member of the bodie hath to hold that which is committed unto it, the due time, as the ſtomacke, meat; the bladder, urine, &c.

Reverberation, *i.* rebounding or ſtriking back.

Rhagadies, be properly the chaps in the fundament or ſeat.

Rubified, *i.* made red, as when by application of muſtard plaſtres, called Sinapiſmes; or beating a part that is benummed with Nettles, it recovereth a freſh colour againe, whereupon ſuch plaſtres be called Rubificative, and the operation is named by the Greekes Phœnigmos.

Rupture, the diſeaſe of burſting, as when the guts or other parts fall downe into the bag of the cods.

S

Salivation, is a drawing of humours to the mouth, and a deliverie of them from thence in manner of ſpittle.

Sarcling is the bating of roots, by ridding away the earth and weeds from about them, that did clog them.

Scarification, is a kind of pouncing or opening of the skin by way of inciſion ſlightly, with the fleame or launcet, either to give ſome iſſue for the bloud & humors to paſſe forth, or to prepare a place for the cupping-glaſſe to extract more.

Schirre, is a hard ſwelling almoſt ſenceleſſe.

Scriptule, or *Scruple*, is foure and twentie grains weight, or the third part of a dram.

Scrophules. See *Kings evill*.

Seat, is the circumference or compaſſe about the tuill or fundament.

Secundine, *i.* the afterbirth that infolded the infant within the mothers wombe.

Seege, a ſtoole of eaſement, whereupon we ſit to diſcharge the ordure and excrements of the guts.

Seroſities, or *Serous humours*, bee the thinner parts of the maſſe of bloud, anſwering to the whey in milke, ſuch as we ſee to floate upon bloud that hath run out of a veine.

Sextarius, a meaſure among the Romanes, whereof ſix goe to their Congius, whereupon it tooke that name: it containeth two hemines, and is ſomewhat leſſe than a wine quart with us, it beareth twentie ounces.

Sinapiſme, a practiſe by a plaſtre of muſtard ſeed, and ſuch like, to revive a place in manner mortified, and to draw freſh humors and colour to it.

Solſtice, *i.* the Sunneſtead, as well in Winter as Summer, when hee is come to his utmoſt points North and South, but uſually it is put for Midſummer onely.

Sophiſticated, *i.* falſified and made corrupt, howbeit, going for the right. Thus drougs and gems are many times thruſt upon us.

Spaſmes, be painefull crampes or pluckings of the ſinewes and cords of the Muſcles.

Spaſmaticke, are ſuch as be thus plucked.

Species, be either the ſimple ingredients into a compoſition, or els the bare pouders mingled together, readie to be reduced into an electuarie liquid, or Tables.

Speculative knowledge, or *Speculation*, is the inſight into a thing by reading only and contemplation

templation, without practise & experience.

Sperme, is naturall seed.

Spondyles, be the turning joynts of the chine or backbone.

Stomachicall flux, is the same that Cœliaca passio. See *Cœliaci*.

Stomaticall medecins, be such as are appropriat for the diseases incident to the mouth, and the parts adjoyning.

Stypticke, be such things as by a certaine harsh tast, doe shew that they be astringent, as medlars, and alumne, which thereupon is named *Stypteria*, and such like.

Succedan, that drug which may be used for default of another. The Apothecaries call such, *Quid pro quo*.

Suffusion. See *Cataract*.

Suffumigation, is the smoke that is received into the body from under a stoole, for the diseases of the guts, fundament, or matrice.

Suppuration, is when a bile or impostume gathereth to an head and must be broken.

Sympathie, *i*. a fellow-feeling, used in *Plinie* for the agreement or amitie naturall in divers senslesse things, as betweene yron and the loadstone.

Symptome, an accident accompanying sicknes, as head-ach the ague; stitch, shortnesse of wind; spitting bloud, cough, and ague, the pleurisie.

Syringe, an instrument in manner of a pipe to inject a medicinable liquor into the bladder.

T

TEllus, the Earth.

Tenacitie, clammines, such as is in glew, birdlime, and bitumen.

Theoricke, or *Theoretique*, contemplative knowledge without action and practise.

Tinesme, an inordinat desire to the stoole without doing any thing to the purpose.

Tonsils. See *Amygdals*.

Transparent, *i*. cleare and bright throughout; as crystall, amber, aire, and water.

Transvasation, *i*. the pouring of liquor out of one vessell into another.

Triviall, *i*. vulgar, common, and of base reckoning.

Triumvirat, the Tripartite dominion of *Antonie*, *Octavius*, and *Lepidus*, when they held all the world in their hands, each one their third part.

Trochisques, or *Tросques*, be little cakes or roundles, into which divers things medicinable are reduced for to be kept the better, and to be readie at hand when they shall be used.

Tuil, the same that the Fundement or neathermost gut.

V

VEgetative, that power in nature which God hath given to creatures, wherby they live, are nourished, and grow.

Ventositie, windinesse.

Vicinitie, neareneſse, or neighbourhood.

Victoriat, a silver coine in Rome, Halfe a denarius, so called becausе it had the image of Victorie stamped on the one side: it is somewhat under our groat.

Vnction, annointing.

Vnguent, an ointment.

Vreters, bee the passages or conduits whereby the water or urine passeth from the kidnies into the bladder.

Vulnerarie, *i*. belonging to a wound; as Sanicle is a vulnerarie hearb, and *Machaon* was a vulnerarie Physician.

THE XIX. BOOKE OF THE HISTORIE OF NATVRE, WRITTEN BY C. PLINIVS SECVNDVS.

The Proëme.

TReated we have in the former booke, of the ſtars and ſignes above, which give us intelligence as well of the ſeaſons, as the diſpoſition of the weather to come: and that in plain and eaſie manner, by ſo evident and undoubted demonſtrations alſo, as may content the meane capacitie of the unskilfull and ignorant. And verily, if wee will rightly weigh and conſider the thing, we ſhall find and underſtand, That our countrie farmes and villages ſtand us in as good ſteed to know the inclination of the heavens and ſtars, as the skill of Aſtronomie ſerveth our turnes for good Husbandrie. Theſe points now being well and throughly learned, many have been of opinion, That the knowledge of gardens & the care thereto belonging, ſhould by good right follow next. Howbeit, I for my part am of this mind, that there be other matters concerning Agriculture, deſerve to be handeled, before we leape thus ſoone to gardening. And here I cannot chuſe but marvell much at ſome men, who making ſuch profeſſion of learning, and namely, in the skill and ſcience of Agriculture, as they have done; yea, and ſeeking thereby to win all their credit and name of erudition and litterature; have notwithſtanding omitted many things requiſit thereunto, without any mention made, or one word ſpoken of ſo many hearbes and ſimples which either come up of themſelves, or grow by meanes of mans hand: conſidering that the moſt part of them are in greater price and reputation, yea, and in more uſe and requeſt far, for the maintenance of this our life, than either corne or pulſe, or any fruits of the earth whatſoever.

And to begin firſt at thoſe that are knowne commodities, and ſo notorious, as that the uſe thereof not onely reacheth all over the maine and continent, but extendeth alſo to the very ſeas, and overſpreadeth them: What ſay we to Line or Flax, ſo commonly ſowed as it is? yet may it not be raunged either among the fruits of the field, or hearbes of the garden. But what region (I pray you) or part of the earth is without it? and what is there ſo neceſſarie for this life of ours in all reſpects? Againe, is there any thing in the whole world more wonderfull and miraculous, than that there ſhould be an hearbe found of this vertue and propertie, as to bring Ægypt and Italie together? inſomuch, as Galerius, Lord Deputie in Ægypt under the Romanes, was knowne to ſet ſaile from the firth of Meſſina in the ſtreights of Sicilie, and in ſeven daies to arrive at Alexandria: Babilius alſo Governour there likewiſe, in ſix; and that by the meanes of the ſaid hearbe? Moreover, what ſay you to this, which was ſeene no longer ſince than the Summer paſt; when Valerius Marianus, a Senatour of Rome, and late Lord Pretour, embarked and tooke ſhip at Puteoli, and in nine daies ſailed to the ſaid Alexandria, and yet he had but a very mild and ſtill wind to helpe him in that voiage? Is not this a ſtrange and ſoveraigne hearbe thinke you, that in a ſeven-night ſpace can fetch Gades from as far as the ſtreights of Gilbretar or Hercules pillars, into the harbour of Oſtia in Italie? can ſhew (I ſay) the kingdome of Catalogne in Spain before the ſaid port-town in foure daies, Provance in three, and Barbarie in twaine? For C. Flaccus, lieutenant under Vibius Criſpus the Pro-conſull, did as much as I ſpeake of, and that with no great forewind, but a moſt gentle and mild gale. Oh the audacious boldneſſe of this world, ſo raſh, ſo full of ſin and wickednesſe, that man ſhould ſow and cheriſh any ſuch thing, as might receive and ſwallow the winds, ſtormes, and tempeſts; as if the float and tide alone were not ſufficient to carie ſo prowd a creature! But now are we growne moreover to this paſſe, that ſailes bigger than the ſhips themſelves, will not ſerve our turnes. For albeit one maſt be ſufficient to carie the biggeſt croſſe-yard that can be deviſed, yet are not wee content with a ſingle

maine saile thereupon, unlesse we set up saile upon saile, top and top-gallant: unlesse (I say) wee have fore- G
sailes and sprit-sailes in the Prow, misns also hoised up and displaied in the poupe; besides other trinkets and more cloth still: and all to set us more forward upon our death, and to hasten our end. Finally, is there ought againe so admirable, as that of so small a graine as is the Line-seed, there should grow that which is able to carrie too and fro in a moment, this round globe of the earth; the same being so slender a stalke as it is, and not growing high from the ground? considering withall, that twisted it is not entire and whole in the stem: but before it can bee occupied, it must bee watered, dried, braked, tew-tawed; and with much labour driven and reduced in the end to bee as soft and tender as wooll: and all to doe violence to nature and mankind most audaciously even in the highest degree, in such sort, as a man is not able to proceed so farre in execration as is due unto this Invention. The first deviser whereof I have H
inveighed against in convenient place elsewhere, and not without desert: as who could not bee content, that a man should die upon the land, but he must perish upon the sea, to feed hadockes there, without the honour of sepulture. In the booke but next before this, I gave warning and advertised men, That for to enjoy corne and other victuals necessarie for this life in sufficance and plentie, wee should beware of wind and raine. And now behold, man is so wicked and ungracious, his wit so inventive, that he will be sowing, tending, and plucking that with his own hand, which cals for nothing else at sea but Wind; and never rests till Burning bee come. See moreover how well this unhappie hand of his speeds, for there is not a plant againe commeth up sooner, or thriveth faster than this Flax. And to conclude, that wee may know how Nature her selfe is nothing well pleased therewith, and that it groweth maugre her will, It burnes the field wherein it is sowed; it eateth out the heart of the ground, and maketh it worse, whersoever it comes: this is all the good it doth upon a land. I

Chap. I.

The manner of sowing Line or Flax: the sundrie kinds thereof. The order how to dresse it. Also of Napkins and other Naperie. Of Flax and Linnen that will not burne in the fire. And when the Theatres or Shew-places at Rome were first encourtained.

LIne-seed loveth gravelly or sandie grounds passing well, and commonly is sowed with one tilth and no more: yet is there nothing maketh more hast to be above ground, or sooner commeth to maturitie. Being sowne in Spring, it is pluckt in Summer: See how *injurious still it is to the earth even this way also! Well, say that the Ægpytians in some sort may be excused, for sowing it as they do, and making saile-cloth thereof; in regard of the necessarie trafficke, they have into Arabia and India, for to fetch in the commodities of those countries; what need or reason I pray you hath Fraunce so to doe? Can the Gaules be sorted in the same raunge with the Ægyptians? Whether would they goe? Is it not sufficient that they see the mightie mountaines standing just betweene them and the Mediterranean sea? Will not this serve to keep them from Navigation, that on the huge Ocean side, they can discover nothing but the vast elements of Water and Aire together? Howbeit, for all this restraint, the Cadurci, Caletes, Rutene, and Bituriges; the Morini also who are supposed to be the farthest people inhabiting our continent, yea, and throughout all parts of Fraunce they weave line and make sailes therof. And now adaies also the Flemmings and Hollanders dwelling beyond the Rhene (I meane those auncient enemies to the State of our Empire) do the like: *insomuch, as the women there cannot devise to goe more rich and costly in their apparell, than to weare fine Linnen. The observation whereof putteth me in mind of a thing, that *M. Varro* doth report of the whole race and familie of the Serrani: in which house this order was precisely kept, That there was not a woman among them knowne to weare any Linnen about her, not so much as in a smocke next her bare skin. Now in Germanie, the spinners and weavers of Linnen, doe all their worke in shrouds, caves, and vaults, buried (as it were) under the ground: so doe they also in Italie and that part of Lumbardie that lieth betweene the Po and Ticinus, to wit, in the *countrey Aliana; where (after the Setabines in Castile, which is the best) there is very fine workmanship of Linnen cloth, and may deserve the third place for goodnesse, throughout all Europe. For the Retovines, bordering hard upon the foresaid Allianes, and the Faventines who inhabite the broad port-way Æmilia, are to bee raun-*

K L M

*For that so quickly it robbeth her of moisture.

*It seemeth that fine Holland cloth and Cambrick was in request by *Plinies* time.

**Regione Aliana.* Turneb.

ged

A ged in a ſecond degree and next to the Setabines for the fine Linnen which they make. And in very truth, this Faventine cloth is alwaies farre whiter than the Allian, which is ordinarily brown when it is new woven, and before it be bleached. Like as the Retovine is exceeding fine and thick woven withall, and beſides, not inferior in whiteneſſe to the Faventine; howbeit, no nap or downe it carieth, a thing which as there be ſome who doe greatly praiſe and like, ſo there bee others againe diſcommend and diſlike as much. As touching the thred it ſelfe that they make of their Flax, it is more even (if evener may be) than that which the Spider ſpinneth; ſo nervous alſo and ſtrong withall, that if a man liſt to make triall thereof with his teeth, it will give a twang and ring againe like a Lute-ſtring: and therefore it carieth a double price to other. As touching the Spaniſh Flax, and namely, that which Aragon and Cartalogna dooth yeeld, it is paſſing faire and
B white, by reaſon of a certain brook or running water paſſing under Tarracon, wherein it is watered: the nature whereof is to give it a ſingular brightnes above the reſt. Wonderous fine it is, and runneth into a daintie ſmall thread: for there firſt was deviſed the fine Cypres or Lawne, and the curtaines thereof. It is not long ago, ſince out of the ſame parts of high Spain, there was brought into Italie the Flax of Zoela, moſt commodious and meet for hunters to make great nets and toile. A maritime citie this Zoela is, in Gallitia, ſituat neare the Ocean. There is excellent good Line alſo to bee found at Cumes in Campaine within Italie, which ſerveth very well for ſnares and ſmall nets to take fiſhes, and catch birds with. The ſame alſo yeeldeth matter and ſtuffe for the great cord-nets aboveſaid. For wote well this, that Flax fitteth our turnes, as well to ſnare and entrap all other beaſts, as it doth to endaunger our owne ſelves [upon the ſea.] But of all o-
C thers, the toile made of Cumes Flaxen cords, are ſo ſtrong, that the wild Bore falling into it, will bee caught: and no marvaile, for theſe kind of nets will checke the very edge of a ſword or ſuch like weapon. I my ſelfe have ſeene ſo fine and ſmall a thred, that a whole net knit thereof, together with the cords and ſtrings called Courants, running along the edges to draw it in and let it out, would paſſe all through the ring of a mans finger. I have knowne one man alſo carie ſo many of them (eaſily) as would goe about and compaſſe a whole forreſt. But that is not the greateſt wonder of them: for more than ſo, every one of thoſe threds that went to the making of the maſhes, was twiſted 150 double: and even of late daies, *Iulius Lupus*, who died lord Deputie or Governour of Ægypt, had ſuch. This may well ſeeme a marveile incredible to thoſe who neither knew nor ſaw the net-worke Habergeon or Curet of *Amaſis*, a king ſometime of Ægypt, which
D was ſhewed of late daies within the temple of *Minerva*, in the Iſle of the Rhodians; every thred whereof caried a twiſt *three hundred ſixtie five double. Certes, *Mutianus*, a man of good credit (as who had been thrice Conſull of Rome) hath related ſo much at Rome upon his owne knowledge: for whereas there remained yet certaine ſmall reliques and little peeces thereof, it was his hap of late to meet with ſome of them, and by his owne triall to find that true, which had been reported by others. And verily, great pitie it is, that ſuch an excellent, rich, and rare peece of work (as it was) ſhould thus come to nothing, by mens injurious handling of it, raveling out the threds as they have done, for to ſee the proofe of the thing.

* According to the daies of the yeare.

But to returne againe to our Flax of Italie. That which groweth in the Pelignians countrey, is at this day in great account and requeſt: howbeit, none uſe it but the Fullers. There is not a whi-
E ter Flax to be found, & indeed reſembling Wooll nearer than this Flax. Like as, for quilts, ticks, and mattraſſes, the Flax of the Cadurci in Fraunce had no fellow: for ſurely the invention thereof, as alſo of flockes to ſtuffe them with, came out of Fraunce. As for us here in Italie, even as our manner was in old time to lie and ſleep upon ſtraw-beds & chaffey-couches, ſo at this day we uſe to call our pailets ſtill by the name of Stramenta. The Line or Flax of Ægypt is nothing ſtrong, howbeit the people there doe raiſe exceeding great gaine and profit thereof. And foure diſtinct kinds thereof are knowne, according to the names of the ſundrie countries where they grow, to wit, Taniticum, Peluſiacum, Buticum, and Tentyriticum.

Moreover, in the higher parts of Ægypt which bend toward Arabia, there groweth a certain ſhrub or buſh carrying cotton, which ſome call Goſſypium, others * Xylon, and the linnen ther-
F of made they therefore call * Xylina. This plant is but ſmall, and bringeth forth a fruit reſembling the bearded nut or filberd; out of the inner ſhell or huske whereof [called *Bombyx] there breaketh forth a cotton like unto down, ſo eaſie to be ſpun: and there is no flax in the world comparable to it for whiteneſſe and ſoftneſſe. Of this cotton, the Ægyptian prieſts were wont to wear their fine ſurpleſſes, and they tooke a ſingular delight therein. A fourth kind of linnen there is,

* Cotton or Bombace.
* Linſey-Woolſey, or our Fuſtians rather.
* Hereupon Cotton is called Bombace.

called Orchomenium; it commeth from a certaine fennie reed growing in mariſhes, I meane the tender muchets or chats thereof. G

In Aſia they have a certaine kind of broome, the ſtalke and braunches whereof they water and leave in ſteepe ten daies togither, and thereof make thread, paſſing good for to be twiſted and knit into fiſher-nets, for they will abide the water very well, and endure without rotting. The Æthiopians and Indians both, find a ſtuffe in manner of Line or cotton in ſome apples or ſuch like fruit: and the Arabians meet with the like in gourds, growing as I have before ſaid upon trees.

To come againe to our countrey Line or Flax within Italy, we goe by two ſignes, and know thereby when it is ripe and readie to be gathered; to wit, either by the ſwelling of the ſeed, or the colour of the plant it ſelfe, leafe and ſtalke enclining to yellow. Then is it plucked up and bound H into certaine bunches as much as handfuls: which done, they are hung up to drie in the ſun one day, with their heeles or roots upward: the morrow after, they be turned quite contrarie, and ſo for five daies after, they hang with the foreſaid roots downward, that the ſeed may fall down from their heads into the mids of every bunch or bundle aforeſaid: for the ſeed thereof is medicinable and of effectuall operation in Phyſicke: yea and the rurall peaſants in Lombardie and Piemont beyond the Po, uſe to make thereof a good countrey meat of a moſt ſweet and pleaſant taſt: but now for this good while, that kind of meat or bread is made onely for to be employed in their ſacrifices to the gods. Then after wheat harveſt, the ſtems or ſtalkes thereof are laid in ſome water that is warme with the Suns heat, charged with ſtones or other weights thereupon, that they may be borne downe and ſinke to the botome: for there is not a thing beſides lighter I than Line, or loveth better to ſwim. When they be ſufficiently watered (which you ſhall know by the skin or rind thereof if it be looſe and readie to depart from the towie ſubſtance of the ſtem) then muſt the foreſaid javels or ſtalks be hung out a ſecond time to be dried in the ſun, with their heads and heeles one while up and another while downe, as before. After they be well dried, they are to be beaten and punned in a great ſtone mortar, or upon a ſtone floore, with an hurden mallet or tow-beetle made for the purpoſe. Now that part thereof which is utmoſt and next to the pill or rind, is called Tow or Hurds, and it is the worſt of the Line or Flax, good for little or nothing but to make lampe-match or candle-wicke: and yet the ſame muſt bee better kembed with hetchell teeth of yron, untill it bee cleanſed from all the groſſe barke and rind among. As for the good Flax indeed, which is the teere or marrow as it were within of the Line, there bee K diverſe and ſundrie ſorts and degrees of it, diſtinct according either to the whiteneſſe or ſoftneſſe thereof. And the ſpinning of this fine Flax (I may tell you) is ſo cleane a worke, that it will become a man ywis to lay his fingers to it. But what ſhall bee done with all the hard refuſe, the long buns of the ſtalkes, the ſhort ſhuds or ſhives which are either driven from the reſt in the knocking, or parted in the hetchelling? marry they will ſerve very well to heat ovens and furnaces, or to maintaine fire under kills and leads. And here there is a prettie cunning and skill in the hetchelling and diſpenſing of Flax to the proofe; for if the Line bee good and well ordered, every fiftie pounds of it in bunches or bundles aforeſaid, muſt yeeld fifteene ordinarily of tried and carded Flax. Moreover, when it is ſpun into thread, it muſt be poliſhed againe and whiteL ned in water, with much punning and knocking upon a ſtone togither with the water. And yet there is no end, for after it is woven to cloath, it ought to bee followed and beaten a third time with good club-headed cudgels: in ſuch ſort, as the more injurie that is done unto it, the better it is.

Furthermore, there is a kind of Line found out which will not conſume in the fire: this in Italie they call Quicke-line: and I my ſelfe have ſeen table-cloaths, towels, and napkins therof, which being taken foule from the bourd at a great feaſt, have been caſt into the fire, and there they burned before our face upon the hearth; by which meanes they became better ſcoured, and looked fairer and brighter a hundred times, than if they had been rinſed and waſhed in water; and yet no part of their ſubſtance, but the filth only, was burnt away. At the royall obſequies and funerals of KK. the manner was to wind and lap the corps within a ſheet of this cloth, of purpoſe to ſeM parate the cinders comming of the bodie, from other aſhes [of the ſweet wood that was burnt therewith.] This manner of Line groweth in the deſerts of India, where no rain falls, where the countrey is all parched and burnt with the Sunne, among the fell dragons and hideous ſerpents. Thus it is enured there to live burning; which is the reaſon, that ever after it will abide the

fire.

A fire. Geason it is to be found, and as hard to be woven, so short and small it is. Howsoever otherwise it be naturally of colour reddish, yet by the fire it getteth a shining glosse and bright hew. They that can come by it and meet withall, esteeme it as precious as the best orient pearles. In Greeke they call this Line, Asbestinum, according to the nature and propertie that it hath, Not to consume with burning. Over and besides, *Anaxilaus* saith, That if a man would cut down or fall a tree by stealth and in secret, let him compasse the body thereof with a sheet of this linnen, he may hew as long as he will at it, and all the strokes that he giveth will be so drowned, that they shall not be heard againe. To conclude, in all these respects abovesaid, this Line may well be counted for the principall and best that is in the whole world.

The next to it in goodnesse, is the Line called Byssus: the fine Lawne or Tiffanie whereof our
B wives and dames at home set so much store by for to trim and decke themselves: it groweth in Achaia within the territorie about Elis: and I find, that in old time it was sold as deare as gold, for a *scruple thereof was commonly exchaunged for *foure Deniers Romane.

The lint or nappie downe which linnen cloth beareth in manner of a soft cotton, especially such as commeth of ship sailes that have ben at sea, is of great use in Physicke. *The ashes also made thereof, be counted a good Succedane of Spodium, and for their efficacie may go for it. Moreover, there is a kind of Poppies much sought after for blaunching and bleaching of linnen cloths; for being skoured therewith, it is wonderfull how white and pure they will looke. And yet for all the beautie that consisteth in that colour, people are grown to this disorder & vain enormitie, that they have assayed to staine and die their linnen and naperie into other colours, as well
C as their woollen cloth. Which practise was first seene in the Armada or fleet of K. *Alexander* the Great, upon the great river Indus, at what time as his captaines and Admirals in a certaine skirmish that they made with the Indians, chaunged the armes and ensigns of their ships: wherat the inhabitants (beeing upon the shore and strond) were astonied to see their sailes and streamers painted with divers colours waving in the wind. Semblably, the Sailes of that ship were died purple, wherein *M. Antonius* togither with *Cleopatra* came to Actium, and in which they fled both from thence and escaped. And in deed heretofore a red purple banner erected on the top of the mast, was the badge or ensigne of the royall Admirall ship: but afterwards they began at Rome to encourtaine their Theatre with such veiles died in colours, onely for shade: an invention devised by *Q. Catulus* at what time as hee dedicated the temple of the Capitoll. In
D processe of time, *Lentulus Spinter* (by report) was the first man that in the solemnitie of the games and plaies Apollinare, drew fine courtains over the great Amphitheatre at Rome: howbeit not long after, *Cæsar* Dictatour caused the grand Forum or Common-place at Rome to be covered all over with such rich courtains; yea and the high faire street called Sacra, to be hanged on both sides from his owne dwelling house to the very Capitoll cliffe: which magnificent and sumptuous sight, was more wondered at and seene with greater admiration, than the brave shew and Tourney that he set out at the same time of Sword-players at sharpe and to the utterance. Then followed *Marcellus* also the sonne of *Octavia*, sister to the Emperour *Augustus*, who in his owne Ædileship & in the tenth Consulship of his uncle *Augustus* beforesaid, upon the Calends or first day of August that yeare, caused the Romane Forum to be drawn all over and shadowed
E with the like courtains, although hee represented at that time no solemnitie at all of games and plaies: and this he did onely, that they who came to plead at the barre, might stand under shade more holesomely. Lord, what a chaunge was here at Rome since the daies of *Cato* the Censor, who thought it meet and requisit, yea and gave advise that the said Forum or great Hall of common Pleas should be paved and laid all over with caltraps under foot, To keep our Lawyers and busie pleaders from thence. Of late daies there were seene in the Amphitheatres of Emperour *Nero*, traverses drawne upon cords and ropes, with fine courtains of blew azure colour like the skie, and those beset with starrs; where the very floore of the ground under mens feet, was coloured red. And wherefore serve these in cloister-courts and walkes now, but to keepe the mosse forsooth upon the ground, or rather the fine fret-worke in pavements, from Sun-burning? But for
F all these paintings and rich dyes, yet when all is done, the white linnen held the owne still & was highly esteemed above all colours. And no doubt in great price such cloth was in the time of the Trojane war: and in good faith I see no reason why it should not be as well in bloodie battails as at broken shipwracks. Howbeit *Homer* testifieth, that few there were who went to the wars with linnen habergeons or curets: but it should seem that the Poet (as the better learned expositors do interpret)

* 24 graines.
i. about three halfe-pence the graine, and better.
*Hereof were made ξυλὶ μωμὶ, wherof *Galen* writeth 3. κῶμ. with which lint he cured *Heraclides* and staunched his bleeding.

terpret) meant, That ſhip-tackling, ſailes, cords, and ropes, were made of this Line, ſpeaking as he doth of * Sparta, whereby hee underſtandeth in deed Sata, *i.* cordage of ſowne Line or garden Flax. G

* Called by *Pacuvius, Serilia*, as *Feſtus* noteth.

CHAP. II.

The nature of Spart or Spaniſh broome: the manner of handling and dreſſing it: when it was firſt uſed in cordage: what plants there be that live and grow without root.

SPart verily was not in uſe and requeſt for many hundred yeares after, neither was it knowne before the firſt voyage and expedition that the Carthaginians made in warlike manner into Spaine. An hearb this is alſo, growing of it ſelfe without ſetting or ſowing (which in deed it cannot abide.) Full well and properly it mought be called, the ruſh of a dry and leane ground, and a very defect or imperfection appropriate to that countrey alone of Spaine: for, to ſay a truth, it is the fault and badneſſe of the ſoile in the higheſt degree, that breedeth it; and where it commeth up, nothing elſe can be ſowed and ſet, or will grow at all. That in Africke or Barbarie is very ſmall, and good for nothing. In the territorie of new Carthage or Cartagena (which is in the higher part of Spaine) it groweth much: howbeit all that tract is not given to breed it, but looke where it commeth up, you ſhall ſee whole mountains all over-ſpread and covered with it. Hereof the ruſticall peaſants make their mattraces and beds; this is their fewell wherewith they keepe fires; of it they make their torches and links to give them light; with it they are commonly ſhod; and the poore ſhepheards cloath themſelves therewith. Howbeit, hurtfull is this plant unto cattaile, unleſſe it be the tender tops and crops of the braunches, which they may brouſe and eat without harme. For other uſes, when the Spaniards would plucke it up, they have much adoe withall, and a great toile about it; for their legs muſt be well booted as it were with grieves; their hands covered with thicke hedging gloves, as gantlets: and being thus armed at all points, yet they lie tugging at it, pulling, writhing, and wreſting the ſame with hookes and crooks either of bone or wood, untill they have their will of it. Come they about this worke in winter time, it is in manner unpoſſible to get it up: but from the Ides [*i.* the mids] of May unto mid-Iune, it is very tractable: for this is the time and ſeaſon when it is ripe, and then commonly they gather it for their ordinarie uſes before-named. Being once pulled and ſorted, the good from the bad, it is made up into bundles and faggots with the life ſtill in it, and ſo piled on a heape for the firſt two daies; the third day they unbind it, lay it looſe and ſcattering in the Sun for to be dried: which done, they make it up againe into faggots, and ſo bring it in and lay it up within-houſe. After all this, they ſteepe it in ſea water (for that is beſt) or els in freſh, for want of the other. After this watering, it muſt be dried in the Sun, and then ſteeped in water a ſecond time: but if a man have urgent occaſion to uſe it preſently out of hand, he muſt put it in a great tub or bathing veſſell, and let it ſoke there in hot water a time. Now if when it is dried againe, it be ſtiffe and will ſtand alone, they take it for a ſure ſigne that it is ſufficiently watered, and hath that which it ſhould have. This is a very neare and readie way, and ſaveth them much labour. Thus being prepared one of theſe two waies, it ought to be brayed and beaten before it will ſerve the turne; and then no cordage in the world is better than that which is made of it, nor laſteth ſo well within the water and the ſea eſpecially, for it will never be done. For drie worke, I confeſſe, and out of the water, the gables and ropes made of hempe are better; but Spart wrought into cordage will live and receive nouriſhment within the water, drinking now the full as it were to make amends for that thirſt which it had in the native place where it firſt grew. Of this nature is Spart beſides, that if the ropes made thereof be worne, and (with much occupying) out of repaire, a little thing will mend and refreſh them, yea & make them as good as ever they were; for how old ſoever it be, yet will it be wrought very well againe with ſome new among. A wonderfull thing it is to conſider and looke into the nature of this hearbe, and namely, how much it is uſed in all countries, what in cables and other ſhip-tackling, what in ropes for Maſons and Carpenters, and in a thouſand neceſſities of this our life. And yet ſee! the place which furniſheth all this ſtore, lying along the coaſt of new Carthage, we ſhall find to bee within the compaſſe of thirtie miles in breadth, and leſſe ſomewhat in length. And verily, if it were fetched farther off within the maine, the cariage would not quit for the coſt and expences. H I K L M

The

A The Greekes in old time emploied their rishes in drawing of ropes: as may appeare by the very word σχοῖνος, which signifieth with them a rish, and a rope. But afterwards they use their cordage of Date tree leaves, and the thin barks of the Linden or Tillet tree: from whence verily, like and probable it is, That the Carthagians borrowed both their use of Spartum, and manner also of dressing it.

*Sic Spartum nunc restemnunè plantâ è qua restes fiunt, figunt.

Theophrastus writeth, That there is a bulbous plant, with a root like an Onion-head growing about the bankes of rivers; betweene the utmost rind wherof, and that part within, which is good to be eaten, there is a certaine cotton or woollie substance, whereof folke use to make *woollen socks and some such slight peeces of apparell. But he neither named the countrey where they be made, nor setteth downe any other particularities more than this, That the said plant they called Eriophoron [i. Bearing wooll:] so far as ever I could find in any copies comming to my hand. B And albeit *Theophrastus* was otherwise a diligent and curious writer of plants, and searched deep into the nature of simples, foure hundred and ninetie yeares before my time, yet hath hee made no mention at all of Spart, a thing that I have observed and noted in him once alreadie before now. Whereby, evident it is, that the manner of dressing and using Spart, came up after his daies.

*Impilia, nidi a udones.

And since we are entred into a discourse of the wonders of Nature, I will follow on still and continue the same, wherein this may bee one of the greatest, That a thing should live and grow as a plant without root. Looke but to those Mushroomes or Toad-stooles, which are called in Latin Tubera: out of the ground they grow, compassed about on every side with the earth, without root, without any filaments, or so much as small strings & beards resembling a root whereupon C they should rest: the place where they breed doth not swell or beare up one jote, nay, it sheweth no chinke or crevasse at all out of which they should issue: and to conclude, they seeme not once to sticke and cleave to the ground whereupon they stand. A certain barke or pill they seem to have, which encloseth them, such as (to speake plainely) we cannot say is earth indeed, nor any thing else but a very brawnie skin or callositie of the earth. These breed commonly in drie & sandie grounds, in rough places full of shrubs and bushes, and lightly in none else. Oftentimes they exceed the quantitie of good big Quinces, even such as weigh a pound. Two sorts there bee of them. Some be full of sand and grit, and such plague folkes teeth in the eating: others be cleane, and their meat is pure, without any such thing among. They differ also in colour: for there be of them that are red: yee shall have those also that seeme blacke, and yet are white within. But the D best simply are those that come out of Affricke or Barbarie. To determine resolutely whether they grow still from day to day, as other plants; or whether this imperfection of the earth (for better I know not how to call it) commeth at one instant to that full growth that ever it will have; also, whether they live or no; I suppose it is a difficult and hard matter: surely this is certaine, that their putrifaction is much after the manner of wood, and they rot both alike. Many yeares past there are not, since *Lartius Licinius*, sometimes lord Pretour and Governour under the Romans in the province of Spaine, chaunced (of my knowledge) whiles hee was there at Carthage, in biting one of these Mushromes, to meet with a silver Romane denier within it, that turned the edge againe of some of his fore-teeth, and set them awrie. Whereby a man may perceive manifestly, that they bee a certaine excrescence of the very earth, gathering into a round forme, as all other E things else that grow naturally of themselves, and come neither by setting nor sowing.

Chap. III.

*Of the excrescence named *Misy: and of other such like Puffes and Mushromes. Of these flat Fusses and broad Toad-stooles, called *Pezici. Of the plant or hearbe *Laserpitium. Of Magydaris. Of Madder. Of Sope-weed, or the Fullers hearbe Radicula.*

*or, Misoa.
*or, Pezitæ.
*Laser-wort.

WIthin the province of Cyrenaica in Affricke, there is found the like excrescence, called Misy, passing sweet and pleasant, as well in regard of the smell as the taste, more pul- *or, Mison rather, according to *Turneb.* F pous also & fuller of carnositie than the rest: likewise, another of that nature in Thracia, called Ceraunium. As touching all the sorts of Mushromes, Toad-stooles, Puffes, Fusbals or Fusses, these particulars following are observed. First it is known for certaine, That if the Autumn be much disposed to raine, and withall, the aire bee troubled and disquieted with many thunders, during that season: there will be good store of such Mushromes, &c. especially (I say) if it thunder much,

much. Secondly, they will not laſt above one yeare. *Item*, The tendereſt and daintieſt bee thoſe that breed in the Spring, and that indeed is the beſt time for them. *Item*, In ſome countries the overflow of rivers engender Muſhromes, and namely, at Mitylene, where (by report) they will not otherwiſe grow but upon flotengrounds, & namely, in ſuch places whither the water hath brought from Tiara, a certaine vegetative ſeed to breed them. And verily, that Tiara is wonderfully ſtored and repleniſhed with ſuch. As touching the Truffles or Muſhromes of Aſia, the moſt excellent of all others be neare unto Lampſacum and Alopeconneſus: but the beſt that Greece yeeldeth are in the territorie about the citie Elis. In this Toad-ſtoole or Muſhroome kind are thoſe flat Fuſſes and Puffes to be reckoned, which the Greekes name *Pezitæ: as they have no root at all, ſo they bee altogether without either ſtele or taile. G

* or, Pezici.

In the next place to theſe I muſt needs ſpeake of the moſt noble and famous plant Laſerpitium, which the Greekes name Silphium, diſcovered and found firſt in the aboveſaid province of Barbarie Cyrenaica. The juice or liquor drawne out of this hearb they call *Laſer; a drug ſo magnified, of ſuch ſingularitie and uſe in Phyſicke eſpecially, that it was ſold by weight, and a dram thereof coſt ordinarily a *Romane denier. For theſe many yeares of late, there is none of this plant to be found in that countrey of Cyrenaica beforeſaid: for that the Publicans and Farmers of the paſtures & grounds there, (under the people of Rome) do put in their cattell among theſe plants, and eat all downe by that meanes; finding thereby a greater gaine and commoditie, than by letting them ſtand for the juice or liquor aforeſaid. One onely ſtalke or ſtem thereof hath ben found in our daies, which was ſent unto the Emperour *Nero* as a preſent, for a great noveltie. If it chaunce at any time, that either ſheepe or goat (which commonly bite neare to the ground) doe light upon a young plant thereof, newly peeping forth and not evident to bee ſeene, you ſhall know it by theſe ſignes, The ſheepe preſently ſo ſoone as ſhe hath taſted it, will drop aſleepe, and the goat fall a ſneeſing. For theſe many years, the merchants have brought us into Italie no other *Laſer, than that which groweth abundantly in Perſis or Media, and in Armenia: but it is far inferior to this of Cyrenaica, and commeth ſhort of it for goodneſſe. And this that wee have is no better than it ſhould be, for they ſophiſticate and corrupt it with gum, with Sagapeum, or els with bruſed Beanes. In regard of which ſcarſitie, I cannot chuſe but remember that which befell at Rome in that yeare wherein *C. Valerius* and *M. Herennius* were Conſuls, when by great good fortune there was brought from Cyrenæ thirtie pound weight of the beſt Laſer, and ſet abroad to be ſeene in open place, of all commers. As alſo I may not let paſſe another occurrent, namely, how *Cæſar* Dictatour at the beginning of the civile war, tooke forth openly out of the chamber of the citie, with other treaſure both of gold and ſilver, a hundred and eleven pounds of the beſt Laſer. Moreover, this one thing more I cannot forget: the beſt and moſt renowned Greeke Authors have left in writing, That ſeven years before the foundation of the citie Cyrenæ, which was built a hundred fortie and three yeares after our citie of Rome, this plant Laſerpitium that beareth the ſaid Laſer, was engendered at one inſtant, by occaſion of a certaine thicke, groſſe, and blacke ſhewer of raine in manner of pitch, which ſuddainely fell and drenched the ground, about the hortyards or gardens of the Heſperides, and the greater Syrtis: The which raine was effectuall, and left the ſtrength thereof, for the compaſſe of *foure thouſand ſtadia within Affricke or Barbarie. They affirme moreover, That the hearbe Laſerpitium, there growing, is of ſo ſavage and churliſh a nature, that it cannot abide any culture or good ordering by mans hand: but if one ſhould goe about to tend and cheriſh it, it would rather chuſe to be gone into the deſert and unpeopled parts of the counirey, or elſe winder away & die. Moreover, they ſet down this deſcription of it, That it hath many roots, & thoſe big and thicke; a ſtem or ſtalke, reſembling the hearb Sagapeum or Fennel-geant, howbeit, not altogether ſo great: the leaves of this plant, which they termed by the name of Maſpetum come very near in all reſpects to thoſe of Smallach or Perſely. As touching the ſeed that it beareth, flat and thin it is in manner of leaves: but the leafe it ſelfe therof, ſheddeth in the Spring time. The cattel that uſe to feed therupon (and wherof they be very greedie) firſt fall a ſcouring: but afterwards, when they be cleanſed and rid of ill humors, begin to wax fat: and their fleſh by this meanes becommeth wonderfull ſweet and pleaſant. They report moreover, That after the leaves be fallen, men alſo were wont in old time to eat the ſtem or ſtalke thereof, either roſted and baked under the cindres, or elſe boiled and ſodden in water: and their bodies likewiſe for the firſt 40 daies enſuing, did nothing but purge untill they were cleared of all diſeaſes, breeding by occaſion of any Cacochymie or collection of corrupt humors within them. H I K L M

* Some take it for *Benioin*, or *Aſa dulcis*.

Now

A Now concerning the juice or ſoveraigne liquour beforeſaid, the manner was to draw it after two ſorts; to wit, by ſcarification, either out of the root; or forth of the ſtem and maiſter ſtalke. And hereof it came to have two names, Rhizias and Caulias. But the later of theſe twain, to wit, that which came of the ſtem, was counted the worſt, ſubject to putrifaction, and ſold cheaper than the other. To come now to the root of Laſerpitium, it hath a blacke rind or barke upon it, wherewith the merchants uſe to ſophiſticat many of their drugs. As for the manner of dreſſing and ordering the juice thereof: it was no ſooner drawne, but they put it into certaine veſſels, together with brans among; then ever and anone they plied it with ſtirring and ſhogging, untill it had loſt the cruditie and verdure thereof, and by that working came to the maturitie and perfection: for if it were not thus well followed, ſoone would it catch a vinow, begin to putrifie, and ſo
B continue but a while. In this worke of theirs they had an eie unto the colour how it chaunged: for when they perceived it to be high, and that they ſaw it once drie and have done ſweating & breathing out the raw humiditie and vapour within, then they knew thereby that it was wrought ſufficiently, and come to the full ripeneſſe. Others there bee who ſay, that the root of Laſerpitium beareth more than a cubit in bigneſſe, and that out of it there ſwelleth an excreſcence, above the ground, out of which there was wont by way of inciſion to iſſue forth a certaine white juice in manner of milke: upon which grew the ſtalke or ſtem which they called Magydaris. And they affirme beſides, that it beareth leafy flat graines for the ſeed, in colour like gold, which ſhed preſently upon the riſing of the Dog-ſtar, eſpecially if the wind be South. Of which grains or ſeeds fallen to the ground, young plants of Laſerpitium uſe to grow up underneath, which within the
C compaſſe of one yeare will thrive both in root and ſtem to the juſt and full perfection. They have written moreover, that the uſe was to dig about their roots, and to lay them bare at certaine times of the yeare. Alſo, that they ſerved not to purge cattell as is beforeſaid, but to cure them if they were diſeaſed: for upon the eating thereof either they mended preſently, or elſe ended and died out of hand; but few they were that miſcaried in this ſort. As touching the former opinion of purging and ſcouring, true it is, that it agreeth well to the other Silphium or Laſerpitium of Perſia, aforeſaid. Another kind there is of it, named Magydaris, more tender & leſſe forcible & ſtrong in operation than the former; and affourdeth no ſuch juice or liquor at all: it groweth about Syria, and commeth not up in all the region about Cyrenæ.

Moreover, upon the mount Pernaſſus there is great plentie found of a certaine hearb, which
D the inhabitants would needs have to bee Laſerpitium, and ſo they call it: wherewith indeed they are wont to abuſe and ſophiſticat that ſingular and divine plant, the true Laſerpitium, ſo highly commended, and of ſo great account and eſtimation. The principall and beſt triall of the true and ſyncere Laſer, is taken from the colour, ſomewhat enclining to redneſſe without: breake it, you ſhall have it appeare white within: and anone tranſparent. If you drop water upon it, or otherwiſe thin ſpittle, it will reſolve and melt. Much uſe there is of it in many medicines, for to cure mens maladies.

Two plants more there bee, well knowne to the common ſort and baſe multitude, and to ſay a truth, few elſe are acquainted with them, notwithſtanding they be commodities of much gaine, and many a penie is gotten thereby. The firſt is Madder, in great requeſt among diers and curri-
E ers: and for to ſet a colour upon their wooll and leather, right neceſſarie. The beſt of all and moſt commended is our Madder of Italie, principally that which groweth about villages neare unto our citie of Rome. And yet, there is no countrey or province lightly but is full of it. It commeth up of the owne accord, and is ſowed beſides of ſeed, and ſet of ſlips in manner of Ervile. Howbeit, a prickie ſtalke it hath of the owne: the ſame is alſo full of joints and knots, and commonly about every one of them it hath five leaves growing round in a circle. The ſeed is red. What medicinable vertues it hath, and to what purpoſe it ſerveth in Phyſicke, I will declare in place convenient.

The ſecond is that which is called in Latine Radicula, [*i.* Sope-wort:] an hearb, the juice wherof Fullers uſe ſo much to ſcoure their wooll withall; and wonderfull it is to ſee how white, how pure,
F how heat and ſoft it will make it. Beeing ſet, it will come up and grow in any place: but of it ſelfe without mans hand, it groweth moſt in Aſia & Syria, among rough, craggie, & ſtonie grounds. The beſt is that which is found beyond the river Euphrates, and that beareth a ſtem like tall Fenell, howbeit ſmall and ſlender, and whereof the inhabitants of the country there doe make a delicat diſh; for beſides that it hath a commendable taſt and much deſired, it giveth a pleaſant co-

lour

lour to what meat ſoever is ſodden in the pot with it. It beareth a leaſe like the Olive: the Greeks G
call it Strution: it floureth in Summer: lovely it is to the eie, but no ſmell at all it hath to content the noſe: prickie moreover it is like a thorne, and the ſtalke notwithſtanding covered with a ſoft downe: ſeed hath it none; but a big root, which they uſe to cut, ſhred, and mince ſmall for the purpoſes beforeſaid.

Chap. iiii.

The manner of trimming and ordering Gardens: the ſorting of all thoſe things that grow out of the Earth, into their due places, beſides corne and plants bearing fruit.

H

IT remaineth now to treat of Gardens, and the carefull diligence thereto belonging: a commendable thing in it ſelfe, and recommended unto us beſides by our fore-fathers and auncient writers, who had nothing (to ſpeake of) in more account and admiration in old time, than the gardens of the Heſperides, of *Adonis*, and *Alcinoüs*: as alſo thoſe pendant gardens upon tarraces and leads of houſes, whether they were thoſe that *Semyramis* Queene of Babylon, or *Cyrus* K. of Aſſyria, deviſed and cauſed to bee made. Of which, and of their workmanſhip, my intent is to make a diſcourſe in ſome other booke. Now for this preſent (to goe no farther than Rome) the Romane KK. verily themſelves made great ſtore of gardens, & ſet their minds upon them: for ſo we read that *Tarquin* ſurnamed the Prowd (the laſt king of Rome) was in his garden when he gave diſpatch unto that meſſenger that was ſent from his ſonne about a cruell and I
bloudie errand, for to know his fathers advice and pleaſure as touching the citizens of Gabij. In all the twelve tables throughout which containe our auncient lawes of Rome, there is no mention made ſo much as once of a Grange or Ferme-houſe, but evermore a Garden is taken in that ſignification, and under the name of Hortus [*i.* a Garden] is compriſed Hæredium, that is to ſay, an Heritage or Domaine: and hereupon grew by conſequence, a certain religious or ridiculous ſuperſtition rather, of ſome whome wee ſee ceremoniouſly to ſacre and bleſſe their garden and hortyard dores onely, for to preſerve them againſt the witchcraft and ſorcerie of ſpightfull and envious perſons. And therefore they uſe to ſet up in gardens, ridiculous and fooliſh images of Satyres, Antiques, and * ſuch like, as good keepers and remedies againſt envie and witchcraft; howſoever *Plautus* aſſigneth the cuſtodie of gardens to the protection of the goddeſſe *Venus*. K
And even in theſe our daies, under the name of Gardens and Hortyards, there goe many daintie places of pleaſure within the very citie: under the colour alſo and title of them, men are poſſeſſed of faire cloſes and pleaſant fields, yea and of proper houſes with a good circuit of ground lying to them, like pretie fermes and graunges in the countrey: all which, they tearme by the name of Gardens. The invention to have gardens within a citie, came up firſt by *Epicurus* the doctor and maſter of all voluptuous idlenes, who deviſed ſuch gardens of pleaſance in Athens: for before his time, the manner was not in any citie, to dwell (as it were) in the countrey, and ſo to make citie and countrey all one, but all their gardens were in the villages without. Certes at Rome, a good Garden and no more, was thought a poore mans chievance; it went (I ſay) for land and living. The Garden was the poore commoners ſhambles, it was all the market place he L
had for to provide himſelfe of victuals. O what a bleſſed, what a ſecure, and harmeleſſe life was that, ſo long as men could be content to take up with ſuch a pittance, and ſtay themſelves ſo! but better it is I trow, for to ſatisfie the appetite of our wanton gluttons and bellygods, to ſearch into the botome of the deepe ſea: for to get (I ſay) oyſters of all ſorts, to feare no tempeſt nor ſhipwracke: for to meet with daintie foule, to ſend out one way as far as beyond the river Phaſis for thoſe birds, which a man would thinke were ſure enough and ſecured from the fouler, by reaſon of the fearfull tales that go of them, and of the daunger of thoſe that approch neare unto them (and yet why ſay I ſo, conſidering they are the better eſteemed & more pretious, the farther they be fet and dearer bought:) to have purveyours another way in Numidia and Æthiopia, for the rare birds there about the ſepulchres; among thoſe ſepulchres (I ſay) where in ſtead of meeting M
with game, they ſtumble otherwhiles upon their owne graves and never come home againe: and laſtly, to have others to chace the wild and ſavage beaſts of the forreſt, yea and to maintain fight with them, in daunger to be deuoured as a prey, by thoſe which ſoone after muſt ſerve as veniſon for other men to eat. But to come againe to theſe commodities of the Garden, and the cates

which

* as *Priapus*, *Phallí*, and *Ithyphalli*.

A which they affourd: How cheape be they? how readie at hand? how fitted are they not onely to fill the belly and ſatisfie hunger, but alſo to pleaſe the tooth and content the appetite; were it not that wealth and fulneſſe ſtand in the way: the ſame that loath all things els beſide and diſdaine (no marveile) theſe ordinarie viands. Well mought it be born with and ſuffered, that apples and other fruits of the trees, ſuch as are more exquiſite and ſingular than the reſt, in regard of their beautie, bigneſſe, pleaſant ſavour, or ſtraunge and monſtrous manner of growing, even againſt the courſe of Nature; that theſe dainties (I ſay) ſhould be reſerved for our rich and mightie men of the world; that poore men ſhould bee debarred and forbidden once to taſt thereof. In ſome ſort tollerable alſo it is, that great States and wealthie perſonages ſhould be ſerved at their table with old wines, fined and refined, with wines delaied, neatified, and guelded as it were by paſſing
B through an Ipocras bag; that ſuch ſhould drinke no other but that which was wine before they were borne, how aged ſoever they be and far ſtept in yeares. We may abide moreover, that our graund-paunches and ryotous perſons have deviſed for themſelves a delicate kind of meat out of corne and graine (which ſhould ſerve for bread only) and the ſame made of the fineſt and pureſt floure, boulted and ſearſed from the reſt, and none but that: to ſay nothing of the curious worke in paſtrie, the fine cakes, wafers, and marchpaines, artificially carved, engraved, and painted in imagerie, as if theſe wantons could not live forſooth but of ſuch deviſes. That there ſhould be a difference alſo in bread, anſwerable to the diſtinction of States in the cittie, one ſort for noble Senators, another for the worſhipfull knights and Gentlemen, and a third for the meane commoners and multitude. Finally, that in other victuals there ſhould be a deſcent by ſo many de-
C grees, from the higheſt to the loweſt, may carrie ſome apparence of reaſon and be allowed. How then? muſt there be a diſtinction therfore invented in woorts and garden pot-hearbs? Muſt the difference of perſons according to their purſe, appeare alſo in a diſh of * three farthings price and no better? Surely I ſee no ſenſe nor congruitie at all in this. And yet forſooth ſuch hearbs there be that the tribes of Rome (the greater part I meane of the Roman citizens) may not preſume to eat; as if the earth had brought them foorth for rich men only, being no meat ywis for poore people. Why (ſay they in ſcorne and contempt of povertie) here is the ſtem of a woort ſo well growne, here is a cabbage ſo thriven and fed, that a poore mans boord will not hold it. Certes, dame Nature ordained at the firſt, That Sperage ſhould grow wild and commonly in all places of the field, as if ſhe meant thereby, that every man that would might gather them for to
D eat: and now behold, they are cheriſhed carefully in gardens: and from Ravenna, you ſhall have of theſe garden Sperages ſo faire and big, as three of their crops or heads will weigh a good pound, and are ſold after three a Romane As. O the monſtrous bellies that be now adaies! O the exceſſive gluttonie and gourmandize which now raigneth in the world! Is it any marveile that poore aſſes and ſuch dum beaſts may not feed upon * Thiſtles, when the Commons of Rome are reſtrained and forbidden to eat * Thiſtles and dare not once touch them? And yet here is not all: our waters alſo bee diſtinguiſhed and ſet apart for ſome perſons; even the very Ele-
E ments whereof this world conſiſteth are diſtinct, ſevered, and raunged into ſundrie degrees, and all at the pleaſure of monyed men: for ſome you ſhall have to drinke ſnow, others yce: and will you ſee in one word their folly and vanitie? the very miſerie that high mounzaines are puniſhed and plagued with; they make their pleaſure of, and therewith content and delight the throat. Theſe men lay for to be provided of chilling cold againſt the heat of Summer, and ſeeke by all means that they can poſſible, to have ſnow remaine white ſtill and frozen (as it firſt was) out of winter ſeaſon, even in the hoteſt moneths of the yeare, which are moſt oppoſite unto the nature of ſnow. Some there be, who firſt ſeeth their water, and anon let it congeale againe to yce, after it was once ſcalding hot. Wherby we may ſee, how man never contenteth himſelfe in Natures workes, but croſſe he will be alwaies and peeviſh; and look what pleaſeth her, ſhall diſpleaſe him: for who ever would have thought that any one hearb ſhould have growne for the rich, and not as well for the poore? Well, let no man for all this, caſt about and looke toward mount Sacer, or Aventine hill, that the Commoners againe ſhould by way of inſurrection riſe, and in the
F heat of their bloud depart aſide thither, as ſometimes they did in a mutinous fit of theirs, in high diſcontentment with the Nobilitie. For what needs that, ſince they may be ſure that Death ſhortly will bring them together, and make equall, betweene whom now for a while Riches hath put a bar, and made diſtinction of place and degree.

But now it is time to returne againe unto our gardening, from which we were digreſſed. Certaine

* *Etiam tunc aſſe venali.*

* *Cardunus.*
* Artichokes, which are no better than *Cardui altiles*, i. Garden-Thiſtles.

taine it is, that in old time, there was no market place at Rome yeelded greater impoſt unto the State, than the Hearberie; in ſuch requeſt and ſo much called for, were woorts and pothearbes. In regard of which exactions and paiments evermore going out of their purſes, the Commons in the end complained, laid open their greefes, and made their mone to the Senat, of this burden and heavie load; and never gave they over crying to them ſtill with open mouth, for redreſſe, untill they obtained a full releaſe of rent and cuſtome, raiſed before from the tallage and portage of this kind of ware and commoditie. Whereby it was well knowne and found, by long experience, that there was no one thing of greater revenue, and more aſſured gaine; none that ſtood ſo ſafe and certaine; none leſſe ſubject to the will and pleaſure of Fortune and Caſualtie, than Gardinage: as being taken for no leſſe than a yearely fee, that poore men might make account of as ſure as if it were in their purſe. Againe, for the rent thereof paied to the landlord, there was ever good ſecuritie: the ground or ſoile was a ſufficient ſuretie; the profits thereof were alwaies ſeene and expoſed openly to the eie; and lightly no weather whatſoever hindered the crop and gathering thereof. *Cato* highly commendeth the garden Coules or Cabbages, whereby we may know, that in his daies Gardens were in ſome reſpect. Alſo, in times paſt, as Husbandmen in the country were knowne eſpecially, and their wealth valued by their gardens, ſo when there was a garden-plot ſeen lying out of order and not well kept, men judged ſtreightwaies, that the miſtris or dame there dwelling (for commonly this charge lay upon women) was but an ill houſewife and thriftleſſe in hir houſe: for in default of Gardinage, what remedie was there then, but to draw the purſe ſtrings, and goe for every thing either to the Butcherie or the Hearb-market, and ſo to live upon the pennie. Neither were in thoſe daies Coules or Cabbages, ſo well eſteemed as now they bee: for why? they could not away with double meats one upon another, but condemned all diſhes that required ſome addition, as helpe of ſauce, broth, or ſuch like to draw them downe. This was to ſpare coſt, and by this meanes they ſaved oile. For as touching the pickle ſauce * Garum, all thoſe were reproched for gourmandiſe and gluttonie, who could not eat fleſh or fiſh without it. And therfore men tooke greateſt contentment in their gardens and garden hearbs: thoſe were at hand and readie at all times; no great cooquerie was required to dreſſe ſuch diſhes; no need of fire, no expence of wood and fewell. And hereupon it came, that Salads of hearbs were called * Acedaria, ſo little care and trouble went to the proviſion and making of them. Beſides, light they are and eaſie of digeſtion, they breed no heavineſſe in the head, they offend not the braine nor any of the ſenſes; and leaſt of any thing make quarrell to the loafe and ſpend little bread. That quarter of the garden which ſerveth an houſe with poignant hearbs inſtead of ſawce to give a commendable taſt & ſeaſoning to our meat, ſheweth plainly that the maſter and miſtreſſe thereof were not woont to run in the merchants bookes for ſpicerie, but chaunged the Grocer or Apothecaries ſhop, for the garden; for the ſame contentment they had out of it as from thence: alſo that they ſought not either for pepper out of India, or for any kitchin ſpices tranſported from beyond the ſeas out of far countries. And as for the other quarters ſet out with beds of floures and ſweet ſmelling hearbs, what reckoning was made of them in old time may appeare by this, That a man could not heretofore come by a commoners houſe within the cittie, but he ſhould ſee the windowes beautified with greene quiſhins, wrought and tapiſſed with floures of all colours; reſembling daily to their view the gardens indeed which were in out-villages: inſomuch, as being in the very heart of the citie, they might thinke themſelves in the countrey; untill ſuch time as theſe ſlie theeves and night-hookers, the wicked rable (I ſay) and offſcouring of the baſe multitude (not to be reckoned) committed ſuch fellonious outrages, as forced men to naile up covers and caſes before theſe faire lights and beautifull proſpects. Let us give therfore to Gardens their due honor; let us not (I ſay) deprive things of their credit and authoritie, becauſe they are common and nothing coſtly: for I may tell you, ſome of our nobilitie, yea and the beſt of the citie, have not diſdained to take their ſurnames from thence, nay they ſuppoſed themſelves highly credited and honoured therby. Thus we ſee, that in the noble houſe and linage of the *Valerij*, ſome were not abaſhed nor aſhamed to be called *Lactucini*, in regard of the beſt kind of Lectuce that they either had in their gardens, or affected moſt. And here I cannot chuſe but mention by the way, the grace that hath growne to our name, by occaſion of ſome diligence employed and paines taken this way; whereby certain Cherries beare our name and are called *Pliniana*, in teſtimonie of our affection and love to that fruit: which I remember the rather, for that *Virgil* confeſſeth how hard a thing it is, that ſo ſmall matters as theſe bee, ſhould

G H I K L M

* Much like to our Anchoves.

* *ab ἁ & κνάω.*

grow

A grow into the name and reputation of honour any way. And now to the purpose. No man doubteth, but that a garden should lie to a graunge or ferme-house, and joine close unto it: as also, that above all things there should bee water at commaund, from some river or brooke running under, yea, and through it, if it were possible: if not so, yet that they are to be watered with pit water fed with Spring, either drawn up by plain poles, hooks, and buckets; or forced by pumps and such like, going with the strength of wind within enclosed, or els weighed with Swipes & Cranes. Moreover, that a garden-plot should bee broken up and have the first digging presently upon the comming of the West wind Favonius in the beginning of the Spring: and for any thing that must be sown or set there, against Autumne, it ought to be prepared & dressed readie for to receive seeds and sets, foureteene daies after: but for Winter stuffe, it should have a stirring or se-
B cond tilth and delving before the Winter Sunstead or shortest day of the yeare. Also, this is to be noted, that there would not be a greater plot of ground taken in, empaled and fenced about for a garden, than of eight acres or Iugera at the most. Now for the manuring & ordering thereof: first, for three foot deepe the dung would be tempered and mingled with the mould. *Item*, It ought to be divided in principall quarters: the same also must be set out into severall beds, raised somwhat high and lying upward. *Item*, Requisit it is, that every quarter have as well certaine open gutters or furrowes drawne about them, as convenient allies betweene to give both passage for men to come and goe gainely; and also a currant to the course of water that shall bee let in, when the springs be set open or sluces drawne.

Garden plants and hearbes be not all commendable in one and the same respect. For of some
C the goodnesse lieth onely in their bulbous and round root: of others contrariwise in their head aloft. There be of them that have no part good but their stem or maister stalke: and there are for them againe, the leaves whereof be only eaten. Now, a man shall have amongst them those that are wholesome meat, both leafe and stalke. In some the seed or graine, in other the outward pill or rind alone of the root is in request. And as there be that tast well in the skin or cartilage & gristly substance without-foorth, so there are that have either their pulpous carnositie within, or else their fleshie coat above, as daintie. All the goodnesse of many of them lieth hidden within the earth: and of as many againe above the ground: and yet some there bee that are all one, as good within as without. Some traine along and runne by the ground growing on end still as they creepe, as Gourds and Cucumbers. And yet the same, as well as they love to bee neare
D the earth, yet are led upon trailes, and hang thereon, yea, and bee knowne for to rampe upon trees: Howbeit, much weightier and better nourished bee they that keepe beneath. As for the Cucumber, it is the cartilage substance of the fruit thereof, that delighteth and pleaseth our tast: for of all fruits this propertie it alone hath, that the utmost rind which it beareth, groweth to a very wood when it is once ripe. Within the earth lie hidden and are kept all Winter, Raddishes, Navews, Turneps or Rapes, Elecampane also after another sort; so doe Skirworts, and Parseneps or Wypes.

Moreover, this I would advertise the Reader, that when I tearme some hearbes Ferulacea, I meane such as resemble in stalke Dill or the great Mallowes. For some writers doe report, That in Arabia there be a kind of Mallowes, which after they have growne six or seven months, come
E to bee in the nature of pretie trees: insomuch, as their stalkes streightwaies serve in stead of walking staves. But what should I stand upon this? In Mauritania, by report of travellers, neare the frith or arme of the sea adjoining to Lixos, the head cittie of Fez, where sometimes (as folke say) were the hort-yards and gardens of the Hesperides, not above halfe a quarter of a mile from the maine Ocean, hard unto the chappell of *Hercules* (farre more auncient than that temple of his, which is in the Island Calis) there groweth a Mallow, that is a verie tree indeed: in height it is twentie foot, and in bodie bigger and thicker than any man can fadome. In this kind I meane for to raunge the Hempe likewise. And as I purpose to tearme such Ferulacea; so there bee some others, that I will call Carnosa, such as resemble the river or fresh-water Spunges, which commonly are seene upon over-floten meddowes, where the water standeth. For as
F touching the fungous substance or callositie of some plants, I have alreadie spoken thereof in the Treatise of Wood and Trees, and of their nature: Likewise in our late discourse of another sort of Mushroomes and Toad-stooles.

Chap. v.

Of Garden plants, their natures, kinds, and severall histories.

OF the cartilage and pulpous kind (such I meane onely, whereof there is nothing good but that which is above ground) I reckon the Cucumber: a fruit that *Tiberius* the Emperour much loved and affected: for he tooke such a wonderous delight and pleasure therein, that there was not a day went over his head, but he had them served up to his table. The beds and gardens wherein they grew were such as went upon frames to be removed every way with wheels: and as his Gardiners could in Summer time skill how to set them forward unto the Sunne; so again in Winter, during the cold and frostie daies, they could draw them backe into certaine high covert buildings exposed to the Sun, and there house them under rouse. Moreover, I find in some auncient Greeke writers, that their seed ought to lie two daies in steep, or infused in honied milk, before they be prickt or set into the ground: for by that meanes the Cucumbers will be the sweeter and more pleasant. The nature of them is to grow in what forme & fashion soever that a man would have them. Throughout all Italie, greene they be of colour, and least of any others: in the out-provinces they be as faire and great, and those either of a yellow colour, like wax and citrons, or else blacke. In Affrick or Barbarie men take delight to have the greatest plentie of them; whereas in Mœsia they lay for to have them passing big and huge. Now when they exceed in greatnes, they be called Pepones, *i.* Melons or Pompons. Let a man eat them alone, they will lie raw and greene in the stomacke a whole day, and never be digested: howbeit, with meats they are not unholesome: and yet for the most part swim they will aloft, and ride upon a mans stomacke. A wonderfull thing in their nature: they cannot abide oile in any wise, but water they love well; insomuch, as if they be cut off, or fallen from the place where they grew, they wind and creepe therinto, if it bee but a little way off: contrariwise, flie they will as fast from oile, if a man set it by them; and in case any thing bee in their way to let them, or that they hang still upon their plant, a man shall perceive how they will turne up and crooke, to shun and avoid it. This amitie to the one, and enmitie to the other, may be seene even in one nights space: for if a man set under them, foure fingers off where they grow, a vessell with water overnight, he shall see by the morning that they will come down unto it: contrariwise, let oile stand the like distance from them, shrinke they will from it, and hooke upward. Marke another experiment in the Cucumber. If when it hath done flouring, you enter the knot of the fruit into a long lane or trunke, it will grow to a woonderfull length. But behold a very strange and new fashion of them in Campane, for there you shall have abundance of them come up in forme of a Quince. And as I heare say, one of them chaunced so to grow first at a very venture: but afterwards from the seed of it came a whole race and progenie of the like, which thereupon they call Melopepones, as a man would say, the Quince-Pompions or Cucumbers. These never hang on high, but go low by the ground, and gather round in forme of a globe. A strange case it is of this kind: for, over and besides their shape, their colour, and savour different from the rest; they are no sooner ripe, but presently they fall from the stele or taile whereto they grew, notwithstanding they hang not hollow from the ground, where their owne poise might weigh them downe. *Columella* telleth of a pretie devise that hee hath of his owne, how to keepe of them fresh all the yeare long. Chuse (quoth he) the biggest bramble that you can meet withall among a thousand, translate it into a warme sun-shine banke, and there replant it: then cut it off, leaving not above two fingers breadth from the root above the ground [but this must be done about the Spring Æquinox in mid-March:] then take a Cucumber seed, and set it within the soft pith of the said bramble, bank it well round about with fine fresh mould & dung blended together: This is the way, he assureth us, to make that the roots therof bearing such Cucumbers or Melons, will abide the greatest cold in Winter, and never shrink at it. Of Cucumbers, the Greeks have set down three kinds, to wit, the Laconick, the Scytalick and the Bœoticke. Of which, as they say, the first sort only they be that love waters so well. Some there be who prescribe to take the seed either of Cucumber or Melon, & to temper the same in the juice of a certain hearb stamped, which they call *Culix, and then to sow it, perswading us that we shall have fruit thereof without any seed.

Of the like nature (I meane for their manner of growing) be the Gourds. Winter and all cold weather they cannot endure: they love also places well watered & dunged. As wel Gourds, as the Cucumbers or Melons above said, are commonly sowed between the Æquinox in March, & the Sunstead in Iune; provided alwaies, that their seed lie in a trench within the ground, a foot and a halfe

*Some take it for *Coniza*, *i.* Fleabane Mullet.

A halfe deep. But invery deed, the beſt & meeteſt time to ſow them, is about the feaſt Parilia, howſoever there be ſome that would have the ſeed of Gourds to be put into the ground preſently after the Calends or firſt day of March: but of Cucumbers about the Nones, *i.* the ſeventh day therof; or, at fartheſt, by the feaſt or holydaies of *Minerva*, named Quinquatrus. They love both alike for to creepe & crawle with their winding top-branches or tendrels, and gladly they would be clambering upon walls, and climbing up to the houſe-roofe, if they can meet with any rough places to take hold by: for naturally they are given to mount on high. Howbeit, their ſtrength is not anſwerable to their will and deſire: for ſtand they cannot alone without the helpe of ſome props, forkes, or railes, to ſtay them upright. Exceeding forward and ſwift they be in growth. They runne on end when they are ſet on it: and if they may bee borne up and ſuſteined in manner aforeſaid,
B they will gently overſhade galleries, walking places, arbours, frames, and allies under them in a garden, and that right quickly. In regard of which nature and behavior of theirs, two principall kinds there be of them, the one Camerarium, as one would ſay, The Frame or Traile-Gourd, and Cucumber, which climbeth aloft: the other, Plebeium, *i.* the Vulgar and Common, which creepeth along the ground beneath. In the former kind it is worth the noting, to ſee how the fruit (heavie as it is) hangeth ſtiffe poiſed as it were in the wind, and will not ſtir, notwithſtanding the ſtele whereunto it groweth bee wonderous fine and ſmall. Moreover, Gourds alſo may be faſhioned in the head every way as a man will, like as the Cucumbers or Melons beforenamed: and ſpecially within wicker caſes made of pliable oiſiers, into which they are put for to grow and to take their forme, ſo ſoon as they have caſt their bloſſome. The nature of them (I ſay) is to receive
C what figure a man will force and put them to: but commonly ſhaped they are in their growth, like to a ſerpent, winding and turning every way. There have beene knowne of them (ſuch I meane as were of the Traile-kind) being led upon a frame from the ground, were permitted to run at libertie, which grew to an incredible length: for one of them hath beene ſeene nine foot long. As for Cucumbers, they bloume not all at once, but by peece-meale, floure after floure, now one and then another: yea, and floure upon floure, one upon the head of another. Howſoever the Cucumber loveth wateriſh grounds, yet can hee abide drier places alſo. Covered all over this plant and fruit is, with a white downe, even at the firſt: but eſpecially all the while he is in his growth.

Gourds are emploied ſundrie waies, and to many more uſes than Cucumbers. For, firſt their young and tender ſtalkes be very good meat, and being dreſſed, are ſerved up as a diſh to the ta-
D ble: but the rind is of a cleane contrarie nature. Gourds of late time came to bee uſed in ſtouves and baines for pots and pitchers: but long before that they ſtood in ſteed of rundlets or ſmall barrels to keepe wine in. The greene of this kind hath a tender rind, which muſt bee ſcraped notwithſtanding, before a diſh of meat can be made thereof. And certes, albeit Gourds be of digeſtion hard, and ſuch as will not throughly be concocted in a mans ſtomack, yet they are taken to be a light, mild, and wholeſome meat, as they be handled and dreſſed diverſe waies: for that they make not a mans bellie to ſwell, as ſome meats doe. Of thoſe ſeeds which bee found within the gourd next to the necke thereof, if they be ſet, come the long gourds commonly: & ſuch lightly you ſhall have engendred of thoſe alſo that are in the bottome: howbeit, nothing comparable to the other. Thoſe that lie in the middeſt bring forth round ones: but from the ſeeds that are ta-
E ken out of the ſides, ordinarily there grow the ſhorter ſort of gourds, ſuch as be thicke & broad. Theſe graines or ſeeds would be handled in this manner. Firſt they are dried in the ſhaddow: and afterwards when a man liſt to ſow them, they ought to bee ſteeped in water. The longer and ſlenderer that a Gourd is, the better meat it yeeldeth and more pleaſant to be eaten: and therefore it is, that they be thought more wholeſome, which grew hanging upon Treiles; ſuch indeed have leaſt ſtore of ſeed within them. Howbeit, wax they once hard, away with them out of the kitchin, for then they have loſt all their grace and goodneſſe which commended them to the cookes dreſſer. Such as are to be kept for ſeed, the manner is not to cut up before Winter: and then are they to hang or ſtand a drying in the ſmoake, as proper ſtuffe and implements to bee ſeene in a countrie houſe, to keep (as good chaffer) ſeeds for the gardener againſt the time. Moreover, there
F is a meanes deviſed, how to preſerve them and Cucumbers too, for meat, ſound and good almoſt till new come; & that is, by laying both the one and the other in a kind of brine or pickle. Some ſay alſo, that they may be kept freſh and greene, enterred in a cave or ditch under the ground in ſome darke and ſhadie place, with a good courſe or bed of ſand laid under them, and well covered afterwards with drie hey, and earth upon the ſame in the end. Over & beſides, as in all plants

and hearbs in manner of the Garden, there bee both wild and tame: so is there of Gourds and Cucumbers both, a certain * savage kind. Such are not for the kitchin, but for the Apothecaries shop, and good onely in Physicke: and therefore I will put off for this present, the discourse of them and their nature, reserving them for their severall treatises in other books concerning such medicinable simples. G

* Cucumis sylvestris. * Colocynthis, or, Coloquintida.

As touching the rest of Garden-plants, which are of the like cartilage and pulpous substance, they be all the sort of them, roots growing hidden within the ground: among which, I might seeme to have written alreadie fully and sufficiently of Rapes and Turneps, but that the Physicians have observed in them both sexes, to wit, masculine & fœminine: for the rounder kind they will have to be the male; but the broader and flatter sort, which also are somewhat hollow, they account the female: and these last, they hold to be the better far and more pleasant, as being easier to be kept and condite: which also, if they be often remooved and replanted, will turn to be males. Physicians likewise have set downe five kinds of Navews, namely, the Corinthian, the Cleonæan, the Liothasian, the Bœotian, and that which simply by it selfe they called the greene Navew. Of all these, the Corinthian Navews grow to a great bignesse, and in manner all the root is seene naked above ground: for this is the only kind that coveteth to be aloft, and groweth not downward into the earth as the rest doe. As for the Liothasian (some call it also the Thracian) of all others it will abide and endure frost and cold weather best. Next to it, is the Bœotian Navew, sweet in tast, differing from the rest in the notable shortnesse and roundnesse withall that the root carrieth; nothing at all like to the Cleonæan, which is passing long. Generally, this is observed as a rule, That all Navews, the slenderer, smaller, and smoother leaves that they beare, the more pleasant is their root to the tast: and contrariwise, the rougher that they be, the more cornered also and prickie, the bitterer they are. There is a wild kind of them besides, the leaves whereof resemble Rocket. The best Navews that are sold at Rome, be those that come from Amiternum in Bruzze. The next to them in goodnesse, are those of Nursium. In the third place are they to be raunged, which our countrey * about Verona yeeldeth. As concerning all things els, and namely the manner of sowing them, I have said enough in the treatise of Rapes or Turneps. H I

* Or rather Italie.

As for Radishes, their roots do consist of a rind without, and a cartilage or pulpous substance within: and verely many of them are knowne to have a thicker skin or rind than the barke is of some trees: bitter such are, more or lesse, according to the thicknesse of the said rind: otherwhiles also, the rest is all pith, and as hard as wood. All Radishes breed wind wonderfull much, and provoke a man that eateth them, to belch. A base and homely meat therefore it is, and not for a gentlemans table, especially if it bee eaten with other woorts, as Beets: mary if a man take them with unripe olives condite, he shall neither belch or rift wind so much, ne yet so sower and stinking will his breath be afterwards. The Ægyptians make marveilous great account of Radishes, for the plentie of oyle that they draw out of the seed: and therefore a great desire they have to sow them if they may: for as they find it more gainfull than corn, so they pay lesse tribute and custome, in regard of that commoditie; and yet there is nothing yeeldeth more abundance of oile. * The Greekes have made three sorts of Radishes, differing all in leafe. The first, crisped and curled like a ruffe; the second, smooth and plaine; the third, wild and savadge: and these wild ones verily have smooth leaves, but short and round: plentifull also they be, and otherwise full of branches: a rough and harsh tast they have; howbeit medicinable they be, and as good as a purgation to loosen the belly & make it laxative. As for the other two former kinds, a difference there is in the seed: for in some, it is very faire and good; in others, as small and bad: howbeit these imperfections light upon none but such as have the crisped and frizled leaves. * Our countreymen here in Italy have made other kinds thereof; to wit, Algiclense, so called of the place: long they be, transparent and cleare, that a man may see through them. A second sort there be fashioned in manner of Rape roots, and those they call Syriaca, the sweetest for the most part of all others, and renderest; such also as will hold out best against frost & winter weather. Yet the principall and very best in deed are those, which as it should seeme were but lately brought out of Syria (at leastwise the seed of them) for that in no writers there is found any mention made of them: and they will continue all winter long. Over and besides all these, there is one savage kind of them more, which the Greekes name Agrion: the inhabitants of Pontus, Armon; others Leuce; and our countreymen give it the name of Armoracia: more shew it maketh in leafe than in the root or all the bodie besides. Moreover, the best token to know good Radishes by, is their K L M

* Theophrastus writeth all this of Brassica, i. Colewoort. See how Pliny is overseene: but that is no newes with him.

* Here hee seemeth to come againe to the Radish indeed.

stem

A ſtem or ſtalke: for ſuch as bite at the tongues end, have rounder and longer ſtems than the other that be mild: they have long and hollow gutters alſo: the leaves beſides, are more bitter and unſavorie, cornered, more rough, and untoward to be handled. Radiſh ſeed would willingly be ſowne in a looſe or light ground, and natheleſſe moiſt enough: it cannot abide ranke mucke, but contenteth it ſelfe with rotten chaffe or pugs, and ſuch like plaine mullock. It liketh and thriveth ſo well in cold countries, that in Germanie a man ſhall have their roots as big as prettie babes. To have Radiſh roots in the ſpring, the ſeed would be ſowed preſently after the Ides or 13 day of Februarie: and a ſecond time againe about the feaſt of * *Vulcan*, which is in deed the better ſeaſon for Seednes. Mary there be that put the ſeeds into the ground in March, Aprill, & September. When they are come up and begin to grow to ſome bigneſſe, it is very good to interre
B and cover with mould round about the leaves, now one, and then another; but in any caſe to banke the roots well with earth: for looke how much appeareth bare above ground, prooves either to be hard, or els fungous and hollow like a Kex, and nothing good to be eaten. *Ariſtomachus* would have them to be ſtript from their leaves in winter, and in any hand to be banked well about, that the water ſtand not there in any hollow furrow or hole lower than the other ground; promiſing us by this meanes, that they will proove faire and big againſt Summer. Some have reported, that if a man make a hole in the ground with as big a ſtake as hee will, and ſtrew or lay it in the bottom with a bed of chaffe ſix fingers deepe, and on it beſtow his ſeed, with muck and mould heaped thereupon, the roots will grow ſo big as to fill up the ſaid hole full. Howbeit, in briefe, Radiſhes are beſt nouriſhed and maintained in ſalt grounds: and therefore with ſuch kind
C of brackiſh waters they uſe to be watered: which is the reaſon, that in Ægypt ther are the ſweeteſt and daintieſt Radiſhes in the world, for that they are bedewed and ſprinkled with Nitre. And verily it is thought, that they will looſe all their bitterneſſe whatſoever, if they be corned or ſeaſoned with ſalt, yea and become as if they were ſodden and condite: for be they boiled once, they prove ſweet and ſerve to be eaten in ſtead of Navews. And yet Phyſicians give counſell and preſcribe, That they ſhould be eaten raw in a morning with ſalt, when a man is faſting, for to gather into the ſtomacke the ſharpe humors and excrements which charge the belly and entrails: and thus taken, they are of opinion, That it is a good preparative to vomit, and to open the paſſages well for to void thoſe ſuperfluities. They give out alſo, That the juice of Radiſh roots is ſingular good and neceſſarie for the midriffe, and the precordiall parts about the heart; and namely, that no-
D thing els but it, was able to cure a Phthiſicke or ulcer of the lungs, which had ſetled deepe and taken to the heart: The experiment and proofe whereof was found and ſeen in Ægypt, by occaſion that the KK. there, cauſed dead bodies to be cut up, and anatomies to be made, for to ſearch out the maladies whereof men died. It is reported, that the Greekes (as they be otherwiſe vaine in all their actions) ſo highly preferred the Radiſhes before other meats, in regard of their good nouriſhment, that whereas in an oblation out of the Garden-fruits to be offered unto *Apollo* in his temple at Delphos, they dedicated the Beet in ſilver, and the Rape or Turnep in lead, they preſented a Radiſh in beaten gold. A man may know hereby, that *Manius Curius* the great Generall of the Romane armie, was not that countreyman borne; whome the Samnite Embaſſadours (when they brought unto him a great preſent of gold [upon condition to ſurceaſe armes]
E which he meant to refuſe and not accept at their hands) found roſting of a Rape or Turnep root at the chimney fire; according as we find in the Annals and Chronicles of the Roman hiſtorie. To come againe to our Radiſhes, *Moſchion* the Greeke writer ſo highly eſteemed this root, that he compiled one whole booke of the Radiſh, and nothing els. Indeed Radiſhes are thought excellent good with meats in winter time: howbeit they alwaies weare and marre their teeth who eat of them: and yet I aſſure you they will poliſh Ivorie, which is nothing els but the Elephants tooth. * Betweene a Vine and Radiſh, there is by nature a ſecret enmitie and exceeding great hatred, inſomuch as if Radiſhes be ſowed neare unto her, ſhe will wryth and turne away ſenſibly from them.

Touching other ſorts of cartilage or pulpous plants in the garden, wherof I have before ſpo-
F ken, they be all given to run much to pith, and to be of a more woodie ſubſtance. A man would marveile therefore that they ſhould all taſt ſo ſtrong and ſharpe as they doe. Of which there is one kind of wild Parſnep growing of it ſelfe, which in Greeke is * called Staphylinas. A ſecond ſort is ſet of a plant with the root and ſowed of ſeed, either in the prime of Spring, or els in Autumne: howſoever *Hyginus* would have them to bee put into the ground in Februarie, Auguſt,

* 11 Cal. Iun. or as ſome thinke, 13 Cal. Iun. *i.* the 20 or 22. day of May. This feaſt was named alſo *Lufiria*.

* Here *Plinie* forgetteth himſelf again: for this is verified of the Colewort, and not of the Radiſh.

* Some call theſe Madnips.

September, and October; and that the plot where they are to grow, ſhould bee digged and delved very deepe. This root beginneth to bee good at the firſt yeeres end, but better it is if it be two yeers old: howbeit both the one & the other, is counted holſomer in Autumne than at any other ſeaſon of the yeare, eſpecially boiled and ſerved up betweene two platters: and yet dreſſe them ſo as well as you can, they will not be rid of that ſtrong, ranke, and churliſh ſmacke which it hath. As for *Hibiſcum, it differeth from the Parſnip aforeſaid onely in this, That it is more ſlender and ſmaller: rejected altogither from the table, and condemned for no good meat; howbeit medicinable, and uſed much by the Phyſician. A fourth kind there is beſides, reſembling alſo the Parſnip, which our countreymen the Latins name the French Parſnip, but the Greekes Daucus, [*i.* the yellow Douke or Carot] which they have ſubdivided into foure ſpeciall ſorts. The * Skirwirt root or white Parſnip, (which indeed would bee written among other Phyſicke plants) was likewiſe in great name and credit by the meane of the foreſaid Emperour *Tyberius*, who was very earneſt to have them yearely brought out of Germanie, and ever he would call for them at his own table. And indeed about Gelduba (a caſtle ſituate upon the river Rhene in Germanie) there was an excellent kind of them that grew to be paſſing faire, from whence hee was ſerved: whereby it appeareth, that this plant loveth cold regions well. Theſe roots have a ſtring in manner of a pith or ſinew, running all the length thereof, which the cooke uſeth to take forth after they bee ſodden; yet for all that there remaineth ſtill in them a great deale of bitterneſſe: howbeit being well tempered and delaied with a ſauce of mead or honyed wine, and ſo eaten with it, even the ſame bitterneſſe turneth to a good and pleaſant taſt. The greater Parſnip Paſtinaca, hath the like nerve or ſtring aforeſaid (ſuch only I meane as are a yeare old.) The right ſeaſon to ſow the Skirwirt or Parſnip Siſer, is in theſe moneths, to wit, Februarie, March, Aprill, Auguſt, September, and October.

* Some take it for *Althæa*, or the mariſh Mallow.

* *Siſer.*

The *Elecampane hath a root ſhorter than the Skirwirts or Parſnips aforeſaid, but more muſculous and fuller as it were of brawne; bitterer alſo: in which regards, if it be taken ſimply alone, it is adverſe and contrarie to the ſtomacke; but joyned and confected with ſome ſweet things among, it is very holeſome. And many deviſes have ben practiſed with it to take away that harſh and untoward bitterneſſe which it hath, whereby it is become toothſome and pleaſant enough: for ſome there be, who ſtampe it drie and ſo reduce it into a pouder: then they mix it with ſome ſweet liquid ſyrrup, and being thus tempered, ſerve it up. Others ſeeth it in water and vinegre mingled togither, and ſo keep it condite. Infuſed alſo it is many waies, and then afterwards either preſerved in cuit, or incorporat with honey in manner of a conſerve, or els with dried Raiſons of the Sun, or laſt of all with faire and fat Dates. Moreover, divers there be, who after another ſort make a confection thereof; namely with Quinces, with Sorviſes, or Plums, mixing therwith one while Pepper, another while Thyme. And I aſſure you this root thus confected (as is beforeſaid) is ſingular good for faintings; and eſpecially quickneth the dulneſſe and defect of the ſtomacke. The Empreſſe *Iulia Auguſta* paſſed not a day without eating the Elecampane root thus confected and condite: and thereupon came it to be in ſo great name and bruit as it is. The ſeed therof is needleſſe and good for nothing: therefore to maintaine and encreaſe this plant, gardeners uſe commonly to ſet the joynts cut from the root, after the order as they doe Reeds and Canes. The manner is to plant them as well as Parſnips, Skirwirts, and Carots, at both times of Seednes, to wit, the Spring and the Fall: but there would be a good diſtance betweene every ſeed or plant, at leaſt three foot, becauſe they ſpread and braunch very much, and therewith take up a deale of ground. As for the Skirwirt or Parſnip Siſer, it will doe the better if it be remooved and replanted.

* *Inula.*

* *Cariotis*, ſome read *Caricis*, *i.* Figs.

It remaineth now to ſpeake in the next place of plants, with bulbous or onion roots and their nature, which *Cato* recommendeth to Gardeners, and hee would have them to be ſet and ſowed above all others: among which, he moſt eſteemeth them of Megara. Howbeit, of all this bulbous kind, the Sea-onyon Squilla is reputed chiefe and principall, notwithſtanding there is no uſe of it but in Phyſicke, and for to quicken vinegre. As there is none that groweth with a bigger head at the root, ſo there is not any more ægre and biting than it. Of theſe Sea-onyons, there be two kinds medicinable; the male, with the white leafe; the female, with the blacke. There is a third ſort alſo of Squillæ, which is good for to be eaten: the leaves whereof be narrower, and not ſo rough and ſharp as the other, and this they call Epimenidium. All the ſort of theſe Squilles are plentifull in ſeed: howbeit they come up ſooner if they be ſet of cloves or bulbes which

grow

A grow about their ſides. And if a man would have the head of the root wax big, the leaves which uſually be broad and large, ought to be bended downe into the earth round about, and ſo covered with mould; for by this means all the ſap and nouriſhment is diverted from the leafe and runneth backe into the root. Theſe Squilles or Sea-onions grow in exceeding great abundance within the Baleare Iſlands and Ebuſus, as alſo throughout all Spaine. *Pythagoras* the Philoſopher wrote one entire volume of theſe Onions, wherein hee collected their medicinable vertues and properties, which I meane to deliver in the next booke.

As touching other bulbous plants, there bee ſundrie kinds of them, differing all in colour, quantitie, and ſweetneſſe of taſt: for ſome there bee of them good to bee eaten raw, as thoſe of Cherrhoneſus Taurica. Next unto them, are they of Barbarie, and moſt commended for goodB neſſe; & then thoſe that grow in Apulia. The Greeks have ſet downe their diſtinct kinds in theſe tearms, Bulbine, Setanios, Pythios, Acrocorios, * Ægilops, and Siſyrinchios. But ſtraunge it is of this Siſyrinchios laſt named, how the foot and bottom of the root will grow downe ſtill in winter; but in the Spring when the Violets appeare, the ſame diminiſheth and gathereth ſhort upward: by which meanes the head indeed of the root feedeth and thriveth the better. In this ranke of bulbous plants, is to be ſet that, which in Ægypt they call Aron, [*i.* Wake-Robin:] for bigneſſe of the head it commeth next to Squilla beforeſaid: the leaves reſemble the hearb Patience or garden Docke: it riſeth up with a ſtreight ſtem or ſtalke two cubits high, as thicke as a good round cudgell. As touching the root, it is of a ſoft and tender ſubſtance, and may be eaten raw. If you would have good of theſe bulbous roots, you had need to dig them out of the ground C before the Spring; for if you paſſe that time, they will preſently bee the worſe. You ſhall know when they be ripe and in their perfection, by the leaves; for they will begin to wither at the bottom. If they be elder, or if their roots grow ſmall and long, they are rejected as nothing worth. Contrariwiſe, the ruddie root, the rounder, and the biggeſt withall, are moſt commended. Know this moreover, That the bitterneſſe of the root in moſt of them, lyeth in the crowne (as it were) or top of the head; for the middle parts be ſweet. The auncient writers held opinion, That none of theſe bulbous plants would grow, but of ſeed onely: howbeit both in the paſtures and fields about Preneſte, they come up of themſelves: and alſo among the corne lands & arable grounds of the Rhenians, they grow beyond all meaſure.

* rather, *Hemerocalles.*

D

Chap. VI.

Of the roots, leaves, floures, and colours of Garden-hearbs.

All Garden plants ordinarily, put out but one ſingle root apeece; as for example, the Radiſh, Beet, Parſley, and Mallow: howbeit the greateſt and largeſt of all others is the root of the hearb Patience or garden Docke, which is knowne to run downe into the ground three cubits deepe. In the wild of this kind (which is the common Docke) the roots be ſmaller, yet plumpe and ſwelled; whereby, after they be digged up and laid above ground, they will live a long time. Some there be of them, that have hairie ſtrings or beards hanging to their roots, as namely Parſley or Ach, and Mallowes. Others there be againe, which have braunching roots, E as the Baſill. As the roots of ſome bee carnous and fleſhie altogither, and namely of the Beet, but eſpecially of Saffron; ſo in others they conſiſt of rind and carnoſitie both, as we may ſee in Radiſhes and Rapes or Turneps. And ye ſhall have of them that be knottie and full of joynts, as for example, the root of the Quoich graſſe or Dent-de-chien. Such hearbs as have no ſtreight and direct root, run immediatly into hairie threads, as we may ſee plainly in the Orach & Bleet. As for the ſea Onion Squilla, and ſuch bulbous plants, the garden Onions alſo and Garlicke, they put forth their roots ſtreight, and never otherwiſe. Many hearbs there be, which ſpring of their owne accord without ſetting or ſowing, and of ſuch many there be that braunch more and clove in root than in leafe, like as wee may ſee in Aſpalax, *Parietarie of the wall, and Saffron. * *Perdicium.*
Moreover, a man ſhall ſee theſe hearbs floure at once togither with the Aſh, namely, the running F or creeping Thyme, Southernwood, Naphews, Radiſhes, Mints, and Rue; and by that time as others begin to blow, they are readie to ſhed their floures: whereas Baſill putteth forth flours by parcels one after another, beginning firſt beneath and ſo going upward by leiſure: which is the cauſe that of all others it is longeſt in the floure. The ſame is to be ſeene in the hearb Heliotropium, [*i.* Ruds or Turnſol.] In ſome the floures be white, in others yellow, and in others purple.

As

As touching the leaves of hearbs, some are apt to fall from their heads or tops, as in Origan and Elecampane, yea, and otherwhiles in Rue, if some injurie bee done unto it. Of all other hearbs, the blades of Onions and *Chibbols be most hollow. Where by the way I cannot overpasse the foolish superstition of the Ægyptians who use to sweare by Garlicke and Onions, calling them to witnesse in taking their othes, as if they were no lesse than some gods. Of Onions, the Greekes have devised sundrie kinds, to wit, the Sardian, Samothracian, Alsiden, Setanian, Schista, [*i.* the cloven Onion] and Ascalonia [*i.* the little Onions or Scalions] taking that name of Ascalon, a citie in Iurie. They have all of them this propertie besides, to make a mans eies water, and to fetch out teares, if one smell to them, especially they of Cypros: but the Gnidian Onions least of all others, cause one to weepe. In all kinds of them the bodie of the root consisteth of a certain fattie pulpe or cartilage. For quantitie the Setanian be least, except the Tusculane: howbeit, such are sweet. The cloven Onions and the Scalions aforesaid, are proper for to make sauce of. As touching that kind of them called Schista, Gardiners leave them all winter in the ground with their leaves or head standing: in the Spring they pluck off the said leaves, and then shall you see spring forth others underneath, according to the same clifts and divisions, whereupon they tooke the name Schista. After which example, the like practise in all other kinds is prescribed, namely, to pull their leaves off, that they should grow rather big in root, than run up to seed. The Ascalonian Onions have a proper nature and qualitie by themselves: for they bee barren (as it were) from the root, and therefore the Greeks would have them to be sowed of seed, and not otherwise to bee set of heads. Besides, that they should bee transplated and replanted againe late, about the Spring, at what time as they put forth blade: for by this usage (say they) you shall have them burnish and grow thicke, yea, and then make haste, for amends of the former time foreslipt. These must be gathered betimes: for after they be once ripe, quickly will they rot in the ground, if you make not the better haste to plucke them up. If you set or plant their heads, a stalke they will put forth and feed upon it, but the Onion it selfe will consume and come to nothing. Moreover, there is a difference observed in the colour of Onions: for they that grow in Samos and Sardis, bee most white. Those also of Candie be much esteemed: & some there be, who make doubt whether they bee the same that the Ascalonian, or no? for that if they bee sowed of seed, their heads or roots will grow big: set them, they will be all stem and seed, and no head at all. As for the rellish or taste that Onions have, there is no great diversitie, but that some are sweeter than other. Our Onions here in Italie bee all of two sorts principally: the one which serve for sauce to season our meats, which the Greekes call Gethyon Chibbols; but our countreymen the Latines, Pallacana; these are sowne commonly in March, Aprill, and May: the other is the great headed Onion; and these be put into the ground, either after the Æquinox in Autumne, or else after mid Februarie, when the West wind Favonius is aloft. Moreover, Onions are devided into sundrie sorts, according to the degrees of their pleasant or unpleasant and harsh taste; to wit, the Affricane, French Tusculane, and Amiternium. But evermore the best are the roundest. *Item*, The red Onion is more keene and angrie than the white: the drie, and that which hath lien, is more eager & sharp than the greene, newly drawne: the raw also more than the sodden: and finally, the drie by it selfe more than that which is condite and preserved in some liquor for sauce. The Amiternium Onion is planted in cold and moist grounds: and this alone would bee set of a head in manner of Garlick cloves, whereas the rest will come of seed. Onions, the next Summer following after they be sowne, put forth no seed but head only, which groweth, and the leafe or stem drieth and dieth. But the next yeare after by way of interchange, it bringeth forth seed, and then the head rotteth. And therfore every yeare they use to sow Onion-seed apart in one bed by it selfe, for to have Onions: & set Onions for seed in other, by themselves. The best way to keep Onions, is in corn, chaffe, and such like pugs. As for the Chibboll, it hath in manner no distinct head at all, but only a long necke, and therefore it runs in manner all to a greene blade: the order is to cut and sheare it often in manner of porret or leekes; which is the cause that they sow it also of seed, and do not set it. Over and besides, before we sow Onion seed, the plot, by mens saying, ought to have three diggings; for to kill and rid out of the ground the roots of hurtfull weeds: and ten pound of seed ordinarily will sow an acre. Here and there among, there would be Savorey sowne, for the better will the Onions like and prosper with the companie of that hearbe. Also, after the ground is sowne, it requireth weeding, sarcling or raking foure times at least, if not oftener. Our neighbours in Italie sow the Ascalonian Onion in the month of Februarie: whose manner is also to gather Onion

seed

*Gethyum.

G H I K L M

A ſeed when it beginneth once to waxe blacke, before it fall to wither.

Seeing now that I am entred thus far into a diſcourſe of Onions, I ſhall not do amiſſe to treat of Leekes alſo, in regard of the neare affinitie betweene them: and the rather, for that it is not long ſince, that the Porret kind which is often kept downe with clipping and cutting, came into great name and credite, by occaſion of the Emperour *Nero*; who uſed for certaine daies in every moneth for to ſcoure his throat, and cleare his voice, and to take it with oile; on which daies hee did eat nothing elſe, not ſo much as bread. Wee uſe to ſow them of ſeed, after the Æquinox in September: and if we meane to make cut Leekes thereof, the ſeed would be ſowed the thicker. Theſe Leekes are kept downe with clipping and ſhearing ſtill untill the root faile, without removing them out of the ſame bed where they were ſown: and alwaies they muſt be plied with dung.

B But before they be cut, nouriſhed they ought to be, untill they have gotten a good head. When they are well grown, they are to be tranſlated into another bed or quarter, & there replanted: having their uppermoſt leaves lightly ſhrigged off, without comming to the heart or marow, which is their bodie next to the roots: and their heads ſet deeper downeward: yea, and their utmoſt pellicles and skins ſlived from them. In old time they uſed to put under their root a broad flint ſtone, or elſe a tile, which did dilate their heads within the ground, and make them ſpread the better. This they practiſed alſo in other bulbous plants, as Onions, &c. thereby to have the fairer heads. But now in theſe daies the maner is, lightly to barbe & pluck off with a ſarcling hooke, the beards or ſtrings of the root; that being thus nipped and lipped (as it were) they might nouriſh the bodie of the plant, and not diſtract and ſucke away the humor, which is the nutriment of the whole.

C This is notable and wonderfull in the Porret, that joying and liking as it dooth in mucke and fat ground, yet it cannot abide waterie places. Howbeit, in theſe we muſt be ruled by the propertie of the ground, which is all in all. The principall Leekes be in Ægypt: the next are thoſe of Ortia and Aricia. Of the cut Porret or unſet Leekes be two kinds. The one runneth mightily into a greene blade, and the leafe thereof hath very conſpicuous and evident cuts; and this is that the Apothecaries uſe ſo much: the other hath a more pleaſant and yellowiſh leafe, and the ſame rounder, the gaſhes or cuts whereof are ſmaller, and not ſo apparent to the eie. The voice goeth, and generally it is reported, That *Mela* a knight or gentleman of Rome by his place, and Procuratour under *Tiberius* the Emperour, being for ſome miſgovernement in that office, brought into queſtion and accuſed, and thereupon ſent for peremptorily to make his perſonall apparance, deſpai-

D ring utterly of life, tooke the weight of three Romane ſilver deniers in the juice of Leekes, and dranke it off: whereupon hee died incontinently without any paine or torment at all. It is commonly ſaid, That if a man take a greater doſe or receit thereof, it will doe no harme, nor any danger will enſue thereupon.

As touching Garlicke, it is held for certain, That it is a ſoveraigne medicine for many greefs and maladies; eſpecially ſuch as are incident to the countrey peaſants and ruſticall people, who hold it to be as good as a Treacle. The Garlicke head is covered and clad all over with certain very fine and thin pellicles or membranes, which may be parted and divided one from another; under which you ſhall ſee it compact and joined (as it were) together of many cloves in manner of kernils, and thoſe alſo encloſed each one apart within their ſeverall skins. Of a ſharpe and biting

E taſt it is. The more keene and eager alſo you ſhall find it, as it hath more of thoſe cloves aforeſaid in one head. The aire that commeth from it, is as offenſive as that of the Onion, and maketh their breath as ſtrong who eat it: howbeit, ſodden if it bee, it is every way harmeleſſe. The difference and diverſitie of Garlicke ariſeth firſt, from the circumſtance of the time; whereby you ſhall ſee a kind of haſtie-Garlicke, that in threeſcore daies will bee ripe and come to perfection: then, in quantitie: for ſome grow bigger in the head than other. And of this ſort is that which wee call in Latin Vlpicum: and the Greeks, ſome, the Cyprian Garlick; others, *Aphroſcorodon: ſo much commended in Affricke, that it is held for the moſt principall diſh of meat that a Husbandman of the countrey can eat: and bigger it is than our common Garlicke. Being bruſed and braied in a morter together with oile and vineger, it is wonderfull to ſee what a fome and froth will ariſe

F thereof, and to what an height it will ſwell thereby. Some Gardeners there are, who forbid to ſet either this Vlpicum, or the common Garlicke in any even, flat, and levell bed; but to put them in little hillockes [in manner of hop hils] raiſed in forme of caſtles or turrets, three foot diſtant one from another. Now, whereſoever theſe cloves bee ſet in hill or plaine, they ought to lie foure fingers breadth aſunder. And this would not bee forgotten, That ſo ſoone as they ſhew three leaves once,

*or, *Antiſcorodon.*

once, they would be ſarcled, and the mould raiſed from about them: for the oftener they be thus ſerved and laid bare, the fairer heads they will bring. When they begin to grow big and come to their full maturitie, the ſtalkes that they run up unto, muſt be troden downe and moulded over: and this is to prevent, that they ſhould not be over-ranke in blade. In cold countries it is thought better and more profitable to ſet them during the Spring, than at the fall of the leafe. Moreover, if you would have Garlicke, Onions, and ſuch like, not to ſmell ſtrong and ſtinke ſo as they do, the common opinion and rule is, that they ſhould not be ſet or ſowne, but when the Moone is under the earth, nor yet be gathered and taken up but in her conjunction with the Sunne, which is the chaunge. But *Menander*, a Greeke writer, ſaith, That there needs none of all theſe ceremonies for the matter: for if a man would not have his breath ſtinke with eating of Garlicke, let him do no more (quoth hee) but take a Beet root roſted in the embers, and eat it after, it ſhall extinguiſh that hote and ſtrong ſavour, and cauſe the breath to continue ſweet. There bee who thinke, that the fitteſt time of ſetting both the common Garlicke, and alſo the greater kind named Vlpicum, is betweene the two ſet and ordinarie feaſts *Compitalia and *Saturnalia. As for the vulgar Garlicke, it commeth up alſo of ſeed, but ſlowly, and late it will be firſt ere it attaine to the full proofe: for the firſt yeare it getteth a head no thicker than Leekes; the next yeare after, it beginneth to divide into cloves; and in the third it is conſummate and growne to perfection: and ſuch unſet Garlick, ſome are of opinion, to be fairer and better than the reſt. Howbeit, Garlick indeed ſhould not be ſuffered to boll and run up to ſeed, and therefore the blade thereof ought to be wreathed, that it may gather more and ſtronger in the head, and that the cloves afterwards might bee ſet in ſteed of ſeed, for increaſe. Now if a man have a deſire that both Garlicke and Onions may be kept long for his proviſion, their heads muſt be dipped and well plunged in ſalt water, warme: by this meanes indeed laſt they will longer without ſpurting, and be better for any uſe we ſhall put them to, ſave onely to be ſet and replanted into the ground; for barren will they be, and never proſper. And yet divers there are, who thinke it ſufficient at the firſt to hang them in the ſmoke over quick and burning coales: as being perſuaded, that this will ſerve well ynough to keepe them from growing: for certaine it is, that both Garlick and Onions will put forth blade above ground, and when they have ſo done, come to nought themſelves, as having ſpent all their ſubſtance and vertue. Some are of this mind, that the beſt preſerving of Garlicke as well as of Onions, is within chaffe.

*11 *Calend. Januar.*
*14 *Calend. Januar. i.* Betweene the 18 and 21 of December.

There is a kind of Garlicke growing wild in the fields of the owne accord, which they call in Latine Alum [*i.* Crow Garlicke,] which beeing boiled that it ſhould not grow, they commonly throw forth in corne fields for the ſhrewd and unhappie Foules which lie upon the lands, and eat up the ſeed new ſowne: for preſently as any of thoſe birds taſt thereof, they will be ſo drunken and aſtonied therewith, that a man may eaſily take them with his hand: yea, and if one ſtay a little, he ſhall ſee them fall aſleepe therewith. Finally, there is another kind of ſavage or wild Garlicke called Vrſinum, [*i.* Beere Garlick] the head wherof is very ſmall, the blade or leaves great and large, and the ſavor or ſent mild and gentle, in compariſon of the reſt.

Or rather *Anguinum.*

Chap. vii.

In how many daies every hearbe that is ſowed will come up and appeare above ground. The nature of ſeeds. The manner of ſowing any of them. Which they be, whereof there is but one ſingle kind: and which have many ſorts.

AMong all the hearbs ſowne in a garden, theſe come up ſooneſt, to wit, Baſill, Beets, Navews or Turneps, and Rocket: for by the third day the ſeed will breake and ſpurt. Dill ſeed will chit within foure daies, Lectuce in five, Radiſh in ſixe, Cucumbers and Gourds in a ſevennight, but the Cucumber firſt. Creſſes and Muſtard ſeed in five daies, Beets in ſix by Summer time, & by Winter in ten. Orach in eight daies, Onions in nineteen or twentie at the fartheſt, Chibols in ten or twelve at the moſt. Coriander ſeed is more ſtubborne, and will not ſhew ſo ſoone. Saverie and Origan ſeed lieth thirtie daies ere it come: but of all others Parſeley ſeed is lateſt ere it ſpring; for when it commeth up ſooneſt, it is fortie daies firſt: but for the moſt part it lieth fiftie daies before it appeare. Some thing there is alſo in the age of the ſeed: for the newer that the ſeed is either of Leeks, or Chibols, Cucumbers and Gourds, the more haſt it maketh to be above ground: contrariwiſe, Perſely, Beets, garden Creſſes, Saverie, Origan, and Coriander, grow ſooner

A ner of old ſeed. But the Beet ſeed hath a ſtrange and wonderfull qualitie above the reſt: for it will not come up all in one and the ſame yeare. But ſome in the firſt, others in the ſecond, and the reſt in the third. And therfore ſow as much ſeed as you will, yet ſhall you have it grow but indifferently. There be hearbes which will grow and beare but one yeare and no more: and there bee other againe which will continue many yeares together, as for example, Perſely, Porret, and Chibbols. For, ſow theſe but once in a garden, they will beare from yeare to yeare from the ſame root, or els ſow themſelves. The moſt part of hearbes do beare round ſeed, in ſome the ſeeds are long; in few, broad and flat in manner of a leafe, as in Orach. You ſhall have ſeed alſo narrow and chamfeted, like a gutter tile, as that of Cumin. Moreover, there is a difference in colour, for ſome ſeeds bee white, others blacke: in hardneſſe alſo and ſoftnes; for ſome be harder or ſofter than others. Some
B ſeeds at every branch of the plant, are contained within cods or bladders, as we may ſee in Raddiſh, Senvie, and Turneps or Rapes. The ſeeds of Perſely, Coriander, Dill, Fennell, and Cumin, grow naked & bare. But that of the Bleet, the Beet, Orach and Baſil, is enclоſed in a huske or hull. Lectuce ſeed lieth within a downe. As touching Baſill aforeſaid, nothing fructifieth more than it: and to the end that it may come up in more plentie and abundance, they ſay it ſhould be ſowed with maledictions and ill words; for the more that it is curſed, the better it will ſpeed and proſper; yea, and when it is ſowed, the mould of the bed muſt be patted and rammed downe in manner of a pavement. And more particularly, they that ſow Cumin, pray to God that it may never come up. Such ſeeds as lie within an huske, hardly come to be drie and ripe therin: but Baſil ſeed eſpecially, and Gith or Nigella Romana. But they muſt be all throughly dried before they be ſee-
C dow and fruitfull. This is generall in all hearbes throughout, that they will thrive and grow the better, if their ſeed be ſowed by heapes one upon another, than ſcattering. And certainely both Leekes ſeed is ſowne and Garlicke cloves ſet in that wiſe, namely, bound up and tied together in ſome clouts or rags wherein they be lapped. As for Perſely ſeed, againſt it ſhould be ſowne, there would bee an hole made with a little wooden dibbil or pin, and therein it muſt bee put with ſome dung after it. Furthermore, all garden hearbs come up either of ſeed and cloves ſet; or els of ſlips pulled from the mother-plant. Some grow of ſeed and ſprigs both, as Rue, Origan, and Baſill: for even this hearbe alſo laſt named will abide cutting when it is come to be one handbreadth, or a ſpan high; and thoſe cuttings will grow if they be planted. There bee that are maintained by root and ſeed both, as Onions, Garlicke, and thoſe which have bulbous roots: likewiſe, all ſuch as when
D they have borne yearely, leave a root behind them ſtill in ſtrength and vertue. Of ſuch as grow of roots replanted, their roots continue long and braunch much, as wee may ſee in the bulbes, in Chibbols and ſea-Onions. Others put out braunches ſufficient, but not from the head or root, as Perſeley and Beets. All hearbes for the moſt part, do ſpring and ſhute againe, if their ſtalke be cut off; unleſſe it be thoſe that have a ſmooth ſtem. And this is moſt ſeene in Baſill, Raddiſh, and Lectuce, the ſtems whereof are cut for many purpoſes. And as for Lectuce, men hold, That the latter Spring thereof, when the firſt is gone, is the ſweeter. Certainely, Raddiſhes eat the more pleaſantly, if their leaves bee cropt off before the maiſter ſtem or ſpire be growne big. And this alſo we obſerve in Rapes or Turneps: for if you ſtrip them alſo from their leaves and cover them over head with earth, yet will they grow all Winter and continue till Summer following. Touching
E Baſill, Sorrell, red Porret or Bleets, garden Creſſes, Rocket, Orach, Coriander, they are all of one ſort, & ſingular in their kind: for ſow them where you will, they be the ſame ſtill, neither are they better in one place than in another. It is a common received opinion, that Rue will grow the better if it bee filtched out of another mans garden: and it is as ordinarie a ſaying, that ſtollen Bees will thrive worſt. Some hearbs there be which come without ſowing or ſetting, as wild Mint, Nep, Endive, and Peniroyall. But howſoever there be but one ſingle kind of thoſe before rehearſed, yet on the contrarie ſide, there be many ſorts of others, whiche we have alreadie ſpoken of, and will write more hereafter, and principally of Ach or Perſeley.

Chap. VIII.

F *Of Garden hearbes which ſerve for to ſeaſon our meats: their divers natures, their ſundrie kinds and ſeverall hiſtories related, to the number of* 36.

FOr, that kind of Ach which groweth of it ſelfe in moiſt grounds with *one leafe, and is not rough, but ſmooth and plaine, is called in Greeke Heleoſelinon, *i.* Smallach. Againe, there is ano-

*μονόφυλλον. For ſo it ſhould ſeeme that *Plinie* read it in *Theophraſtus*: wheras indeed it is μανόφυλλον, *i.* with leaves growing thin.

another ſort, with more leaves, reſembling Smallach aforeſaid, but that it commeth up in drie places, and this the Greekes named Hippoſelinon, *i.* Aliſanders. A third there is beſides found in mountaines, named by them thereupon Oreoſelinum, *i.* Mountaine Ach, or Perſely of the hils: it beareth leaves like Hemlocke, and a little ſlender root: the ſeed reſembleth Dill ſeed very much, but only that it is ſmaller. And as for the garden Ach, commonly called Perſeley, there be many kinds therof, differing one from another: firſt in leafe, whereby you ſhall have ſome leafed thicke and full, and the ſame jagged and curled: others thinner, & thoſe alſo more plain, ſmooth and broad. *Item*, In ſtalke, which in ſome is more groſſe or thin than in other: in one kind white, in another purple, and in a third of ſundrie colours. G

Of Lectuce, the Greeks have ſet downe three kinds: whereof the firſt riſeth up with ſo large and broad a ſtalke, that by their report, little garden wickets were commonly made thereof, in partitions betweene quarter and quarter. And yet the leafe of this Lectuce is not much bigger than others that bee common and ſerve for pot-hearbs: the ſame alſo paſſing narrow, by reaſon that all the nutriment is otherwiſe ſpent in the maine ſtem. The ſecond hath a round ſtalke: the third is the broad flat Lectuce which ſetleth neare the ground, called Laconicon, or the Lectuce of Lacedæmon. But other writers have deſcribed the diſtinct kinds thereof by their colour, and the ſundrie ſeaſons wherein they be ſet: for (ſay they) there be blacke Lettuces, the ſeed whereof ought to be ſowed in Ianuarie: there be white alſo, and ſuch would be ſowed in March: & there are a third ſort which be red, and the fit time of their Seednes is the moneth of Aprill. And according to thoſe authors, all the ſort of them are to bee remooved in young plants, when they have growne two moneths. Howbeit, thoſe Herbariſts who have looked farther into the knowledge of Simples, add more kinds yet unto the other, to wit, the purple, the criſpe or curled, the Cappadocian, and the Greekiſh Lettuce. As for theſe of Greece, they are taller in ſtem than the reſt, and broader withall; beſides, their leaves be long and narrow, like to thoſe of Endive or Cichorie. The worſt kind of all is that, which the Greeks by way of reproofe and reproch for their bitterneſſe, tearme Picris. Yet is there another diſtinct kind of the blacke Lectuce, which for the plentie that it yeeldeth of a milkie white juice procuring drowſineſſe, is tearmed Meconis; although all of them are thought to cauſe ſleepe. In old time, our auncetors knew no other Lettuce in Italy but this alone, and thereupon it tooke the name in Latine of Lactuca. The purple Lectuce which hath the biggeſt root, they name Cæciliana: but the round kind with ſmalleſt root and broad leaves, is called * Aſtylis, [*i.* the chaſt Lectuce, or the civile Lectuce:] howbeit, ſome give it the name of Eunuchij, becauſe of all others it cooleth luſt moſt, and is an enemie to the ſports of *Venus*. And to ſay a truth, all Lectuces are by nature refrigerative, and doe coole the bodie; and therfore be they eaten ordinarily in Summer: for they pleaſe the ſtomack when it is enclined to loath meat, and procureth good appetite. Certes, reported it is of *Auguſtus Cæſar* late Emperour of famous memorie, that he eſcaped a daungerous diſeaſe, and was recovered by the means of Lectuce, whereunto he was directed by the diſcreet counſell of *Muſa* his Phyſician. And whereas in times paſt, folke preciſely forbare to eat Lectuce, now there is no doubt or ſcruple at all made therof; nay they are ſo far from abſtinence that way, that it is a meat generally received and commended: inſomuch as they have deviſed to keepe it in the ſyrrup of Oxymel, all winter long, for to have it readie and ever at hand: yea and more than ſo, men are verely perſuaded, that Lectuce will encreaſe good blood. Over and beſides all the ſorts of Lettuce before ſpecified, there is yet another kind named in Latine Caprina, as one would ſay, the Goats Lectuce, whereof I purpoſe to ſpeake more at large among other medicinable hearbs. As touching the wild Lectuce called Cilician, ſee how it is crept apace into the garden after it came once to be knowne, and is commended as exceeding good among other hearbs there ſown and planted: the leafe reſembleth the Cappadocian Lectuce, but that it is jagged & broader than it. As for Endives and Cichories, I cannot tell what to make of them: for neither can they be truly ſaid a kind of Lectuce, nor yet raunged well among other hearbs. More unpatient they are and fearfull of winter, than Lectuces, and withall carrie an unpleaſant ſtrong taſt: howbeit their ſtalks are no leſſe acceptable than they. Their young plants uſe to be ſet in the beginning of the Spring, but tranſlated afterwards and replanted in the latter end thereof. There is a certain wild and wandring Endive, which the Ægyptians call Cichorie, whereof I meane to diſcourſe more amply in another place. There hath been a deviſe lately come up to condite and preſerve as well the ſtems as the leaves of all Lectuces for the winter time, in pitchers and pots, within ſome appropriat H I K L M

* See *Cælius Rhodiginus* 27 booke and laſt chap. *antiqu. Lectionum*: and let him tell you, why women call this Lectuce, *Aſtylis*.

A propriat liquor; as alſo to dreſſe and ſeeth them young, freſh, and greene, in a kind of broth or browiſſe, and ſo ſerve them up between two platters. And yet where the ground is rich and good, well watered and holpen with dung, Lectuce may be ſowed at all times of the yeare: for within two months they will grow to be good big plants, and in as little ſpace come to their full maturitie and perfection. Howbeit, the true time and ordinarie ſeaſon, is to ſow their ſeeds about the mids of December, when the daies begin to lengthen, and then to remoove their plants at the comming of the Weſterne wind Favonius in Februarie: or els to ſow in that wind, and to replant in March about the Spring Æquinox. White Lectuce of all other, can beſt away with the winter. All Garden-hearbs love moiſture, and muck they love as well, Lectuce eſpecially; & yet I muſt needs ſay, that Endive more than it. Some gardiners there bee, that thinke it a great point
B of cunning to beſmeare the roots of Lectuce plants and other ſuch hearbs with dung, when they are ſet; or after they be bared at the root within the ground, to caſt in the mould againe and fill up the place ſo ſoone as they be greaſed (as it were) with mucke at the root. Others there be, who practiſe another feat with them, to make them cabbage the better and grow faire and big, by cutting them up cloſe to the ground when they are come once to be halfe a foot high, and then bedawbing them with greene ſwines dung. It is thought, that white Lectuce come onely of white ſeed; and yet that is not ſufficient, unleſſe there be ſome ſea ſand taken freſh from the ſhore and laid about the heart of the plant where the leaves put forth firſt, and ſo reared and heaped up to the mids; and then to take order that the leaves growing over them afterwards, be tied faſt unto them.

C Of all Garden-hearbs, Beets are the lighteſt. The Greeke writers make two kinds thereof, in regard of the colour; to wit, the blacke Beets, and the whiter, which they preferre before the other, although it be very ſcant and ſparie of ſeed: theſe alſo they call the Sicilian Beets, and for their beautifull white hew and nothing els, they eſteeme them above Lectuce. But our countreymen here in Italie put no other difference betweene Beets, but in reſpect of the two ſeaſons when they be ſowed, namely in the Spring, and Autumne; whereof we have theſe two ſorts, the Spring Beets, and the Autumnall; and yet they be uſually ſowne in Iune alſo. This hearb likewiſe is ordinarily remooved in the plant, and ſo replanted or ſet againe: it loveth beſides to have the roots medicined with mucke, as well as the other aboveſaid, yea and it is very well content with a moiſt and wateriſh ground. The roots as well as the leaves or herbage thereof, uſe to bee
D eaten with Lentils & Beans: but the beſt way to eat them, is with Senvie or muſtard, for to give a taſt & edge as it were to that dull and wallowiſh flatneſſe that it hath. Phyſicians have ſet down their judgement of this hearb, That the roots be more hurtfull than the leafe: and therefore being ſet upon the bourd before all perſons indifferently, as well the ſound as the ſicke and craſie, yet many a one maketh it nice and ſcrupulous once to taſt therof; and if they doe, it is but ſlightly for faſhion onely, leaving the heartie feeding thereupon to thoſe rather that be in health and of ſtrong conſtitutions. The Beet is of two divers natures and qualities: for * the herbage or leafe hath one, and the bulbs comming from the head of the ſtem, another: but their principall grace and beautie lieth in their ſpreading and breadth that they beare as they cabbage. And this they come unto (as the manner is of Lectuces alſo) by laying ſome light weight upon the
E leaves, when they begin once to gather into a ſtalke and ſhew their colour. And there is not an hearb throughout the Garden, that taketh up a greater compaſſe with fuellage than doth the Beet: for otherwhiles you ſhall ſee it to ſpread it ſelfe two foot every way; whereunto the goodneſſe and nature of the ſoile is a great helpe. The largeſt that be knowne of theſe Beets are thoſe which grow in the territorie about Circeij. Some hold opinion, that the only time to ſow Beets, is when the Pomegranat doth bloſſome: and to tranſplant them ſo ſoon as they have five leaves. A wonderfull thing to ſee the diverſitie in Nature of theſe Beets, if it be true; namely, that the white ſhould gently looſen the belly and make one ſoluble, whereas contrariwiſe the blacke doe ſtay a flux and knit the bodie. It is as ſtraunge alſo to obſerve another effect thereof: for when the Colewort hath marred the taſt of wine within the tun or ſuch like veſſell, the only ſavour and
F ſmell of Beet leaves ſteeped therein, will reſtore and fetch it againe.

As touching the Beets, as alſo Colewoorts, which now beare all the ſway and none but they in Gardens; I do not find that the Greeks made any great account of them: and yet *Cato* highly extolleth Coules, and reporteth great wonders of their vertues and properties, which I meane to relate in my treatiſe of Phyſicke. For this preſent, you ſhall underſtand, that he putteth down

* *Olus*, which word *Plinie* uſeth much for Beets.

*For some resemblance of Parsley.

three kinds of them: the first, that stretcheth out broad leaves at full, and carieth a big stem: the G
second, with a crisped and frizled leafe, the which he calleth* Apiana: the third is smooth, plain, and tender in leafe, and hath but a little stalke; and these are of no reckoning at all with *Cato*. Moreover, like as Coleworts may be cut at all times of the year for our use, so may they be sown and set all the yeere long: and yet the most appropriat season is after the Æquinox in Autumne. Transplanted they be when they have once gotten five leaves. The tender crops called Cymæ, after the first cutting, they yeeld the Spring next following: now are these Cymæ nothing els but the young delicat tops or daintier tendrils of the maine stem. And as pleasant and sweet as these crops were thought to other men, yet *Apicius* (that notable glutton) tooke a loathing of them: and by his example *Drusus Cæsar* also cared not for them, but thought them a base and homely meat; for which nice and daintie tooth of his, he was well checked and shent by his father *Tyberius* the Emperour. H
After this first crop or head is gone, there grow out of the same Colewort other fine colliflories (if I may so say) or tendrils, in Summer, in the fall of the leafe; and after them, in winter: and then a second Spring of the foresaid Cymæ or tops against the Spring following, as the yeare before: so as there is no hearb in that regard, so fruitfull, untill in the end her owne fertilitie is her death; for in this manner of bearing she spends her heart, her selfe and all. There is a third top-spring also at midsummer about the Sunstead, which (if the place be any thing moist) affourdeth young plants to be set in summer time; but in case it be over-drie, against Autumne. If there bee want of moisture and skant of mucke, the better tast Coleworts have: if there be plentie and to spare of both, the more fruitfull and ranke they are. The only muck and that which agreeth best with Coleworts or Cabbages, is Asses dung. I am content to stand the I
longer upon this Garden-wort, because it is in so great request in the kitchin, and among our riotous gluttons. Would you have speciall and principall Colewoorts, both for sweet tast and also for great and faire cabbage? first and foremost, let the seed bee sowne in a ground througly digged more than once or twice, and well manured: secondly, see you cut off the tender springs and young stalkes that seeme to put out far from the ground; or such as you perceive mounting too ranke and over-high from the earth: thirdly be sure to raise other mould in manner of a banke up to them, so as there peepe no more without the ground, than the very top. These kind of Coleworts is fitly called Tritianum, for the threefold hand and travaile about them; but surely the gaine will pay double for all the cost and toile both. Many more kinds there bee of them, to wit, that of Cumes, which beareth leaves spreading flat along the ground, and opening in the K
head. Those of Aricia, bee for heigth no taller than they, but rather more in number than for substance thinner and smaller: This kind is taken for the best and most gainfull, because under every maine leafe in manner, it putteth forth other young tendrils or buds by themselves, which are good to bee eaten. The Colewort Pompeianum (so called of the towne Pompeij) is taller than the rest, rising up with a small stem from the root; howbeit among the leaves it groweth to more thickneſſe. These leaves braunch out but here and there, and are in comparison of others narrower; howbeit much set by for their speciall tenderneſſe, whereby they are soon sodden and dressed: and yet cold weather they cannot endure; whereas on the other side, the Coleworts of Bruzze or Calabria, like the best in winter, and bee nourished with the hard season: leaves they L
have exceeding great and large, but their stalks are but small: and as for tast, they be sharp and sower. The Sabellian Coles, what curled and ruffed leaves they carrie, it is a wonder to see: so thicke they are besides, that they rob the very stem of their nutriment, which thereby is the smaller: howbeit of all others they be reputed the sweetest. Long it is not since there came from out of the vale of Aricia (where sometimes there was a lake, and a tower standing upon it, remaining yet at this day to be seene) a kind of Cabbage-cole, with a mightie great head and an infinite number of leaves, which gather and close round togither; and these Coles we in Latine call Lacuturres, of the place from whence they come. Some Coleworts there be, which stretch out into a roundle; others againe extend in breadth, & be very full of fleshie brawnes. None, cabbage more than these, setting aside the Tritian Coleworts beforenamed; which are known otherwhiles to beare a head a foot thicke, and yet none put foorth their Cymes or tender buds more than M
they. Moreover, this would be noted, That howsoever all kinds of Coleworts eat much sweeter for being bitten with the frost, yet if there be not good heed taken in cutting off their head or tender crops and buds, so that the wound come not neare the heart and pith, (and namely, by cutting them aslope and byas in manner of a Goats foot) they will take much harme hereby.

A Such as be reſerved to bear ſeed, ought not to be cut at all. They alſo are not without their grace and commendation, which never paſſe the bigneſſe of a greene and ordinarie plant, and ſuch ſmall Coles are called Halmyridia, for that they grow not elſewhere but upon the ſea coaſts: and becauſe they will keepe greene, proviſion is made of ſuch for to ſerve in long voyages at ſea: for ſo ſoone as they bee cut up, before they touch the ground, they be put up into barrels where lately oile hath been, and thoſe newly dried againſt the time, and ſtopped up cloſe that no aire at all may enter in, and therein be they preſerved. Some there be, who in remooving the young plants, lay under their roots, Riek and Sea-weeds, or els bruiſed and powdred nitre, as much as a man may take up with three fingers, imagining thereby that they will the ſooner come to maturitie. Others againe take the ſeed of Trifolie and Nitre ſtamped togither, which they ſtrew upB on the leaves for the ſame purpoſe. [And as for Nitre, it is of this nature, to make them looke greene ſtill although they were ſodden;] or els they uſe to boile them after *Apicius* his faſhion, namely, to ſteepe them well in oile and ſalt mingled togither, before they be ſet upon the fire for to be ſodden.

Moreover, there is a way to graffe hearbs alſo as well as trees, namely, by cutting off the yong ſions that ſpring out of the ſtalke, and therein to inoculate as it were the ſeed of another plant, within the pith or marow thereof. This alſo may be practiſed upon wild Cucumbers. Over and beſides, there is a kind of wild Woorts growing in the fields, called Lapſana, much named and renowmed by occaſion of the ſonets & carols chanted in the ſolemnitie of *Iulius Cæſar* the Emperours triumph, and eſpecially of the merrie rimes and licentious broad jeaſts toſſed by his ſolC diers, who at every ſecond verſe caſt in his teeth, that in Dyrrhachium they lived of nothing els but of thoſe Woorts: noting indeed by way of cavill and reproach, his niggardiſe in rewarding them ſo ſlightly for their good ſervice. Now was this Lapſana a kind of wild Colewort, which they did eat of in ſtead of the fine and daintie tendrils and buds of the garden Coles.

As touching Sperages, there is not an hearb in the garden, whereof there is ſo great regard and care taken, as of them. Concerning their firſt originall and beginning, I have ſpoken at large in the treatiſe, Of the manner how to order the * wild of that kind, and to entertaine them in our gardens: as alſo how *Cato* willed us to ſow and plant them in plots of Reeds and Canes. Now there is a middle ſort of theſe Sperages, not ſo civile and gentle as the Aſparagi of the garden, and yet more kind and mild than the Corrudæ of the field: theſe grow every where abroad D even upon the mountains; and the champion countrey of high Almaine is overſpread and full of them: whereof there goes a pleaſant ſpeech and merrie conceit of *Tyberius Cæſar* the Emperour, namely, That there grew an hearb in Almaine very like to the Garden Sperage. For as touching that which commeth up of it ſelfe in Neſis, an Iſland of Campaine, it is thought the beſt ſimply of all others, without compariſon. The Garden Sperages be planted from the knots bunching togither within the ground, named Spongiæ, which eaſily may be replanted; for ſurely an hearb it is that carrieth a mightie head or cluſter as it were of roots, and the ſame putteth foorth ſpurns every way from it of a great depth into the ground. They ſend out at firſt certaine greene ſpurts or buds peeping forth of the ground, which growing to a ſtem in proceſſe of time riſe ſharpe in the top, and then are they chamfered and devided into certain muſculous braunE ches that ſpread abroad. This hearb may be ſown alſo of ſeed. *Cato* tooke not more pains about any other hearb, nor emploied greater diligence in the deſcription thereof, than he did in it. It is the very laſt thing that he treateth of in his booke, wherby it may appeare, that the man came all upon a ſodain and newly to the knowledge of that hearb, and the ordering of it. Hee giveth order, *Imprimis*, That the plot wherein they are to be ſowne, be moiſt, fat, and well digged. *Item*, That they be ſet halfe a foot every way aſunder one from another, & in no wiſe the place troden downe with ones foot: moreover, that two or three ſeeds be put togither in a hole, made before with a dibble directly by a line: for in thoſe daies they ſet them onely of ſeed. *Item*, That this would be done about mid-March, which is the proper ſeaſon therefore. *Item*, That they have their fill of dung; That they be kept cleane with often weeding: but in any caſe, That great heed F be taken in plucking up the weeds, that the tender buds or crops new knit and appearing above ground, be not knapt off. For the firſt yeere, hee would have them in winter time to be covered with ſtraw and litter, and ſo defended againſt the froſt and cold weather: alſo during the Spring enſuing, to be opened at the root, ſarcled and well weeded. In the third yeere, by his rule, they ought to be burned in the Spring time; and the ſooner that the ground is thus burned, the better

* *Corrudæ.*

will they come up againe and in greater plentie: which is the cauſe, that they like and proſper beſt in plots ſet with Canes and Reeds: for ſuch deſire to be burnt betimes in the yeere. Moreover, he giveth another precept, That they muſt not be ſarcled, nor have the earth opened & laid hollow about them, before their buds or tops be above ground to be ſeene, for feare leaſt in the ſarcling, the roots take harm therby, either by raſing or ſhaking them untill they be looſe. From which time forward, if a man would gather any of the ſaid buds or yong ſprings, for ſalad or other uſe, they ought to be plucked and ſlipped from the root; for otherwiſe, if they be broken & knapt off in the mids, the root will preſently put forth many unprofitable ſprouts, which will ſuck away all the heart and kill it in the end. Slive and plucke it you may in manner aforeſaid, untill it ſpindle and run to ſeed; which commonly beginneth to be ripe in the Spring, and then it muſt bee ſet on fire, as is beforeſaid: and then once againe, ſo ſoone as new buds and tendrons appeare above ground from the root, they muſt be ſarcled, bared, and dunged afreſh. Now after it hath growne in this manner nine yeeres, ſo as by this time it is waxen old, the roots muſt be taken up, and then replanted againe in a peece of ground well digged and as throughly dunged. Then (I ſay) ought the ſmall roots called Spongiæ in Latin, to be ſet again, a foot diſtant one from another. Furthermore, *Cato* ordaineth expreſſely by name, That ſheeps dung ſhould be uſed for that purpoſe, becauſe any other would breed ſtore of weeds. And verily there was never knowne any other thing practiſed or aſſaied afterwards, to more gaine and benefit about this Garden-hearb, unleſſe it were this, That about the Ides or mids of Februarie, ſome have let the ſeeds of Sperage lie well ſoked in dung, and then ſowed the ſame by heaps in little trenches or holes made for the purpoſe: after which, when the roots are woven and knit one within another into a knot, the ſpurns ſhooting from them they plant after the Æquinox in Autumne following, a foot aſunder: by which means they will continue bearing plenteouſly for ten yeares togither. For to breed and maintain theſe garden Sperages, there is no better ſoile than the gardens of Ravenna, from whence we have the faireſt of all other. As for the hearb named in Latin Corruda, I have written heretofore of it: and I underſtand thereby, the wild Sperage, which the Greekes call Orminum and Myacanthon: howbeit there be, who give it other names. Finally, I read of certaine Sperages which will engender and grow of Rams hornes beaten or ſtamped, and then put into the ground.

A man would thinke that I had diſcourſed alreadie of all ſuch Garden-hearbs as were of any price and regard: but that there remaineth one thing yet behind, whereof the greateſt gaine of all other is raiſed, and yet me thinks I cannot write thereof, but bee abaſhed to raunge it among the good hearbs of the Garden; and that forſooth is our Thiſtle: howbeit this is certain (to the ſhame be it ſpoken of our wanton and waſting gluttons) that the Thiſtles about Carthage the great, and Corduba eſpecially, coſt us ordinarily ſix thouſand thouſand Seſterces to ſpeake within compaſſe. See how vaine and prodigall we be, to bring into our kitchin and ſerve up at our table, the monſtruoſities of other nations, and cannot forbeare ſo much as theſe Thiſtles, which the very aſſes and other four-footed beaſts, have wit enough to avoid and refuſe for pricking their lips and muzzles. Well, ſince they be grown into ſo great requeſt, I muſt not over-paſſe the gardinage to them belonging, and namely, how they be ordered two manner of waies; to wit, replanted of young ſet or roots in Autumne, and ſowed of ſeed before the Nones of March. As for the plants beforeſaid, they ought to be ſlipped from it, and ſet before the Ides or mids of November in any hand: or els if the ground be cold, we muſt ſtay untill Februarie, and then be doing with them about the riſing of the Weſterne wind Favonius. Manured ywis it ought to bee and dunged (I would not els) ſo faire and goodly an hearb it is; and ſo forſooth (and it pleaſe you) they proſper the better and come on trimly. They are condite alſo and preſerved in vinegre (or els all were mard) in delicat life honey, ſeaſoned alſo and beſpiced (I may ſay to you) with the coſtly root of the plant Laſer-woort, yea and with Cumin; becauſe wee would not be a day without Thiſtles, but have them as an ordinarie diſh all the yeere long.

This is meant of Artichokes.

As for the reſt of Garden-hearbs behind, they need no long diſcourſe, but a light running over them may ſerve well enough. Firſt and foremoſt men ſay, That the beſt ſowing of Baſill, is at the feaſt * Palilia: but ſome are of mind, that Autumne is as good: and they that would have it done in winter, give order to infuſe and ſoke the ſeed firſt in vinegre. Rocket alſo and Garden Creſſes, are not daintie to grow, but be it winter or ſummer, they will ſoon come up and proſper at all times. But Rocket of the twaine, ſtands more at defiance with winter, and ſcorns all his frowning

* 11. Cal. May, i. 21 of Aprill.

A ning lookes and cold weather; as being of a contrarie nature to Lectuce, for it ſtirreth up fleſhly luſt: and therefore commonly it is joyned with Lectuce in ſalads, and both are eaten togither; that the exceeding heat of the one mixed with the extream coldneſſe of the other, might make a good marriage and temperature. Creſſes tooke the name in Latin * Naſturtium, *a narium tormento*, as a man would ſay, Noſe-wring, becauſe it will make one wryth and ſhrinke up his noſthrils: which is the reaſon, that the word is growne into a proverb, when wee would ſignifie a thing which will put life into one that is dull and unluſtie. In Arabia, the Creſſes (by report) proove to a wonderfull bigneſſe. Rue alſo is ſowed uſually in Februarie when the Weſtern wind Favonius bloweth, and ſoone after the Æquinox in Autumne. It cannot away with winter, for it brooketh not cold or rain, nor moiſt ground, neither will it abide mucke: it liketh well to grow
B in drie places, and ſuch as lie faire upon the Sun-ſhine; but a clay ground which is good for bricke and tile, that is alone for it and beſt of all other: it delighteth in aſhes, and therewith is it fed and nouriſhed; inſomuch as they uſe to blend aſhes and the ſeed togither, for to keepe away the cankerworme and ſuch like. Certes we find, that in old time Rue was in ſome great account and eſpeciall reckoning above other hearbs: for I read in auncient hiſtories, That *Cornelius Cethegus* at what time as he was choſen Conſull with *Quintius Flaminius*, preſently upon the ſaid Election, gave a largeſſe to the people of new wine aromatized with Rue. The Figtree and Rue are in a great league and amitie, inſomuch as this hearb, ſow and ſet it when and where you will, in no place proſpereth better than under that tree: for planted it may be of a ſlip or ſprig. Now if the ſame be put into a beane which hath a hole pierced or bored through, it will doe far bet-
C ter; by reaſon that the beane claſping the ſet cloſe and uniting thereunto her owne ſap and moiſture, cheriſheth it therewith and makes it come apace: moreover, it will propagat and ſet it own ſelf, for let the top of any of her branches be bent downward, ſo as it may but touch the ground, it will preſently take root. Of the ſame nature it is, that Baſill, but that Rue is ſomewhat later ere it come up, and groweth not ſo faſt. When Rue is come to bee of any ſtrength, there is untoward ſarcling and weeding of it; for if it be handled, it will raiſe bliſters upon a mans fingers, unleſſe the hands be well gloved, or defenſed with oile. The leaves alſo of Rue are kept and preſerved, being made up into little knitches or bunches.

Now as touching Ach or Parſley, the manner is to ſow it immediatly after the Spring Æquinox in March, but the ſeed would be firſt bruſed and beaten a little in a mortar: for ſome are per-
D ſuaded, that by this means it groweth thicker and more criſpe or curled: which it will doe likewiſe, in caſe after a bed be ſowed therewith, it be troden upon with mens feet, or beaten downe with a roller or cylindre. This peculiar propertie hath Perſley, That it will chaunge the colour. It was an auncient cuſtome in Achaia, to doe honour unto this hearb, by crowning thoſe that went away with victorie and wan the prize in the ſolemne tourneys and ſacred games Nemei, with a chaplet of Perſley. As for Mint, men uſe to ſet it at the ſame time, of a young plant, ſo ſoone as they ſee it is ſpurt and come up: but if it have not ſprung, yet they let not to plant the ſpurnes of the root, knotted into an head within the ground in manner of the Spongiæ in Sperage beforeſaid. This hearb taketh no great joy in moiſt grounds: all Summer it looketh greene and freſh, but in winter it hath a hempen hew. A wild kind there is of Mint, named in Latin Mentaſtrum,
E which will encreaſe by propagation or couching in the ground, as well as vine braunches: and ſo willing is it to take, that it makes no matter which end of a ſlip bee ſet downward; for at the wrong end it will come as well as at the other. Mint in the Greeke tongue hath chaunged the old name, by occaſion of the ſweet * ſmell that it carieth, whereas before time it was called Mintha, whereof we in Latin derived our name Mentha. A pleaſant hearb this is, and delectable to ſmell unto, inſomuch as you ſhall not ſee a husbandmans bourd in the countrey, but all the meats from one end to the other be ſeaſoned with Mints. If it be once ſet or ſowne, and have taken to a ground, it will continue there a long time. It reſembleth much the hearb Penyroiall, the nature whereof (as I have often ſhewed) is to blow her floures againe (upon the ſhorteſt day of the yeer) even as it hangeth prickt upon fleſh in the butcherie. Much after one ſort are kept and preſerved
F for ſawce (as if they were of the ſame kind) Mint, Penyroiall, and Nep: but above all, to a weake and peeviſh ſtomacke, Cumin agreeth moſt and is the beſt to get an appetite. It hath a qualitie to grow with root very eb, and ſcarſely taketh any hold of the earth, coveting to be aloft. In hot grounds and ſuch eſpecially as be rotten and mellow, it would be ſown in the midſt of the Spring. There is a ſecond ſort therof growing wild, which ſome call Cumin Ruſtick, others Thebaicke,

* In Greeke alſo ῥαφανος, quaſi ῥαφὺς φαρυς, quia caput tentat, becauſe it troubleth the head with exceſsive heat: vel potius, ἀπὸ τῆ ῥαφίδι, qui cordatos & prudentes facit: therfore there went a by word or proverbe in Greeke, applyed to a dull, fooliſh, and blockheaded fellow, ῥαφάνου ἔδωκε; Go, eat ſome Creſſes, learne more wit.

* ἐύοσμος, i. odoriferous or ſweet ſenting.

which being bruſed or beaten into powder, and drunke in water, is ſingular good for the paine of the ſtomacke. The beſt Cumin in our part of the world, which is Europe, commeth from Carpetania: for otherwiſe the greateſt name goeth of that in Æthyopia and Affricke. And yet ſome there be who prefer the Cumin of Ægypt before all. G

But *Aliſanders, which ſome Greekes call Hippoſelium, others Smyrneum, is of a ſtraunge and wonderfull nature above all other hearbes: for it will grow of the very liquor or juice iſſuing forth of the ſtalke. It may be ſet alſo of a root. And indeed, they that gather the foreſaid juice, uſe to ſay, that it hath the very taſt and relliſh of Myrrhe: and by *Theophraſtus* his ſaying, it came firſt of Myrrhe ſet into the ground. The old writers ordained, that Aliſanders ſhould bee ſet or ſowed in ſtonie grounds, without tending or looking unto, near to ſome *mud wall. But now in our daies it is planted in places digged and delved over, once or twice: yea, and at any time from the blowing of the weſterne wind Favonius in Februarie, untill the later Æquinox in September be paſt. H

*A corrupt word from *Olus atrum*: as if one would ſay, *Oluſatres*. Some take this for Lovach.

**Juxta maceriam*, whereupon ſome Apothecaries name it *Maceranium*.

Capres likewiſe are ſet and ſowed in drie places eſpecially: but the bed muſt bee digged in ſome low ground and laid hollow, environned round about with bankes, and thoſe raiſed with a groundſell of ſtone worke, otherwiſe it would bee raunging abroad and overſpread whole fields, and make the ground barren and unfruitfull. It flouriſheth in Summer, and continueth green untill the occultation or ſetting of the Brood-hen ſtar Vergiliæ: and ſandie ground is moſt familiar and agreeable to it. Touching the defects and imperfections of that kind which groweth beyond ſea, I have ſaid ynough among the ſhrubs and plants that be ſtraungers.

The Caraway alſo is a ſtraunger, as may appeare by the name of Caria, the native countrey thereof: it beareth one of the principall ſeeds that come into the kitchin. It careth not much where it is ſowne or planted, for it will grow in any ground, as well as the Aliſanders beforenamed. Howbeit, the beſt commeth out of Caria, the next to it in goodnes, we have from Phrygia. I

As for Loveach or Liviſh, it is by nature wild and ſavage, and loveth alone to grow of it ſelfe among the mountaines of Liguria, whereof it commeth to have the name Liguſticum, as being the naturall place beſt agreeing to the nature of it. Set or ſowed it may be in any place whereſoever: howbeit, this that is thus ordred by mans hand hath not the like vertue as the other, although it bee in taſt more pleaſant, and ſome call it Panax or Penace. Howbeit, *Cratevas* a Greeke writer, calleth the wild Origan or Cunila Bubula, by that name. But all others in manner, attribute the name of Conyza or Conyzoïdes to Cunilago, *i.* Fleabane Mullet: and of Thymbra, *i.* Winter Savorie, to Cunila, *i.* garden Savorie; which among us hath another name in Latine, to wit, Satureia, much uſed in ſauces and ſeaſoning of our meats. K

This Savorie is commonly ſowne in the month of Februarie, and hath no ſmall reſemblance of Origan, inſomuch, as they are never both uſed at once in ſauce or ſallads; their vertues & operations be ſo like. And yet the Ægyptian Origanum is preferred before the ſaid Savorie.

To come now to Lepidium, *i.* Dittander or Pepperwort, it was ſometime a ſtraunger alſo with us here in Italie. It is uſually ſowne after mid Februarie when the Weſterne wind Favonius hath plaied his part: afterwards when it hath put forth braunches, it is cut downe cloſe to the ground, and then it is laid bare and ſarcled, and the ſuperfluous roots cut away, & ſo in the end cheriſhed with mucke. Thus muſt it be ſerved the two firſt yeares. For afterwards they uſe the ſame in branches at all times, if the cruell and bitter Winter kill them not; for ſurely this hearbe is moſt impatient of cold. It groweth a good cubite in height, bearing leaves like to Lawrell, and the ſame ſoft and tender. But never is it uſed in meat without milke. L

Now for Gith or Nigella Romana, as it is an hearbe that groweth for the paſtrie, to fit the Bakers hand; ſo Anniſe and Dill are as appropriate to the kitchen for Cookes, and the Apothecaries ſhop for the Phyſician.

Sacopenium likewiſe is an hearbe growing verely in gardens, but is uſed in Phyſicke onely.

Certaine hearbes there be that accompanie others for good fellowſhip, and grow with them, as namely Poppie: for commonly ſowne it is with Coleworts, Purcellane, Rocket, and Lectuce.

Of garden Poppies there be three kinds, firſt the white: whereof the *ſeeds in old time being made into Biskets or Comfits with honie, were ſerved up as a banketting diſh. The ruſticall peaſants of the countrey were wont to guild or glaze (as it were) the upper cruſt of their loaves of bread with yolkes of egs, and then to beſtrew it with Poppie ſeed, which would cleave faſt unto it, having firſt underlaied the bottome cruſt with Ammi, or Anniſe ſeed and Gith: and then they put them into the oven being thus ſeaſoned; which gave a commendable taſt to their bread M

*This Iunket of Conceit was called *Coctum* by *Tertullian* and *Feſtus*.

when

A when it was baked. There is a ſecond kind of Poppie called Black: out of the heads or bols wher-
of, a white juice or liquor iſſueth by way of inciſion, like unto milke, and many receive & reſerve
it carefully. The third kind, which the Greekes name *Rhœas, our countreymen in Latine call *Corne Roſe.
the wandering or wild Poppie. It commeth up verely of the owne accord, but in corne fields a-
mong Barley eſpecially, like unto Rocket, a cubite high, with a red floure that ſoone will ſhed and
fall off, whereupon it tooke that name of Rhœas in Greeke. Touching other kinds of Poppie
growing of themſelves, I purpoſe to ſpeake in the Treatiſe of Phyſicke and medicinable hearbes.
Meane while this cannot be forgotten, that Poppies have alwaies, time out of mind, been high-
ly regarded and honoured among the Romanes; witneſſe *Tarquine* the Proud, the laſt king of
Rome, when his ſonnes Embaſſadours were come unto him for to underſtand his adviſe, how to
B compaſſe the ſiegnorie over the Gabians; drew them into his garden, & there by circumſtance
of topping the heads of the higheſt Poppies there growing, without any anſwere parole, diſpat-
ched them away, ſufficiently furniſhed by this demonſtration, with a bloudie deſſigne, even to
fetch off the greateſt mens heads of the citie, the readieſt meanes to effect his purpoſe.

Againe, there is another ſort of hearbes, that love for companie to be ſet or ſowne together
about the Æquinox in Autumne, namely, Coriander, Dill, Orach, Mallowes, Garden dockes or
Patience, Chervill (which the Greekes call Pæderos) and Senvie, which is of a moſt biting and
ſtinging taſt, of a fierie effect, but natheleſſe very good and wholſome for mans bodie: this hearb
will come of it ſelfe without the hand of man, howbeit, prove it will the better if the plant be re-
moved and ſet elſewhere. And yet, ſow a ground once withall, you ſhall hardly rid the place of it
C cleane: for the ſeed no ſooner ſheddeth upon the ground, but a man ſhall ſee it greene above
ground. It ſerveth alſo to make a pretie diſh of meat to be eaten, being boiled or ſtewed between
too little diſhes in ſome convenient liquor, in ſuch ſort, as a man ſhall not feele it to bite at the
tongues end, nor complaine of any eagerneſſe that it hath. The leaves beſides uſe to be ſodden,
like as other pot-hearbes. Now there bee of this Senvie, three kinds: the firſt beareth ſmall and
ſlender leaves, the ſecond is leaved like Rapes or Turneps, the third reſembleth Rocket. The beſt
Muſtard ſeed commeth out of Ægypt. The Athenians were wont to call it Napy, ſome Thaſpi,
and others Saurion.

To conclude, as touching the running wild Thyme, and Siſymbrum, i. Horſe-mint or Water-
mint, moſt hils are repleniſhed and tapiſſed as it were therewith: and ſpecially in Thracia, where
D a man ſhall ſee a mightie quantitie of wild Thyme braunches, which the mountaine waters or
land flouds carie away and bring it downe with their ſtreame to rivers ſides, and then folke plant
them. Semblably, at Sicyone there groweth great ſtore, conveighed thither from the mountains
neare adjoining: and laſtly, at Athens, brought thither out of the hill Hymettus. In like manner
alſo the foreſaid Water-mint commeth from the hils with a ſuddain daſh of raine, and is replan-
ted accordingly. It groweth rankeſt and proſpereth beſt in the brinkes and ſides of pits or wels,
alſo about fiſh-ponds and ſtanding pooles.

Chap. ix.

Of Finkle or Fenell and Hempe.

E

IT remaineth now among garden hearbes to ſpeake of thoſe that bee of the Ferule kind, and
namely of Fenell in particular, a hearb wherin Snakes and ſuch ſerpents take exceeding great
delight, as heretofore I have declared: and which being dried, is ſingular good to commend
many meats out of the kitchin into the hall.

There is a plant reſembleth it much, named Thapſia, whereof becauſe I have alreadie written
among other forraine hearbes, I will proceed forward to Hempe, which is ſo profitable and good
for to make cordage. This plant muſt bee ſowed of ſeed after the Weſterne wind Favonius blow-
eth in Februarie. The thicker that it groweth, the ſlenderer and finer it is. When the ſeed thereof
is ripe, namely, after the Æquinox in Autumne, folke uſe to rub it out, and then drie it either in
F the Sunne, the wind, or ſmoke. But the ſtalke or ſtem of the Hempe it ſelfe, they plucke out of the
ground after Vintage: and it is the Husbandmans night worke by candle light to pill and cleanſe
it. The beſt Hempe commeth from Alabanda, eſpecially for to make nets and toile; where bee
three kinds thereof. That part of the Hempe which is next to the rind or pilling, as alſo to the
inner pith within, is worſt: the principall of it lieth in the middeſt, and called it is Meſa. Next to
the

the Alabandian Hempe for goodneſſe, is that of Mylaſium. But if you goe to the talneſſe, there is about Roſea in the Sabines countrey, Hempe as high as trees. G

As touching the two kinds of Ferula, I have ſpoken of them in my diſcourſe of forrain plants. The ſeed of Ferula or Fennell-geant, is counted good meat in Italie: for it is put up in pots of earth well ſtopped, and will continue a whole yeare. And of two ſorts is this preſerved Compoſt, to wit, the Stalkes, and the Bunches whiles they be knit round and not broken and ſpread abroad. And as they call theſe knobs which they doe condite and keepe, Corymbi; ſo that Ferula, which is ſuffered to riſe up in ſtem for to beare ſuch heads, they tearme Corymbias.

Chap. x.

The maladies incident to Garden hearbes. The remedies againſt Piſmires, Canker-wormes, and Gnats. H

THe hearbes of the garden be ſubject to diverſe accidents, & namely, diſeaſes; as well as corn and other fruits of the earth. For not onely Baſill by age doth degenerat from the owne nature into wild creeping Thyme, but Siſymbrium alſo into Calaminth. The ſeed of an old Cole-wort will bring forth Turneps: and contrariwiſe, ſow the ſeed of an old Rape and Turnep, you ſhall have Coleworts come up of it. Cumin, if it be not kept neat and trim with much cleanſing, will begin to decay at one ſide of the ſtalke beneath, and die. Now hath Cumin but one onely ſtalke, and a root bulbous in manner of an Onion: it groweth not but in a light and leane ſoile. Otherwiſe, the peculiar diſeaſe appropriat to Cumin, is a kind of ſcurfe or ſcab. Alſo Baſil, I toward the riſing of the Dogge-ſtar, waxeth wan and pale. And generally, there is not an hearbe but will turne yellow, if a woman come neere unto it whiles ſhee hath her monthly ſickneſſe upon her.

Moreover, there be diverſe ſorts of little beaſts or vermine engendred in the garden among the good hearbes. And namely, upon the Navewes, you ſhall have gnats or flies: in Radiſh roots cankerwormes, and other little grubs: likewiſe, in Lectuce and *Beet leaves. And as for theſe Beet worts laſt named, you ſhall ſee them haunted with ſnailes, as well naked as in ſhels. In Leekes moreover or Porret there ſettle other ſpeciall vermine that bee noiſome to them ſeverally, but ſuch are very ſoone taught by throwing upon thoſe hearbes a little dung, for to it will they gather to ſhrowd and hide themſelves. Furthermore, *Sabinus Tyro* in his booke entituled *Cepuricôn, K which he dedicated to *Mecœnas*, writeth, That it is not good to touch with knife or hooke, Rue, Winter Saverie, Mint, and Baſill. The ſame Author alſo hath taught us a remedie againſt Emmets (which do not the leaſt miſcheefe to gardens, when they lie not to have water at command) and that is this, to take ſea mud or ooſe and aſhes together, to temper a morter of them both, and therewith to ſtop their holes. But the moſt forcible and effectuall thing to kill them, is the hearbe called Ruds or Turn-ſol. Some are of opinion, that the onely meanes to chaſe theſe ants away, is, with water wherein the pouder of a ſemi-bricke or halfe-baked tile is mingled. And particularly, for to preſerve Navewes, it is a ſingular medicine for them to have Feni-greeke ſowed among, as alſo for Beets to doe the like with Cich peaſe: for this deviſe will drive away the Cankerworme. But ſay, that this practiſe was forgotten, and that the foreſaid hearbs be alreadie come L up, what remedie then? Marie, even to ſeeth Wormewood and Houſleeke (which the Latins call Sedum, the Greekes Aeizoon) and ſprinckle the decoction or broth therof among them. Now what manner of hearbe this Houſleeke is, I have ſhewed you alreadie. It is a common ſpeech, that if a man take the ſeed of Beets and other pot-hearbes, and wet them in the juice of Houſleeke, otherwiſe called Sea-greene, thoſe hearbes ſhall be ſecured againſt all theſe hurtfull creatures whatſoever. And generally, no Cankerwormes ſhall doe harme to any herbage in the garden, if a man pitch upon the pales about a garden the bones of a Mares head; but he muſt be ſure it was of a Mare, for a horſe head will not ſerve. It is a common ſaying alſo, that if a river Crab or a Craifiſh be hung up in the mids of a garden, it is ſingular for that purpoſe. Some there are who make no more but touch thoſe plants which they would preſerve from the ſaid vermin, only with M twigs of the Dog berie tree, and they hold them wariſhed and ſafe ynough. Gnats keepe a foule ſtir in gardens where water runneth through eſpecially, and wherein there bee ſome ſmall trees growing: but theſe are ſoone chaſed away by burning a little Galbanum.

*Oleri.

*Of Gardening.

Chap.

A

Chap. xi.

What garden seeds be stronger, which be weaker than others. Also, what plants prosper better with salt water.

NOw as touching the change and alteration in seeds, occasioned by age and long keeping: some there be that are firme and fast, which hold their owne well, as namely, the seeds of Coriander, Beets, Leekes, garden Cresses, Senvie or Mustard seed, Rocket, Saverie, and in one word, all such as be hote and bite at the tongues end. Contrariwise, of a weaker nature, are the seeds of Orach, Basill, Gourds, and Cucumbers. Generally, all Summer seeds last longer than
B Winter: and Chibboll seed least of any other will abide age. But take the strongest and hardliest that be, you shall have none good after foure yeares, I meane only for to sow. And yet I must needs say, that Saverie seed will remaine in force and above that time. Raddishes, Beets, Rue, and Saverie, find much good by being watered with salt water; for to these especially it is wholesome Physicke against many infirmities: and besides, it is thought to give them a pleasant and commendable tast, yea, and it causeth them to bee more fruitfull. As for all other hearbes, they find benefite rather by fresh water. And since wee are light upon the mention of waters, those are thought best for this purpose which are coldest and sweetest to be drunke. Standing waters out of some pond, such also as are conveighed into gardens by trenches and gutters, are not good for a garden, because they bring in with them the seeds of many a weed. But above all other, rain wa-
C ters comming in white showers from heaven, be they that nourish a garden best, for these showers kill the vermine also which are breeding therein.

Chap. xii.

The manner of watering Gardens. What hearbes will proove the better by removing and replanting. Of the juices and savours that Garden hearbes afford.

THe best time of the day to water gardens, is morning and evening, to the end that the water should not be overheat with the Sunne. Basill onely would be watered also at noone. And
D moreover, some thinke, that when it is new sowen, it will make hast to come up very speedily, if it be sprinckled at the first with hote water. Generally, all hearbes proove better, and grow to be greater, when they be transplanted, but principally Leekes and Navewes. Nay, this removing and replanting of them is the proper cure of many sorances, for from that time forward, subject they will not be to those injuries that use to infest them; and namely, Chibbols, Porret, or Leekes, Raddish, Perseley, Lectuce, Rapes or Turneps, and Cucumbers. All hearbes which by nature grow wild, lightly have smaller leaves and slenderer stalkes: in tast also they be more biting and eager, than such of that kind as grow in gardens: as wee may see in Saverie, Origan, and Rue. Howbeit, of all others the wild Docke is better than the garden Sorrell, which the Latines call Rumex. This garden Sorrell or soure Docke is the stoutest and hardliest of all that grow: for
E if the seed have once taken in a place, it will by folkes saying continue ever there: neither can it be killed, doe what you will to the earth, especially if it grow neare the water side. If it bee used with meats, unlesse it bee taken with Ptisacum or husked Barley alone, it giveth a more pleasant and commendable tast thereto, and besides, maketh it lighter of digestion. The wild Docke or Sorrell is good in many medicines. But that you may know how diligent and curious men have been to search into the secrets of every thing, I will tell you what I have found contrived in certaine verses of a Poet, namely, That if a man take the round treddles of a Goat, and make in every one of them a little hole, putting therein the seed either of Leekes, Rocket, Lectuce, Persely,
5 Endive, or garden Cresses, and close them up, and so put them into the ground, it is woonderfull how they will prosper, and what faire plants will come thereof. Over and besides, this would bee
F noted, that all hearbes wild, bee drier and more keene than the tame of the same kind. For this place requireth, that I should set down the difference also of their juice & tasts which they yeeld, and rather indeed than of Apples and such like fruits of trees. The tast or smacke of Saverie, Origan, Cresses, and Senvie, is hote and biting. Of Wormewood and Centaurie, bitter. Of Cucumber, Gourds, and Lectuce, waterish. Of Majoram it is sharpe only: but of Persely, Dill, and Fennell,

nell, sharpe, and yet adorant withall. Of all smacks, the salt taste onely is not naturall. And yet otherwhiles a kind of salt settleth like dust, or in manner of roundles or circles of water upon hearbes: howbeit, soone it passeth away, and continueth no longer than many such vanities* and foolish opinions in this world. As for Panax, it tasteth much like Pepper: but Siliquastrum or Indish Pepper more than it, & therfore no marvaile if it were called Piperitis. Libanotis smelleth like Frankincense. Myrrhis, of Myrrhe. As touching Panace, sufficient hath been spoken already. Libanotis commeth naturally of seed in rotten grounds, leane and subject to deawes: it hath a root like to Alisanders, differing little or nothing in smell from Frankincense. The use of it, after it be one yeare old, is most wholesome for the stomack. Some tearme it by another name, Rosemarie. Also Alisanders, named in Greeke Smyrneum, loveth to grow in the same places that Rosemarie doth, and the root resembleth Myrrhe in taste. Indish Pepper likewise delighteth to bee sowed in the same manner. The rest differ from others both in smell and taste, as Dill. Finally, so great is the diversitie and force in things, that not onely one chaungeth the naturall taste of another, but also drowneth it altogether. With Persely the Cookes know how to take away the soureness and bitterness in many meats: with the same also our Vinteners have a cast for to rid wine of the strong smell that is offensive; but they let it hang in certaine bags within the vessels.

* For some Philosophers held opinion, That the taste of hearbes consisted of a Terrene substance and a Waterie mixed together: others (as *Democritus*) ascribed it to their formes and figures: which *Plinie* thinketh ridiculous.

Thus much may serve concerning Garden hearbes, such I meane onely as be used in the kitchin about meats. It remaineth now to speake of the cheefe worke of Nature contained in them: for all this while we have discoursed of their encrease and the gaine that may come thereof: and indeed treated wee have summarily of some plants and in generall tearmes. But for as much as the true vertues and properties of each hearbe cannot throughly and perfectly be knowne, but by their operations in Physicke; I must needs conclude, that therein lieth a mightie peece of worke, to find out that secret and divine power, lying hidden and enclosed within: and such a peece of worke, as I wot not whether there can be found any greater. For mine owne part, good reason I had, not to set downe and annex these medicinable vertues to every hearbe; which were to mingle Agriculture with Physicke, and Physicke with Cookerie, and so to make a mish mash and confusion of all things. For this I wist full well, that some men were desirous onely to know what effects they had in curing maladies, as a studie pertinent to their profession; who no doubt should have lost a great deale of time before they had come to that which they looked for, in running through the discourses of both the other, in case wee had handeled all together. But now, seeing every thing is digested and raunged in their severall rankes, as well pertaining to the fields, as the kitchin, and the Apothecaries shop; an easie matter it will be for them that are willing and so disposed, to sort out each thing and fit himselfe to his owne purpose, yea, and joine them all at his pleasure.

THE XX. BOOKE OF THE HISTORIE OF NATVRE, WRITTEN BY C. PLINIVS SECVNDVS.

The Proëme.

*Since we are come thus farre, as to treat of the greateſt and principall worke of Nature, we will begin from hence forward at the very meats which men put into their mouths, and conveigh into their ſtomackes, and urge them to confeſſe a truth, that hitherto they have not well knowne thoſe ordinarie meanes whereby they live. And let no man in the meane time thinke this to bee a ſimple or ſmall peece of knowledge and learning, going by the baſe title and bare name that it carieth: for ſo hee may be ſoone deceived. For in the purſute and diſcourſe of this argument, wee ſhall take occaſion to enter into a large field as touching the peace and warre in nature; we ſhall handle I ſay a deepe ſecret, even the naturall hatred and enmitie of dumbe deafe and ſenceleſſe creatures. And verely, the maine point of this theame, and which may raviſh us to a greater wonder and admiration of the thing, lieth herein, That this mutuall affection which the Greekes call Sympathie, wherupon the frame of this world dependeth, and whereby the courſe of all things elſe doth ſtand, tendeth to the uſe and benefit of man alone. For to what end elſe is it, that the element of water quencheth fire? For what purpoſe doth the Sunne ſuck and drinke up the water, as it were to coole his heat and allay his thirſt? and the Moone contrariwiſe, breed humors and engender moiſt vapors? and both Planets eclipſe & abridge the light one of the other? But to leave the heaven and thoſe cæleſtiall bodies in their majeſtie; What is the cauſe that as the Magnet or load-ſtone draweth yron unto it, ſo there is another * ſtone abhorreth the ſame and drives yron from it? What ſhould the reaſon bee of the Diamant, that peerleſſe ſtone, the cheefe jewell wherein our rich worldlings repoſe their greateſt joy and delight: a ſtone otherwiſe *invincible, and which no force and violence beſides can conquer, but that it remaineth ſtill infrangible; and yet that the ſimple bloud of a poore Goat is able to burſt it in peeces? Beſides many other ſecrets in Nature, as ſtrange, yea and more miraculous. All which wee purpoſe to reſerve unto their ſeverall places, and will ſpeake of them in order. Meane while may it pleaſe the Reader to pardon us, and to take in good part the manner of our entrance into this matter: for albeit we ſhall deale in the beginning with the ſmalleſt and baſeſt things of all others, yet ſuch they be as are wholſome, and concern much the health of man and the maintenance of his life. And firſt will wee ſet in hand with the Garden, and the Hearbs that we find there.*

* Theamedes, cap. 16. lib. 36.

* Whereupon it is called *Adamas.*

Chap. I.

Of the wild Cucumber and the juice thereof Elaterium.

THis wild Cucumber, as we have ſaid heretofore, is far leſſe than that of the garden. Out of the *fruit hereof there is a medicinable juice drawne, which the Phyſicians call Elaterium. For to get this juice, men muſt not ſtay untill the *Cucumber be fully ripe: for unleſſe it bee taken betimes and cut downe the ſooner, it will leape & flurt in the handling from the ſtele whereto it hangeth, againſt their faces, with no ſmall danger of their eie ſight. Now when it is once gathered, they keep it ſo one whole night. The next morrow they make an inciſion and ſlit it with the edge of a cane. They uſe to ſtrew aſhes alſo thereupon, to reſtraine and keepe down the liquor which

* *Semen pro fructu abuſive.*

* Wherupon it is called *Tomachmenos.*

which issueth forth in such abundance: which done, they presse the said juice forth, and receive G
it in raine water, wherein it setleth: and afterwards, when it is dried in the Sunne, they make it up into Trochisques. And certaine these Trochisques are soveraigne for many purposes, to the great good and benefit of mankind: For first and foremost, it cureth the dimnesse and other defects or imperfections of the eyes: it healeth also the ulcers of the eielids. It is said moreover, that if a man rub never so little of this juice upon vine roots, there will no birds come neare to pecke or once touch the grapes that shall hang thereon.

The root of this wild Cucumber, if it be boiled in vinegre and made into a liniment, and so applied, is singular good for all kinds of gout; but the juice of the said root helpeth the tooth-ach. The root being dried and incorporat with rosin, cureth the ringworme, tettar, and wild scab or skurfe, which some call Psora and Lichenes: it discusseth and healeth the swelling kernels be- H
hind the eare; the angrie pushes also and biles in other Emunctories called Pani: and reduceth the stooles or skars left after any sore, and other skarres, to their fresh and native colour againe. The juice of the leaves dropped with vinegre into the ears, is a remedie for deafenesse. As for the liquor concrete of this Cucumber, named Elaterium, the right season of making it, is in Autumne: neither is there a drug that the Apothecarie hath, which lasteth longer than it doth: howbeit, before it be three yeeres old, it beginneth not to be in force for any purpose that a man shall use it: & yet if one would occupie it fresh & new before that time, he must correct the foresaid Troches with vinegre, dissolving them therin over a soft fire, in a new earthen pot never occupied before: but the elder they be, the better & more effectuall they are; insomuch as (by the report of *Theophrastus*) Elaterium hath been kept and continued good 200 yeers. And for fiftie I
yeeres it is so strong and full of vertue, that it will put out the light of a candle or lampe: for this is the triall and proofe of good Elaterium, if being set near thereto, before that it putteth out the light, it cause the candle to sparkle upward and downward. That which is pale of color, & smooth, is better than that which is of a greenish grasse color & rough in the hand; the same also is somwhat bitter withall. Moreover, it is said, that if a woman desire to have children, & do carie about her the fruit of this wild Cucumber fast tied to her bodie, she shall the sooner conceive & prove with child; provided alwaies, that in the gathering, the said Cucumber touched not the ground in any case. Also, if it be lapped within the woll of a Ram, and bee bound to the loins of a woman in travaile of childbirth, so that she be not her selfe ware thereof, she shall have the better speed and easier deliverance: but then, so soone as the infant and the mother bee parted, the said Cucumber must bee had out of the house in all hast, where the woman lyeth. Those writers who magnifie these wild Cucumbers, and set great store by them, affirme, That the best kind of them groweth in Arabia; and the next about Cyrenæ: but others say, That the principall be in Arcadia; That the plant resembleth Turnsoll; That between the leaves and braunches thereof there groweth the fruit, as big as a Wallnut, with a white taile turning up backeward in manner of a Scorpions taile: whereupon some there bee, who give it the name of the Scorpion Cucumber. True it is indeed, that as wel the fruit it selfe as the juice therof called Elaterium, be most effectuall against the pricke or sting of the Scorpion: as also that it is a medicine purgative of the bellie, but especially cleanseth the wombe or matrice of women. The ordinarie Dose is from halfe an
Obolus, ℈ß. i. halfe a Scriptule or Scruple. Obolus to a Solid [*i.* a dram;] according to the strength of the Patient. A greater receit than L
one Obolus, killeth him or her that taketh it: but beeing taken within that quantitie above named, in some broth or convenient liquor, it is passing good for the dropsie, yea and to evacuate those filthie humors that engender the lowsie disease. Beeing tempered with honie and old oile, and so reduced into a thin ointment or liniment, it cureth the Squinancie, and such diseases incident to the windpipes.

Chap. II.

Of the Serpentine Cucumber, called otherwise the Wandering Cucumber: also of the Garden Cucumbers, Melons or Pompions.

M
MAny there be of opinion, that the Serpentine Cucumber among us, which others call the Wandring Cucumber, is the same that the former Cucumber which yeeldeth Elaterium. The decoction whereof is of that vertue, that whatsoever is besprinkled therewith, no myce will come neare to touch it. The same being sodden in vinegre and brought to the consistence

A conſiſtence of an oïntment, is a preſent remedie to allay the pains of gout, as well in feet, hands, knees and arms, as in any other joynt whatſoever. Alſo, if the ſeed thereof, or the fruit alone, dried in the Sun and beaten to powder, be drunke to the weight of 30 deniers (Romane) in one tremine or wine pint of water, it aſſuageth the paine of the reines and the loines. Tempered with womans milke, it reſolveth all ſodaine tumors and ſwellings, being applied to the grieved place. But to come againe to Elaterium, it mundifieth the matrice and naturall parts of women; but if they be with child, they muſt take heed how they meddle with it, for it bringeth them to a ſhift, yea and haſteneth abortive or untimely birth. Good it is for all them that be ſhort winded. As for the yellow jaundiſe, it cureth it, if it be but ſnuffed up into the noſe. Annoint or bath the face with it in the Sun, it taketh away pimples and other ſpots there. Many attribute all the ſame
B properties and effects to the Garden Cucumbers: And in very deed, this fruit would not be deſpiſed, in regard of the uſe thereof in Phyſicke: for firſt and foremoſt, Take Cucumber ſeeds as many as three fingers will receive, ſtampe them with Cumin, and give the powder in wine to them that have the cough, for to drinke, you ſhall ſee preſent helpe. The ſame ſeeds taken in powder with breaſt-milke, cureth thoſe that bee lunaticke and * phranticke. Alſo, the weight of one * Acetabulum, [*i.* much about two ounces] cureth them that have the Dyſenterie or bloudie flix. Moreover, being taken with a like poiſe or quantitie of Cumin ſeed in mead or honyed water, it is ſingular good for them that reach up filthie matter from their lungs; as alſo for thoſe who have * weake and diſeaſed livers. If one drinke the ſame with ſome ſweet wine, it provoketh urine: and being injected by a clyſtre togither with Cumin, it eaſeth the paine in the kidnies
C and reines.

* *Phreniticis*, ſome read *Nephriticis*, and then it ſignifieth thoſe that have the ſtone or pains of the kidnies.
* 15 drams.
* *Iocineroſi.*

As for the fruit called Pompions or Melons, being eaten as meat, they coole the bodie mightily and make it ſoluble. The fleſhie ſubſtance of them applied unto the eyes, aſſuageth their pain and reſtraineth their wateriſh and rheumaticke flux. Their root healeth the * wens or ulcers gathered in manner of honey-combs: which ſwellings ſome call Ceria. Being dried, it ſtaieth vomits, ſo it be brought into powder and given to the weighr of * foure Oboli in honyed water: but the Patient when he hath drunke it, muſt walke preſently upon it halfe a mile. The ſame powder is deterſive and ſcouring, and therfore put into ſope and waſhing-balls. As for the rind or barke thereof, it procureth vomit indeed, but it cleanſeth the skin as well as the other. The ſame doe the leaves of any domeſticall or garden Cucumbers or Melons, if they be made into a lini-
D ment. The ſaid leaves alſo ſtamped with honey and brought to the forme of a cataplaſme, cure the bloudie-falls or night-blains: but tempered with wine, they heale the bitings of dogs, as alſo of the Millepeed, which the Greeks call Seps, a long worm with hairie feet, doing much harme to cattaile eſpecially; for looke where it biteth, the place preſently ſwelleth and putrifieth. The very Cucumber it ſelfe is of a comfortable odour, and recovereth the faintings of the heart, and thoſe that ſwoune. Finally, if you would make a delicat ſalad of Cucumbers, boile them firſt, then pill from them their rind, ſerve them up with oile, vinegre, and honey: certein it is, they are by this means far ſweeter and plenſanter than otherwiſe.

* *Meliceridas.*

* two ſcruples.

Chap. iii.

E

Of the wild Gourd, and the Rape or Turnep.

THere is a kind of wild * Gourd, which the Greeks call Somphos, as one would ſay, hollow and emptie, (for thereupon it tooke that name) a finger thicke, growing no where els but among rocks and ſtonie grounds. If a man chew this Gourd and ſucke out the juice therof, he ſhall find it very comfortable to the ſtomacke. There is another wild Gourd called Colocynthis, but that is full within, and leſſe than that of the Garden. The pale of this kind is the better, for ſuch be uſed in Phyſicke: and yet that of graſſe greene colour when it is dried, if it bee taken alone, doth purge and evacuat the belly. Alſo being infuſed into the bodie by way of clyſtre, it cureth all the diſeaſes of the guts, flanks, reins, and loins: it helpeth the palſie likewiſe, or the re-
F ſolution of the ſinews. After the ſeeds be taken forth, ſome fill the place with honyed water, and ſo ſeeth all togither untill halfe be conſumed, and give of this decoction the quantitie of foure Oboli, with good ſucceſſe to thoſe that be troubled with a cough. The powder therof dried & incorporat with ſodden honie, & ſo reduced into pills and ſwallowed, is good for the ſtomack. The ſeeds be ſingular to cure the Iauniſe; but the partie muſt drinke honyed water preſently after it.

* This is not *Colocynthida.*

The fleshie pulpe within mixed with wormwood and honey, taketh away the tooth-ach: & a col- G
lution made with the juice thereof and vinegre hot, confirmeth and fasteneth the teeth that be
loose in the head. Moreover, if with it and oile togither, one rub the backe-bone, the loins, and
the haunches or huckle, it will immediatly rid them of their paine and ach. But I will tell you a
straunge and wonderfull effect indeed: If a man take their seeds of * even number, & hang them
either about the necke or armes of them that have the ague, they will drive the acceſſe or fit
away; be it any of those intermittent fevers which the Greeks call Periodicall. Thus much for
the wild Gourd, Colocynthis.

* It may be, he meaneth a number respective to the type of the ague, that is to say, 3 in a tertian, 4 in a quartan, 5 in a quintan, &c.

As for the domesticall Gourd of the Garden, after it is scraped and pilled, take the juice
thereof and distill it warme into the eares, it will ease the paine. The inner flesh or pulpe clean-
sed from the seed, is passing good for to be applyed to the agnels or corns of the feet: also to be H
laid unto those impostumes or swellings, that grow to an head or suppuration [which the
Greeks call Apostemata.] The liquor or decoction of the Gourd, sodden all whole as it is, with
rind, seed, and pulpe, doth strengthen the loose teeth, and stinteth their ach. Wine wherein it is
boiled, is a singular decoction to bath the eyes, for to represse and stay the flux or rheume that
falleth upon them. The leaves of it, togither with the fresh leaves of the Cypresse tree newly
gathered, being stamped and applied to wounds, be excellent to heale them. The Gourd it selfe
enclosed within clay, and so baked or rosted under the embers, and then stamped and incorpo-
rate with goose grease, hath the like effect. Moreover, the scrapings or shavings of the rind,
mightily cooleth the heat of the gout, if it be not inveterate and old: the heats also of the head,
* Seriasis. and especially the * burning therein, which troubleth little infants. The said parings being in- I
corporat with the filth rubbed or curried from mens bodies in bains and stouves after they have
swet, and so laid upon any part that hath S. *Anthonies* fire, allaieth the heat and bringeth the
place into temper: so doe the seeds also, used in the like manner. The juice or liquor drawn out of
the said parings, being mingled with oile of roses and vinegre, and then made into a liniment,
doth mitigate the extreame heat of burning fevers. The ashes of Gourd parings burnt and stre-
wed drie upon any part of the bodie that is burnt or skalded, doth heale them wonderfully. *Chry-
sippus* the Physician condemned Gourds, and forbad men to eat of them. Howbeit, all Physici-
ans doe resolutely agree in this, That they be passing good for the stomacke: as also for the ex-
ulcerations of the guts and bladder.

As for Rapes or Turneps, they likewise are medicinable and have their use in Physicke: for to K
begin withall, if one lay them very hot to kibed or humbled heeles, they will cure them. Also, if
the feet be frozen and behummed with cold, lay them therto sodden in water, and this fomenta-
tion will restore them to their former heat. The hot decoction or broth of Rapes, is passing good
for to bath the goutie members, yea if it were a cold gout. The Rape or Turnep root, raw as it
grew, brayed in a mortar with salt, is a remedie for all diseases of the feet, be they cornes, kibes,
bloudy fals, swellings of cold, or any other infirmities whatsoever. Rape seed bruised to a lini-
ment drunken also with wine, is reported to be a soveraigne medicine against the stinging of ser-
pents, and any other poison: Howbeit many thinke, that it is a preservative and countrepoison,
when it is taken in wine and oile. *Democritus* banished Turneps altogither from the bourd, by
reason of the ventosities or windinesse that it engendreth. But *Diocles* on the other side extolled L
and praised them as much; and affirmeth, That they will pricke forward to *Venus*. The like doth
Dionysius report of them, and the rather (saith hee) if they be condite with Rocket. Hee writeth
moreover, That if they be rosted or baked under the ashes, and so incorporat with grease, they
will make a notable good cataplasme for the gout & joynt-ach. The wild Rape or Turnep grow-
eth commonly every where among corne fields: it braunceth much, carrieth a white seed, twise
as big as that of the Poppie. This being incorporat with urine of equall quantitie, is much used
to take away rivels, and to smooth the skin both of the face and also of the whole bodie besides.
To conclude, the roots of Ervile, Barley, Wheat, and Lupins, be good for nothing at all.

Chap. iiii.

M

The divers sorts of Navews: of the wild Radish: of the Garden Radish, and the Parsnep.

* *Angulosis caulibus, folio apij, flore anethi.* Ex Dioscoride.

THe Greeke writers observe two kinds of Navews, which serve for Physicke. The first riseth
up with *a cornered and edged stalke, beareth leaves resembling Parsley, and putteth out

floures

A floures like Dill: this they call Bunion: the decoction whereof beeing drunken with honyed water, or with a dram weight of the owne juice, is counted soveraigne for the purgations that follow women, for the defects of the bladder and urine. The seed parched and beaten to powder, and so taken in a draught of hot water, to the quantitie of foure * cyathes, cureth the bloudie flix: but it stoppeth urine unlesse the Patient drinke Line-seed withall. The second kind is named Bunias, and resembleth both Rape and Radish: the seed of it is excellent good against poison, and therefore in Antidotes or preservatives it is much used. That there be Radishes wild, we have shewed heretofore. The most commended above all others, is that which groweth in Arcadia: although there are of them in other countries, and those counted better, onely for to provoke urine. Otherwise they purge choller, and namely their rinds infused in wine do the same.

* a Cyath is ten drams.

B Now over and besides their vertues and properties related heretofore, they discharge and cleanse the stomacke, cut and extenuate fleame, and withall, be diuretical and procure urine.

There is a kind of Garden Radish in Italy, which they name Armoracia, used also in Physick: the decoction wherof, if a man take a draught of it in a morning, to the quantitie of a cyath, doth fret, breake, and expell the stone by way of gravell. Boile the same in water and vinegre, therwith bath or annoint the place stung with any serpent, and it will heale it up. Radish taken with hony in a morning next ones heart fasting, is good for the cough. The seed parched, and so chewed alone without any thing els, assuageth the pain of the small guts, * in the flanks and Hypochondriall parts. The decoction of Radish leaves sodden in water and so drunke, or the very juice of the root it selfe as much as two cyathes, is thought to be a singular medicine against the breeding

Leganoponon.

C of bodie-lice. Radishes stamped in a mortar and brought into the forme of a liniment, are thought to be excellent good for hot inflammations: the rind also stamped togither with honey and laid to any bruised place that looketh blacke and blew after a fresh stripe, dissolveth that cluttered bloud, and reduceth the former colour. The chewing of the quickest and most biting Radishes, keepeth them awake that are given to overmuch drowsinesse & enclined to the lethargie. The seed parched and afterwards stamped and incorporat with honey, cureth them that take their wind short. The same is also held for a countrepoison. A defensative also the Radish is, against Scorpions, and resisteth their poisoned sting: for let a man rub his hands well either with the juice of the root, or the seeds, he may handle Scorpions safely. Doe but lay a Radish upon a Scorpion, he will presently die. Moreover, *Nicander* affirmeth, That Radishes be passing good

D for them that have eaten either venomous mushroms, or els Henbane. The two *Apollodores* prescribe Radish to be given unto them, who suspect themselves to be poisoned with the viscous gum of the white Chamæleon root called Ixias; but taken diversly: for the one of them surnamed *Citieus*, giveth the seed stamped, and so to drinke it in water: the other *Apollodorus*, of Tarrentum, ordaineth the juice of Radish for this effect & purpose. Moreover, Radishes are thought good to diminish and extenuat the swelling splene: they are holesome for the liver, and mitigate the paine of the loines. Being taken with vinegre or Senvie, they help them that are in a dropsie, or falne into a lethargie. *Praxagoras* is of judgement, That Radishes should be given for to eat, unto them that are troubled with the Iliacke passion, to wit, the paine and wringing of the small guts. And *Plistonicus* appointeth them to be eaten of those that bee troubled with a continuall

* *Iliosis, Hermol.* some read *Ileosis*, & then it signifieth, Purflixe.

E flux, by reason of a feeble stomacke, called thereupon Cœliaci. They heale the Dysenterie or exulceration of the guts: they evacuat also and rid away the filthie matter and corruption of impostumes gathered about the midriffe and principall parts, if they be eaten with honey. But some for this purpose would have them luted or bedawbed with clay, and so rost or bake them afterwards under the ashes; and being thus prepared, they are effectuall to bring downe womens tearms. Being taken with vinegre and honey in manner of an oxymel, they chase wormes out of the guts and belly. If they be sodden to the thirds, and their decoction given to drink with wine, they doe much good to them who have a rupture, and their guts falne downe into the burse of

F their cods: and in this wise they rid and skoure away the cluttered and offensive bloud gathered in the guts, and sent thither from any other part. *Medius* the Physician prescribeth them to bee boiled and given to the same purpose; as also to those that spit and reach up bloud: yea and to women in childbed newly laid, for to encrease their milke. *Hippocrates* counselleth women whose haire is given to shed much, for to rub their heads with Radish roots: also to apply them bruised in manner of a cataplasme unto the navell, when they be tormented with the paines of the matrice. They will bring to the native and lively colour, the parts that are cicatrized or newly skarred.

red. The ſeed bruiſed and tempered with water, and ſo laid as a cataplaſme, ſtayeth the running of cancerous or eating ulcers, which the Greekes call Phagedænæ. *Democritus* is of opinion, That much feeding upon Radiſhes, ſtirreth up luſt and maketh folke amorous; which peradventure is the reaſon, that ſome have thought they be hurtfull to the voice. The leaves of thoſe Radiſhes onely that have the longer roots, are ſaid to quicken the eye-ſight: but if a man perceive that hee hath either inwardly taken for a medicine, or applied outwardly, a Radiſh root which is over ſtrong, he muſt preſently have Hyſſope given him: for this Antipathie and naturall contrarietie there is betweene theſe two hearbs, That the one correcteth the other. For them that bee hard of hearing, Phyſicians uſe to inſtill the juice of the Radiſh by drop-meale into the eares. And for them that would perbreake or vomit, the beſt way to take it, is at the end of a meale with the laſt meat. G

* *Summo cibo*, although *Dioſcorides* ſaith *primo cibo*: and himſelfe in the former booke *Jeiunii*,

As touching Hibiſcum, like it is to the Parſnep: ſome call it Moloche Agria, others Piſtolochia: it cureth the ſores and ulcers that bee in griſtles, and knitteth broken bones. The leaves thereof drunke with water, looſen the belly, and chaſe away Serpents. Applied in a liniment or otherwiſe rubbed upon a place ſtung with Bee, Waſpe, or Hornet, they are a preſent remedie. The roots thereof digged out of the ground before Sun-riſing, and enfolded or wrapped in wooll as it grew upon the ſheeps backe, without any other artificiall colour, and namely of an ewe, which hath yeaned likewiſe an ewe lambe; is thought to be a ſingular thing for to be bound unto the ſwelling kernels called the Kings evill, yea although they were exulcerat and ran. But ſome are of this mind, That for to doe this deed, it ſhould bee gotten up with an inſtrument of gold; and great heed ſhould be taken, that after it is once up, it touch not the earth againe. Finally, *Celſus* giveth counſell, to lay the root thereof ſodden in wine to the goutie joynts that are without tumor and ſhew no ſwelling. H I

Chap. V.

Of Staphylinus, or the Parſnep. Of Chervill, the Skirwirt: of Seſeli, Elecampane, and Onions.

There is a ſecond kind of Parſnep, named Staphylinus, which commonly men call the Wandring parſnep. The ſeed bruiſed and drunke in wine, is ſingular good for them that have ſwolne bellies; the riſing or ſuffocation of the mother in women, with the torments and paines thereto incident, it cureth; inſomuch as it reduceth the matrice into the right place: being applied alſo as a liniment with wine cuit, it helpeth the wrings and throwes of their belly. It is not amiſſe alſo for men to take it; for the ſeed being ſtamped togither with bread crums, of each a like portion, and ſo drunke with wine, cureth the belly-ach with them alſo. It provoketh urine: and beeing applied freſh and new with honey, it repreſſeth the ſpreading of fretting and running ulcers. The powder thereof alſo being drie and ſtrewed thereupon, hath the like effect. *Dieuches* adviſeth to give the root therof in honeyed water, againſt the infirmities of liver, ſplene, flankes, ſmall guts, loines, and reines. *Cleophantus* ſaith, that it will helpe (in that manner taken) an old bloudie flix, which hath continued a long time. *Philiſtio* boileth the root in milke, and giveth foure ounces therof to them who are troubled with the ſtrangurie, or piſſe by drop-meale: but with water, he giveth it for the dropſie; to thoſe alſo that with a cricke or crampe have their necks drawne backward; for the pleuriſie, and epilepſie or falling ſickneſſe. Moreover, it is commonly ſaid, That whoſoever hath this root about them, are ſafe enough for being ſtung with any Serpent: nay if they doe but taſt thereof before-hand, they ſhall take no harme if they be either bitten or ſtung by them: and ſay they be alreadie ſtung, let them apply it to the wounded place with hogs greaſe, and it will heale it up. The leaves chewed helpe the indigeſtion and cruditie of the ſtomacke. *Orpheus* ſaid moreover, That this root had an amatorious propertie to win love: haply becauſe much feeding thereof (as it is well knowne) doth ſollicit unto the game of love, and maketh folke amorous: which is the reaſon alſo that ſome have put downe in writing, That it will helpe women to conceive. As for the Garden Parſneps, they are in many other reſpects of great force and very powerfull; but the wild is more effectuall, and principally that which groweth in ſtonie grounds. The ſeed of the Garden Parſnep alſo, being drunke in wine, or vinegre and wine togither, ſaveth thoſe that are ſtung with Scorpions. If a man picke his teeth and rub them all about with a Parſnep root, he ſhall be eaſed of his tooth-ach. K L M

The

A The Syrians are great Gardiners, they take exceeding paines and bee moſt curious in gardening; whereupon aroſe the proverb in Greeke, to this effect, *Many Woorts and Pot-hearbs in Syria.* They uſe to plant in their gardens a certain hearb very like to a Parſnep, which ſome call Gingidium, *i.* Tooth-picke Chervill: more ſlender and ſmaller it is onely, and therewith bitterer in taſt, but it it worketh the like effects. They uſe to eat it both ſodden and raw, & find it agree well with the ſtomacke; for it drieth up all the ſuperfluous humours and excrements which be bedded and deeply rooted within it.

As for the wild Skirwort that groweth wandring every where, it is like both in ſhape and operation to thoſe of the Garden. It ſtirreth up the appetite and skoureth the ſtomack of thoſe crudities which cauſed dulneſſe therein, and loathing to meat. *Opion* is verely perſuaded, that if one
B eat it with vinegre aromatized with Laſerpitium, or take it with pepper and honyed wine, or els with the pickle of fiſh named Garum, it provoketh urine, and putteth him or her in mind of love delights. Of the ſame opinion alſo is *Diocles.* Furthermore, that it is a cordiall, and doth mightily corroborat and ſtrengthen the heart, upon recoverie of a long and daungerous ſickneſſe; and is beſides ſingular good to ſtay the ſtomacke after much caſting and vomiting. *Heraclides* was woont to give Skirworts to them who had drunk Quick-ſilver: to ſuch alſo as were but cold, and could not ſufficiently perform the duties of mariage: finally, to them that being newly crept out of their beds after ſome grievous diſeaſe, had need of reſtoratives. *Hiceſius* was of this mind and ſaid, they were good for the ſtomack becauſe no man could poſſibly eat three Skirwort roots together: and yet he thinketh that they would agree very well with thoſe weake perſons who were
C lately ſick and newly walking abroad, againſt they ſhould fall to their old drinking of wine again. But to come more particularly to the garden Skirwort, If the juice thereof be drunke with Goats milke, it ſtayeth the flux of the belly called the Laske. And thus much for the Skirwort, named in Latin Siſer. But foraſmuch as the proximitie and likeneſſe in many Greeke names many a time confoundeth the memorie and deceiveth men, cauſing them to miſtake one thing for another, I will for vicinitie & neighbourhood ſake annex unto Siſer, the herb Siler or Seſeli; for me thinks they will do very well to ſtand togither: but this is an herb very common & well known. The beſt is that which commeth from Marſeils, & is thereupon named Seſeli Maſſilienſe: it hath a broad flat ſeed and a yellow. A ſecond kind thereof is named Æthiopicum, with a blacker ſeed: but the third which is brought from Candie, and therefore tearmed Creticum, is of all other moſt odo-
D riferous and ſmelleth ſweeteſt. The root of Seſeli or Siler, caſteth a pleaſant ſavour: and as men ſay, the Vultures alſo or Geirs feed upon the ſeed. If a man or woman drinke it with white wine, it cureth an old cough; it knitteth thoſe who are burſen bellied, or have ruptures; and laſtly, helpeth them that bee much troubled with cramps or convulſions. Likewiſe, if it bee taken to the weight or quantitie of two or three * Ligules, it cureth thoſe who have their necks drawne backward to their ſhoulders with the Spaſme; it correcteth the defects & faults of the liver; it allaieth the wrings and torments of the guts; and bringeth them to piſſe with eaſe and freely who are afflicted with the Strangurie. The very leaves of Siler are likewiſe medicinable, for they procure eaſie childbirth: yea and in that reſpect the very dumb four-footed beaſt findeth the benefit therof: and that know the Hinds well enough by a ſecret inſtinct of nature, who beeing neare their time
E and readie to calve, feed upon this hearb moſt of all others. Good it is againſt S. *Anthonies* fire, applied to the place in manner of a liniment. Certes, if a man eat either the leafe or the ſeed of Siler, preſently after meat, or at the latter end of repaſt, it helpeth digeſtion. It ſtaieth the gurrie or running out of the belly in foure-footed beaſts, whether it bee given ſtamped by way of a drench and ſo injected, or chewed drie among their meat with ſalt. If kine or oxen be ſicke, ſtampe it and poure it down their throats, or els clyſterize them with it. As for Elecampane, if it be chewed upon an emptie ſtomacke faſting, it confirmeth the looſe teeth, ſo that it bee taken as it was digged forth of the earth before it touch the ground againe. Beeing confected or condite, it cureth the cough. The juice of the root ſodden, expelleth the broad worms bred in the guts. The powder of it dried in the ſhadow, helpeth the cough, the ſtitch, and cramp, diſſolveth windineſſe; & is good
F for the * accidents incident to the throat and windpipes. It is a ſoveraigne medecine againſt the pricks or ſtings of venomous beaſts. The leaves applied as a liniment, with wine, appeaſe the extreme pain of the loins. As for Onions, I cannot find that there bee any of them grow wild. Thoſe which are ſown in gardens, I am ſure, will with their ſmell only cauſe the eyes to ſhed tears, and by that means clarifie the ſight: but if they be annointed with the juice, they will mundifie the better.

* *Ligula* may be taken for *Cochleare, i.* a ſpoonfull: it containeth three drams and a ſcruple, ſomewhat under halfe an ounce, as a good ſpoone wil do with us.

* *Arterijs.*

It is ſaid that they will procure ſleepe, and heale the cankers or vlcers of the mouth, being chewed with bread. Alſo, greene Onions applied with vinegre to the place bitten with a [mad] dog, or els drie, and laid to with Honie and Wine, ſo that the plaiſter or cataplaſme be not removed, in three daies cureth the hurt without daunger. In this manner alſo they will heale *galled places. Being roſted under the aſhes, many uſe to applie them with Barley floure or meale, as a pulteſſe or cataplaſme to the eies that bee waterie or rheumaticke, as alſo to the vlcers of the privie parts. The imunction of the eies, with the juice thereof, is thought to cleanſe their cicatrices or *cloudineſſe of the eies called the pin & web: as alſo to cure the pearle there breeding: moreover the bloudſhotting or red ſtreakes in the white, & the white ſpots appearing in the blacke circle about the apple. Moreover, it cureth bitings & ſtings of Serpents, yea, and healeth all vlcers, being emplaiſtered with honey. Alſo the exulcerations or impoſtumes within the eares, are by it & womens milke cured. And for to amend the ringing & unkind ſound and noiſe therin, & to recover thoſe that be hard of hearing, many have uſed to drop the juice of Onions together with Gooſe greaſe or els honey. Furthermore, they give it to be drunken with water, unto thoſe that ſuddainly become ſpeechleſſe and dumbe. A collution alſo made with Onions, helpeth the tooth-ach. And being laid upon the wounds, made either with prick or bite of any venomous beaſt, and eſpecially of Scorpions, it is thought to be a ſoveraigne ſalve. Many are wont (to very good effect) for to bruſe Onions, and therewith to rub thoſe parts that be troubled with a skurfe & running mange, as alſo to recover haire where it is ſhed and gone. Being boiled, they are given for to bee eaten, unto thoſe who are diſeaſed with the bloudie Flix or paine of the reines and loins. Their outward pillings burnt into aſhes and mingled with vinegre, cure the bitings and ſtings of ſerpents, if the place bee bathed or annointed therewith, yea, and the very Onion it ſelfe being applied with vinegre, cureth the ſting of that ſhrewd worme Milliped. As for all other vertues and properties of Onions, the Phyſicians are wonderfull contrary one to another in their writings: for our moderne and late writers doe hold and ſo have delivered in their books, That Onions are hurtfull to the parts about the heart, and other vitall members: as alſo, that they hinder digeſtion, breeding wind and ventoſities, and cauſing drought or thirſtineſſe. *Aſclepiades* and his ſect or followers, contrariwiſe affirme, That Onions are ſo wholeſome, that they will make them well coloured who uſe to feed upon them. And more than ſo, they ſay that if one in health every day eat of them faſting, he ſhall be ſure to continue healthfull, ſtrong and luſtie: that they be good for the ſtomack, in this regard, that they cauſe rifting and breaking of wind upward, which is a good exerciſe of the ſtomacke: and withall, that they keepe the bodie looſe and laxative, yea, and open the Hæmorrhoid veines, if they be put up in manner of ſuppoſitories. Alſo, that the juice of Onions and Fennell together, be marvellous good to bee taken in the beginning of a *Dropſie. *Item*, That their juice being incorporate with Rue and Honie, is ſoveraigne for the Squinance. As alſo that they will keepe waking thoſe who are fallen into a Lethargie. To conclude, *Varro* ſaith, That if Onions bee braied with ſalt and vinegre, and then dried, no woormes or vermine will come neare that compoſition.

* Sic & attrita ſanant.

* ὑφέλκια.

* *Hydrópes*, ſome read *Hypochyſes*, i. *Suffuſiones*; out of *Dioſcorides*, to wit, the Cataract.

Chap. vi.

Of cut Leekes or Porret: of bolled Leekes: and of Garlicke.

POrret, otherwiſe called Cut-Leekes or unſet Leekes, ſtancheth bleeding at the noſe, in caſe it be ſtamped and put up cloſe into the noſethrils, or otherwiſe mingled with the pouder of the Gall-nut, or Mints. Moreover, Porret ſtaieth the immoderat ſhift or flux of bloud, that followeth women upon a ſlip or abortive birth, if the juice thereof be drunke in breaſt-milke. In the ſame manner it helpeth an old cough and all other diſeaſes of breaſt and lungs. Burnes and ſcaldings are healed with a liniment made of Porret or Leeke blades: likewiſe the Epinyctides: for ſo in this place I tearme that vlcer, which in the Lachrymall or corner of the eie runneth and watereth continually: ſome call it Syce, that is to ſay, a Fig. And yet others there bee who underſtand by that word [Epinyctides] the blackiſh or blew bliſtering wheales, the bloudie fals I mean and angrie chilblanes, that in the night diſquiet and trouble folke which have them. But to come againe to our Porret: the blades thereof ſtamped and laid too, with Honie, healeth all ſores and vlcers whatſoever. The biting of any venomous beaſt, the ſting alſo of Serpents, are cured therewith. As for the impediments of the hearing and the eares, they be remedied with the juice

of

A of Leekes and Goats gall, or elſe a like quantitie of honied wine inſtilled thereinto. And as for the whiſtlings or craſhing noiſes that a man ſhall heare within head other whiles, they are diſcuſſed with the juice of Leekes and womans milke dropped into the eares. If the ſame be ſnuffled up into the noſthrils, or otherwiſe conveighed that way up into the head, it eaſeth head ach. For which purpoſe alſo it is good to poure into the ear, when one goeth to bed and lieth for to ſleep, two ſpoonefuls of the ſaid juice, and one of Honie. The juice of Porret if it bee given to drinke with good wine of the grape; againſt the ſting of Serpents, and namely, Scorpions: likewiſe ſo taken with an *Hemine of wine, it cureth the paines of the loines or ſmall of the backe. Such as ſpit or reach up bloud, ſuch as be diſeaſed with the Phthiſick or Conſumption of the lungs, ſuch alſo as have been long troubled with the Poſe, the Murre, Catarge, & other Rheumes, find great
B helpe by drinking the juice of Porret, or eating Leekes with their meat. Moreover, Leeks are taken to bee very good either for the Iauniſe or Dropſie. Drinke the ſame with the decoction of husked Barley called Ptiſane, to the quantitie of one Acetable, you ſhall find eaſe for the paines of the raines or kidneies. The ſame meaſure and quantitie beeing taken with Honie, mundifieth the Matrice and naturall parts of women. Men uſe to eat of Porrets or Leekes, when they doubt themſelves to have taken venomous Muſhromes. And a cataplaſm therof cureth green wounds. Porret is a ſollicitour to wantonneſſe and carnall pleaſures: it allaieth thirſtineſſe, & diſpatcheth thoſe fumes that cauſe drunkenneſſe. But it is thought to breed dimneſſe in the eie-ſight: to engender wind and ventoſitie; howbeit, not offenſive to the ſtomacke, for that withall it maketh the bellie laxative. Finally, it ſcoureth the pipes & cleareth the voice. Thus much of Porret in blade,
C or cut Leekes unſet.

The headed Leekes that are bolled and replanted, are of the ſame operation, but more effectuall than the unſet Leekes. The juice thereof given with the pouder either of Gall-nuts, or *Frankincenſe, or els Acacia, cureth thoſe that reject or reach up bloud. *Hippocrates* would have the ſimple juice thereof given, without any thing els for that purpoſe: and he is of opinion, that it will diſopilate the necke of the Matrice and the naturall parts of women; yea, and that they will prove fruitfull and beare children the better, if they uſe to eat Leekes. Being ſtamped and laid to filthie ſores or uncleane ulcers with Honie, it cleanſeth them. Being taken in a broth, made of Ptiſane or husked Barley, it cureth the Cough, ſtaieth the Rheume or Catarrh, that deſtilleth into the chiſt or breaſt-parts: it ſcoureth the lungs and wind-pipe, and healeth their exulcerations
D The like it doth if it be taken raw without bread, three bols or heads of them together ech other day: and in this manner it will cure the patient, although he raught up and ſpit out putrified and corrupt matter. After the ſame manner it cleareth the voice, & it enableth folke to the ſervice of ladie *Venus*, and availeth much to procure ſleepe. If Leeke bols or heads bee ſodden in two waters, that is to ſay, chaunging the water twice, and ſo eaten, they will ſtop the Laske, and ſtay all inveterate Fluxes whatſoever. The pillings or skins of Leeke heads if they bee ſodden, the decoction thereof will chaunge the haire from gray to blacke, if they be waſhed or bathed therewith.

As touching Garlicke, it is ſingular good and of great force for thoſe that chaunge aire, and come to ſtrange waters. The very ſent thereof chaceth Serpents and Scorpions away. And as ſome have reported in their writings, it healeth all bitings and ſtings of venomous beaſts, either
E eaten as meat, taken in drinke, or annointed as a liniment: but principally it hath a ſpeciall propertie againſt the Serpents called Hæmorthoids, namely, if it be firſt eaten, and then caſt up againe by vomit, with wine. Alſo, it is ſoveraine againſt the poyſonous biting of the Mouſe called a Shrew: and no marvell, for why, it is of power to dull and kill the force of the venomous hearb Aconitum, *i.* Libard bane, which by another name men call Pardalianches, becauſe it ſtrangleth or choketh Leopards: yea, it conquereth the ſoporiferous & deadly qualitie of Henbane. The bitings alſo of a mad dog it healeth, if it bee applied upon the hurt or wounded place with him. As for the ſting of Serpents verely, Garlick is exceeding effectuall, if it be taken in drink: but withall, you muſt not forget to make a liniment of it, the hairie ſtrings or beard growing to the head, the skins alſo or tailes and all, wherby it is bunched, tempered all together with Oile, & laid upon
F the greeved place: and thus alſo will it helpe any part of the bodie fretted or galled, yea, though it were riſen up to bliſters. *Hippocrates* moreover was of this opinion, That a ſuffumigation made therewith, fetcheth downe the after-birth of women newly delivered and brought to bed: who uſed alſo with the aſhes of them burnt and reduced together with oile into the forme of a liniment, to annoint the running skalls of the head, and thereby cured and healed them up. Some

give

*Hemina is much about ten ounces.

* Called *Manna Thuris*.

In fico duplici.

give it boiled, others raw, unto them that bee ſhort winded. *Diocles* preſcribeth it with Centaurie G
to them who are in a Dropſie, he giveth it alſo to purge the bellie between, or in two Figges. But
greene Garlicke taken in good wine, together with Coriander, doth the deed more effectually.
Some are wont to miniſter it to thoſe that draw their wind ſhort, being ſtamped & put into milke.
Praxagoras the Phyſician ordained to drinke it with wine, againſt the launiſe: alſo againſt the Iliacke paſſion, in oile and thicke*gruell. And in that ſort hee uſed to annoint the ſwelling kernils,
called the kings evill. In old time the manner was to give raw Garlicke to ſuch as were beſtraught
or out of their wits. But *Diocles* appointed, that it ſhould bee boiled for phranticke perſons.
Certes, if it be bruſed and ſo laid to the throat, or otherwiſe gargled with ſome convenient li-
quour, it will doe much good to them that have the Squinancie. Take three heads or cloves of
Garlicke, beat them well, and together with vinegre applie them to the teeth; they will mightily H
aſſuage the paine. Or doe but make a collution with the broth wherein they were boiled, and hold
it in your mouth, and afterwards put ſome of the Garlicke it ſelfe within the hollow teeth, you
ſhall ſee much eaſe enſue thereupon. The juice of Garlick, together with Gooſe greaſe, is paſſing
good to be dropped into the eares, to aſſuage their paine, and bring the hearing againe. Beeing
taken in drinke, it cleanſeth the head from dandruffe, and killeth lice: ſo doth it alſo, if it be ſtam-
ped and applied to the place with vinegre and nitre. Seeth it in milke, or do but ſtamp it and min-
gle it with ſoft freſh cheeſe, and ſo eat it, you ſhall ſee how it will repreſſe and ſtay Catarrhs and
Rheumes: after which manner it will make them ſpeake cleare that be hoarſe, and have a ruſtie
voice. But let a man who hath the Phthiſick, and is far gone into a Conſumption of the Lungs,
drinke it in Beane broth ordinarily, he ſhall recover or find great eaſe. Generally, Garlick is bet- I
ter, boiled or roſted, than raw: and yet of the twaine, it is not ſo good roſted as ſodden: for in that
order muſt it be taken for to helpe the voice and make a cleare breaſt. Alſo, being boiled in ho-
nied vinegre or Oxymell, and ſo drunke, it driveth out the broad wormes and all other ſuch like
vermine forth of the guts. Beeing taken in a thicke broth or gruell, it cureth the diſeaſe *Tineſ-
mus. Being ſodden to the conſiſtence of an Vnguent, and ſo applied as a frontale to the temples
of the head, it allaieth their paine. Boiled with honie, then ſtamped and reduced to a liniment, it
repreſſeth red pimples. Seeth it with good old ſeame or greaſe, or in milke, it is ſingular for the
Cough. See you one to reach up bloud, or to ſpit filthie matter? Roſt Garlicke under the hote em-
bers, and give it the partie to eat, with equall quantitie of honie. Being taken with ſalt and oile, it
is a ſoveraigne remedie for them that bee burſten or Spaſmaticke, that is to ſay, vexed with the K
Crampe. Applied with the fat or greaſe of an Hog, it cureth all tumours and ſuſpitious impo-
ſtumes. Being emplaſtered with brimſtone and roſin, upon Fiſtulaes or ſuch hollow and blind
ulcers, it draweth out all the filth and corruption that lieth ranckling and feſtering within. But
lay it to a ſore with pitch, you ſhall ſee it fetch out ſpils and ends of broken arrowes ſticking ſtill
within the fleſh. The Leproſie, the running and daungerous*tettar, the red pimples alſo riſing in
the skin, Garlick doth firſt fret and exulcerate: but afterwards, with Origanum, it cureth and hea-
leth the ſame. Yea, the very aſhes of Garlick burnt, and ſo tempered with oile and the pickle [Ga-
rum] that it may take the form of a liniment, doth the like. The wild fire alſo, or ſhingles, that hath
gotten to a place, if it be annointed therewith, will bee extinguiſhed. Bee any place of the bodie
growne blacke and blew by ſtripes or blowes, a liniment made of Garlicke burnt to aſhes & tem- L
pered with honey, will bring the native and freſh colour againe quickly. There is a deepe and
ſettled opinion among men, That if a man or woman do ordinarily take Garlick with meat and
drinke, they ſhall find remedie thereby for the falling ſickneſſe. Alſo, that one head of Garlicke
taken in ſome ſtyptike and harſh raw wine, with Laſerpitium, to the weight of one Obolus, dri-
veth away the Quartane ague for ever. But after another ſort, if it be uſed, to wit, boiled with bru-
ſed Beanes, and ſo eaten ordinarily with meat; there is no Cough ſo tough, no ulcer within the
breaſt ſo foule and filthie, but it will ſtay the one, and cleanſe, yea, and heale the other, ſo as the
patient ſhall recover perfect health. Garlicke maketh folke to ſleepe well, and giveth a good,
freſh, and ruddie colour to the whole bodie. Garlicke ſtamped with greene Coriander, and
drunken with ſtrong wine, encreaſeth the heat of luſt, and provoketh to Letcherie. But as ma- M
ny good properties as Garlicke hath, it is not without ſome bad qualities for them againe. It ma-
keth the eies dim, it breedeth windineſſe & ventoſitie; it hurteth the ſtomack, overliberally taken,
and *cauſeth thirſt. But let me not forget among other vertues which it hath: namely, that if it
be given to Hens, Cocks, and other Pullein, among their corne, it will keepe them from the pip.

As

*i. The wringings and torment of the upper ſmall guts.

As for Horſes, Mares, Aſſes, and ſuch like beaſts that cannot ſtale, or be groud and wrong in the bellie: ſtampe Garlicke, and therewith rub the ſhap and naturall parts; it will provoke the one, and eaſe the other.

Chap. VII.

Of wild Lectuce, as well that called Caprina as Eſopus. Of Iſatis and Garden Lectuce.

THe firſt kind of Lectuce that groweth wild of it ſelfe without mans hand, is that which is commonly called Caprina, *i.* Goats Lectuce. This hearbe hath a propertie, that if it bee
B throwne into the ſea, it will preſently kill all the fiſhes that approch neare unto it. The milkie juice of this Lectuce being turned thicke, and ſoone after mixed with vineger, to the weight of two Oboli, and one Cyath of water put thereto, is given with good ſucceſſe to thoſe that have the Dropſie. The ſtalkes and leaves ſtamped, with ſome ſalt ſtrewed among, and ſo applied as a cataplaſme, doe heale up the ſinewes that be cut or wounded. The ſame hearb being bruſed together with vinegre, preſerveth a man from the toothach, if he uſe two mornings every moneth to waſh his mouth with a collution made thereof.

It ſhould ſeeme he meaneth here the *Tithymales*, which be *Lactariæ*.

A ſecond kind there is of wild Lectuce, which the Greekes name Eſopus. The leaves thereof being beaten in a morter and with Barley floure, applied as a pulteſſe, heale all ulcers. This groweth ordinarily in corne fields.

C A third ſort comming up in the woods, is named otherwiſe *Iſatis. The leaves whereof being likewiſe beaten together with Barley-meale or floure aforeſaid, cureth greene wounds.

** Plinie* ſhould ſeeme here to be deceived: for *Iſatis* is the ſame that *Glaſtum, i.* Woad, and the wild thereof indeed is leaved like Lectuce which was the occaſion of his error.

A fourth kind there is beſides of wild Lectuce, named Glaſtum, *i.* Woad, wherewith divers uſe to colour their wooll. It might bee likened to the wild Docke for the leaves, but that they bee more in number, and of a blacker greene withall. This hearbe ſtancheth bloud. It repreſſeth and cureth the fierie and eating tetters, the cankerous and filthie ulcers alſo which run and ſpread over the whole and ſound parts: alſo it diſſolveth ſwellings before they gather to an head, & tend to ſuppuration. The root or leaves thereof bee good againſt S. *Anthonies* fire, applied in a cataplaſme or liniment. It is a ſingular remedie alſo for the ſwelled and puffed ſplene. And thus much for their properties in particular, reſpective to each ſeverall kind. But to ſpeake generally of them
D all that grow wild, they agree all in this, that they bee white; that their ſtem groweth otherwhiles to the height of a cubit; that both it and the leaves bee rough in handeling. Of theſe wild Lectuces, That which hath round and ſhort leaves, ſome there be who call Hieracia; becauſe that Faulcons and ſuch like Haukes are wont to ſcrape and ſcratch this hearbe to get foorth the juice, wherewith they annoint and rub their eies, and thereby recover their ſight, when they perceive it to be darkened or dim. All the ſort of them are full of a white juice: & the ſame of the like vertue as is the juice of Poppies. Ordinarily is this juice gathered in harveſt by inciſion of their ſtalk: put up it is in new earthen pots never occupied, and ſo reſerved for many excellent effects that it hath. For firſt and formoſt, being applied with womans milke, it healeth all maladies which the eies be ſubject unto, as namely, it riddeth away the cloudie webs therin, the cicatrices and ſcarres:
E all filthie ſores with a burnt roofe over them, and principally diſparcleth the miſt and dimneſſe that troubleth the eie-ſight. It is uſually alſo laid with a locke of wooll to the eies, for to repreſſe and ſtay the wateriſh humor that hath found a way thither. The ſame juice, if one drinke it, to the weight of two Obolij, in vinegre and water, is a good purgation. Being taken in wine, it cureth the venomous ſtinging of Serpents. To which purpoſe, the leaves being parched and dried againſt the fire, their tender ſtems alſo being bruſed, are drunke with vinegre. A liniment made of them, is paſſing good againſt the pricking of Scorpions. But peculiarly for the ſting of the venomous ſpiders Phalangia, there muſt be wine and vinegre mixed therewith. Soveraigne defenſatives alſo theſe wild Lectuces be, againſt other poyſons; ſave thoſe that kill by ſtrangling and ſuffocation, or ſuch as have a ſpeciall ſpight to the Bladder: neither are they of any power againſt Ceruſſe
F or white Lead. A cataplaſme made thereof with honey and vinegre, and ſo laid to the bellie, purgeth the rotten humors, and expelleth the wormes thereof bred. Their juice is ſingular good for them that piſſe with paine and difficultie. *Cratevas* preſcribeth to give the weight of two Oboli of the ſaid juice, in one Cyath of wine, to thoſe that bee in a Dropſie. Some there be who draw the juice out of the garden Lectuce alſo for the ſame purpoſe, but not with like effect. The peculiar

proper-

properties of which Lectuces, I have partly written of heretofore; and namely, how they procure sleepe, abate fleshly lust, coole intemperate heats, cleanse and strengthen the stomacke, and finally, encrease bloud. Over and besides, they have other properties not a few, for they resolve and discusse ventosities, they breake wind upward, and make one rift and belch sweet, and finally, helpe digestion, and of themselves cause no cruditie in the stomacke. Certes, I cannot say of any thing else but it, that being eaten, both giveth an edge to appetite, and also dulleth the same: and all according as it is taken, more or lesse. By the same reason also, if a man eat liberally of them, they will make the bellie soluble: if in a meane, they will stay a Laske, and bring the bodie to costiveness. They cut and dissolve the grosse viscositie of slimie fleame: and as some Physicians have written, doe clarifie the Senses. Moreover, if a mans stomacke be quite gone, so that hee neither desireth to receive any thing into it, nor can hold and keepe that which it receiveth, hee shall find notable comfort by eating of garden Lectuce. But for this purpose they must bee taken unwashed, with some sharpe sauce made with vinegre, to the quantitie of a certaine Obolus, yet so, as that the tart and harsh taste thereof bee tempered with some wine cuit or other sweet liquor for to dip into. Moreover, this regard ought to bee had, that if the fleame lying in the stomacke, bee very tough and grosse, the Lectuce would bee eaten with vinegre of Squilla or the sea-Onion, or else with Woormewood wine: and if the Cough bee also busie, then Hyssope-wine would bee mingled withall. In case there bee a flux occasioned by feebleness of the stomacke, then would garden Lectuce bee eaten together with wild Endive or Cichorie: and so are they good also for the hardnesse and swelling in the midriffe and about the heart. G H

White Lectuce eaten in good quantitie, helpeth the infirmities of the Bladder, and agree very well with those who be troubled in their braines, and overcharged with melancholie. *Praxagoras* advised also, That they should bee eaten for to helpe the bloudie flixe. Moreover, if they bee laied presently (in manner of a liniment, with salt) upon a burne or scald, while it is new, and before the place blister, they will fetch out the fire, and doe very much good. They keepe downe and represse cancerous ulcers, that would be running and eating into the flesh, if they bee applied at the beginning with salt petre, and afterwards with wine. Being bruised into a liniment they heale S. *Anthonies* fire, if the place be annointed therewith. If their stalkes or stemmes be stamped with drie grout of Barley meale, and laid too as a cataplasme with cold water, they mitigat the paines that follow dislocations or lims out of joint, they assuage also dolorous crampes and convulsions. Being applied in manner of a pultesse with wine and drie Barley groats, they doe allay the greese of red and angrie wheales. Moreover, they were wont in times past to boile them betweene two platters, and so give them for the disease Cholera, wherein choler is so outrageous, that it purgeth unceasantly both upward and downeward. But for this purpose, there would bee choise made of the fairest and greatest stems, such also as are bitter, for they bee best. Some to the same effect, make a decoction of them in milke, and so minister it unto the patient in a clyster. These stalkes beeing well and throughly boiled, are said to bee verie wholesome for the stomacke also: like as, for to procure sleepe, the garden Lectuce is thought most effectuall, namely, that which is bitter and yeeldeth store of milke, which heretofore wee have tearmed Meconis. This milke Physicians prescribe with very good successe for to clarifie the eie-sight, namely, if it be mingled with womans milke, and the fore-head annointed therewith in good season and betimes. After the same manner it helpeth the infirmities and diseases of the eies, proceeding from cold causes. Other vertues and commendable properties besides I find in Lectuce, of straunge and wonderfull operations. And namely, that it cureth the diseases of the breast, as well as Sotherne-wood dooth, if it bee taken with the best honey of Athens. *Item*, That if any women doe eat thereof, they shall have their monthly sicknesse come orderly. Also, that the seed of garden Lectuce is given to verie great purpose against the pricke or sting of any venomous Scorpion. Moreover, that if the seed bee stamped and taken in wine, it secureth one from the imaginarie fansies of *Venus* delights, in sleepe, and the pollutions also that thereof doe ensue. Finally, that certaine waters which use to entoxicat and trouble the braine, shall never hurt them that eat any Lectuce. Howbeit, some are of opinion, That the over-much use of Lectuce at meat enfeebleth the eies, and empaireth their cleare sight. I K L M

CHAP.

Chap. VIII.

Of Beets and their ſundrie kinds. Of Endive. Diverſe ſorts of Cichorie. Of garden Endive, and two kinds thereof.

THe Beets of both ſorts are not without their medicinable vertues: for bee it the white or the blacke, if one take the root thereof freſh and new out of the ground, wet it throughly, and ſoke it well in water, and then carie it about him hanging by a ſtring or lace, it is a ſoveraigne preſervative againſt the biting of Serpents. The white Beet boiled and eaten with raw Garlicke, expelleth the broad wormes in the bellie. The roots of the black, ſodden after the ſame manner in water, rid away the dandruffe or unſeemely skales within the haire of head or beard. And indeed generally for any uſe, the blacke Beet is more effectuall than the white. The juice thereof is ſingular good for an old and ſetled head ach. For the dizzineſſe or ſwimming in the head. Alſo, it riddeth away the ſinging and ringing in the eares, if it be dropped into them. It procureth urine: Being injected by a clyſter, it cureth the bloudie Flixe: it helpeth alſo the launise. Moreover, the ſaid juice appeaſeth the intollerable paine of tooth-ach, if the teeth be rubbed or annointed therewith. Singular it is againſt the ſtinging of Serpents: but then it muſt be drawne from the root onely. And make a decoction of the ſaid root, it helpeth kibed heeles. As for the juice of the white Beets, it ſtaieth the Rheume or watereſh humour that falleth into the eies, if the fore head be therewith annointed. And put but a little Allum thereto, it is an excellent remedie againſt S. *Anthonies* fire. White Beets only ſtamped, although there come no oile unto them, healeth any burne or ſcalding, if the place be therwith annointed. Moreover, againſt the breaking out into red and angrie pimples, the ſame is very good. But ſeeth Beets, and make thereof a liniment, it repreſſeth the ulcers that run and ſpread abroad. The ſame being raw, rubbed upon the bare places, where the haire is ſhed, recovereth haire, yea, and ſtaieth the running skalls of the head. The juice of theſe Beets tempered with honey, and ſnuffed up into the head by the noſthrils, cleanſeth the braine. There is a certaine meat made with * Beets and Lentils boiled together, which commonly is eaten with vinegre for to make the bodie laxative. The ſame being overſodden to a thicke conſiſtence, ſtaieth both the turning of the ſtomacke, and flux of the bellie.

* πυτιλοφάκη.

There is a kind of wild Beet, which ſome name Limonion, others Neuroides: it hath leaves much leſſe and tenderer than the other, howbeit, growing thicker: and riſeth up many times with eleven ſtalkes. The leaves of this Beet are very good for burnes and skalds: they reſtraine and ſtaie all Fluxes by drop meale, which breed the Gout. The ſeed being taken to the quantitie of one Acetabulum, cureth the bloudie Flix, & healeth the ulcer of the guts that cauſeth the ſame. Some ſay, that if this Beet be ſodden in water, the decoction will ſcoure and take out any ſtaine in cloths, even the very yron-mole: likewiſe it will waſh away any ſpots in parchment.

Now as touching Endive or garden Cichorie, furniſhed alſo it is with many properties effectuall in Phyſicke. The juice thereof mingled with oile Roſat and vinegre, allaieth the paine in the head. The ſame if it be drunke with wine, is good for the liver and the bladder. Alſo, if it bee laid to the eies, it ſtoppeth the humour that hath taken a courſe thither. The wild Cichorie that groweth wandering here and there abroad, ſome of our Latin writers name * Ambugia. In Ægypt they call the wild Endive, Cichoreum; & the tame garden Endive, Seris: the which indeed is leſſe than the other, fuller alſo of ribs and veines. As for the wild, which is Cichorie, it hath a cooling nature, being eaten as meat: but applied in forme of a liniment, it is good againſt the collection of humors that engender impoſtumes. The juice of it ſodden, dooth looſen the bellie. Wholeſome it is for the Liver, the Kidneies, and the Stomacke. Likewiſe, if it bee boiled in vinegre, it reſolveth the painefull torments occaſioned by the ſtopping or difficultie of urine, and openeth paſſage to make water at eaſe. Moreover, if the juice or decoction thereof bee drunke with honied wine, it cureth the laundiſe, ſo it be without a fever. It is comfortable alſo & helpefull to the Bladder. Boiled in water, it is ſo powerfull to bring downe womens tearmes, that it is of force to ſend out the child, if it be dead in the mothers bellie. The Magicians ſay moreover, that whoſoever annoint their bodies all over with the juice of this hearbe & oile together, they ſhall be right amiable, and win the grace and favour of all men, ſo as they ſhall the more eaſily obtain whatſoever their heart ſtands unto. And verily, for that it is ſo ſingular and wholeſome to mans bodie, ſome give it the name of χρησὸν, others of πάνακρατιον.

* or rather *Ambubeia.*

As

As for another wild kind, ſome call it * Hedypnois, and that hath a broader leaſe than the reſt. Being ſodden, it is aſtrictive and will ſtrengthen a weake ſtomacke: and eaten raw, it bindeth the belly and ſtayeth the laske. Holeſome it is for ſuch as have the bloudie flix, the rather if it be taken with Lentils. In ſumme, as well raw as ſodden, both kinds the one and the other, help thoſe that have cramps and ruptures. Comfortable it is likewiſe to ſuch as upon occaſion of debilitie or ſickneſſe, have their nature or ſeed run from them againſt their wills. G

* For that being eaten with meat, it maketh the breth ſweet.

Touching Cichorie of the garden, which is very like unto the Lectuce, there be two kinds thereof; but the greene that ſeemeth to bee of a wild and ſavage nature, is the better: of a more brown and duskiſh colour it is, and a Summer hearb onely. The other indeed is whiter and continueth all winter, howbeit worſe of the twaine: and yet both the one and the other, are right comfortable to the ſtomacke, eſpecially when it is overcharged with wateriſh humors. Beeing eaten in a ſalad with vinegre at meat, they refreſh and coole mightily: ſo doe they alſo in forme of a liniment, and by that means reſolve other humors beſides thoſe in the ſtomacke. Generally the roots of all wild Cichories being ſodden with barley grouts to a gruell, and ſo ſupped off, do comfort a weake ſtomack. Being reduced into a liniment, and applied to the region of the heart above the left pap, with vinegre, they cure the trembling thereof, and the faint cold ſweats that breake out upon weakneſſe. All the ſort of theſe Cichories as well tame as wild, beeing taken in broth each other day, be good for goutie perſons, for ſuch alſo as reach and caſt up bloud, ſhed their ſperme or have the running of the reins. Howbeit *Petronius Diodotus* in his booke entituled * Contradictions, utterly condemned the garden Endive Seris, and alledged many reaſons and arguments to confirme that poſition of his: howbeit the whole colledge of all Phyſicians beſides, ſtand againſt him. H

* *Antilegomena*, ſome read ἀπολογούμενα, i. ſhifte gatherings. I

Chap. IX.

Of Garden Coleworts, Lapſana, Sea Coleworts, or Soldanella: of Squilla: of other bulbous roots, as the Potatoes: and of Bulbium.

THe commendable proprieties of the Colewort are ſo many, that it were a long labour to diſcipher them all, conſidering that both *Chryſippus* and *Dieuches*, two Phyſicians, have compiled each of them a booke particularly of this hearb, wherein they have collected their vertues, as they be appropriat and reſpective to every part of mans bodie; yea and before all others, *Pythagoras*, and after him *Cato*, have as amply ſet out the praiſes thereof. As for *Catoes* opinion and judgement of the ſaid hearb, I am the more willing in this place to ſet downe and follow diligently, becauſe it might be knowne what ſimples and what drugs they were which the old Romans uſed for their Phyſicke * ſix hundred yeeres after the foundation of the cittie. The Greeke writers of greateſt antiquitie, have made three kinds of Coleworts; to wit, the criſped or ruffed Cole, which they called Selinas or Selinoides, for the reſemblance that the leaves have to Parſley: Theſe Coleworts bee good for the ſtomacke, and gently looſen the belly. The ſecond ſort is named in Greeke * Lea, with broad leaves ſpringing forth from a great ſtem: wherupon ſome have given it the name of * Caulodes: Theſe woorts are to no uſe at all for Phyſicke. The third is properly called by the name of Crambe; very well ſtored with leaves this is, but thoſe are ſmaller than the reſt, ſimple alſo & plain: bitterer beſides this Cole is in compariſon of others, but moſt effectuall in Phyſicke. Howbeit *Cato* preferreth before all, that which is criſpe and frizled: next unto it, the ſmooth Cole, with the large leaſe & big ſtalke. He commendeth the Colewoort (ſtamped raw togither with vinegre, honey, Coriander, Rue, Mints, and the root of Laſer) to be ſingular good for the head-ach, the miſt and dimneſſe of the eyes, the appearance of ſparkling motes before them, the ſtomack and precordiall parts; if a man take faſting two Acetables of this compoſition. And hee ſaith moreover, that this confection is ſo ſoveraigne, that they who doe but bray & beat the ingredients, ſhall ſenſibly find themſelves mightily comforted and fortified thereby. And he concludeth withall, that Coleworts may be either ſtamped togither with the foreſaid *ſpecies*, and ſo taken in a ſupping; or els be eaten, firſt dipped and ſoked in the forenamed liquor: as alſo that a liniment made of them, togither with Rue, a little Coriander, ſome few corns of ſalt, and barley meale; is ſoveraigne for to aſſuage the paines of any gout, be it in feet, hands, or any other joynt whatſoever. Moreover, that a decoction made thereof, doth wonderfully comfort and fortifie the ſinews, yea and mitigat the arthriticall griefes or joynt-ach, K

* For about that time *Cato* lived.

* *i.* Smooth and plaine.
* *i.* The ſtemmie Cole. L M

A if the parts be tormented therewith. Over and beſides, a fomentation made therewith, is ſingular for all freſh wounds, old ulcers, yea and cankers, which could not poſſibly be repreſſed or healed by any other medicines: but he appointeth firſt that they be bathed in hot water, and then a cataplaſme of the ſaid woorts to be laid upon the afflicted place, and the ſame to bee refreſhed twice a day. By which manner of cure, he ſaith, that fiſtulous ſores may be healed, diſlocations ſet ſtreight, ſwellings and impoſtumes drawn outward to an head; or otherwiſe where need is, diſcuſſed and reſolved, before they tend to ſuppuration. He addeth moreover and ſaith, That whoſoever eat good ſtore of ſodden Coleworts, togither with oile and ſalt faſting in a morning, ſhall fall to ſleepe again in the night if they were before overcharged with watching; and in their ſleep ſhall not be troubled with dreams or other unquiet fanſies and imaginations. Furthermore hee
B affirmeth, That worts twice boiled, are excellent good for the torments and wrings of the belly, ſo there be joyned to the ſecond decoction, oyle, ſalt, cumin, and barley groats: and thus beeing eaten without bread, they are the better. Among other effects that theſe Colewoorts doe worke, this is not to be forgotten, That they purge chollericke humours, beeing taken with ſweet groſſe wine. More than that, he avoucheth; That if his urine who uſe to feed of Coleworts, be reſerved, it is ſingular good for the ſinews, if the grieved part be bathed therein after it is made hot againe. But becauſe you ſhould fully underſtand his meaning, I care not much to ſet downe his verie words for to expreſſe the ſame the better. If (quoth hee) you waſh little children with the ſaid urine prepared in manner aforeſaid, they will never be weake and feeble in their lims. Hee adviſeth moreover, to drop the juice of Colewoorts warme into the ears with wine, and aſſureth us
C that it is good for them that be hard of hearing. Finally, that ringworms, tettars, itch, and drie skabs (ſuch as be not exulcerat) are healed thereby.

Now concerning the opinion of the Greeks alſo, as touching Coleworts, I thinke it meet to ſet them down for *Catoes* ſake, I mean touching thoſe points onely that he overpaſſed and omitted. Firſt and foremoſt therefore, the Greeks hold, that the Colewort not being throughly ſodden, purgeth choller and keepes the bodie ſoluble; howbeit twice ſodden, it bindeth the bellie. *Item*, That it is contrarie to wine, and a verie enemie to vines. And more particularly, if it be taken faſting, or in the beginning of a meale before other meat, it preſerveth a man from drunkenneſſe; and eaten after meat when a man is drunken indeed, it riddeth away the fumoſities in
D the braine, and bringeth him to be ſober. Alſo, that it is a meat appropriat to the eyes, and cleareth the ſight very much; inſomuch as the juice of it raw is paſſing ſoveraigne for that purpoſe, in caſe it be mingled with the pure Atticke honey into an eye-ſalve, and therewith the corners of the eyes be but touched onely. Moreover, that it is paſſing light of digeſtion, & clarifieth all the ſenſes, if it bee ordinarily eaten. *Eraſiſtratus* and all his ſchoole doth ring and reſound againe with one voice and open mouth, That there is nothing in the world better for the ſtomacke, nothing more holeſome for the ſinews; and therfore with one accord they preſcribe the uſe therof, for thoſe that have the palſie or reſolution of the nerves; for as many as be trobled with the trembling and ſhaking of their lims; to ſuch alſo as reach and caſt up bloud. *Hippocrates* giveth counſell to them that be afflicted with the bloudie flix or exulceration of the guts; to thoſe likewiſe who be ſubject to the flux proceeding from the weakneſſe of the ſtomacke, for to eat it twiſe ſod-
E den with ſalt. Alſo he preſcribeth it in the cure of Tineſmos [which is a provocation or extraordinarie appetite to ſeege, without doing any thing;] and of the paine in the backe or reines. And he is of this judgement, That women in childbed ſhall be good nources and have plentie of milke, if they eat of Cabbages or Coleworts; yea and women in generall, by feeding thereupon, ſhall ſee their monethly tearmes duly. As for the Cole it ſelfe, if it be chewed raw, it is (by his ſaying) of force to expell a dead infant in the wombe. *Apollodorus* holdeth reſolutely, That either the ſeed or juice thereof taken in drinke, is a ſingular remedie for them who ſuſpect that they have eaten venomous muſhroms. *Philiſtion* giveth the juice thereof in Goats milke, togither with ſalt and honey, unto ſuch as have a cricke or crampe drawing their necks backward, that they are not able to turne their heads. I find moreover, that by eating Coleworts at meat
F ordinarily, and by drinking the decoction thereof, many have been delivered from the gout. It is an uſuall medicine and approoved by experience, to give it with ſalt for the fainting ſweats and trembling of the heart; as alſo for the falling evill. Such as be troubled with the ſplene, find much eaſe thereby, if they continue drinking the juice therof in white wine at their meales fortie daies togither: like as, thoſe that bee ſped with the yellow Iauniſe, or in fits of phrenſie, bee cured with

gargling and drinking the juice of Cole-roots raw. But againſt the Hocquet or Yex, there is a notable medecine made with it, togither with Coriander, Dill, Honey, Pepper, and Vinegre. If the pitch of the ſtomacke bee annointed therewith, the Patient ſhall evidently perceive, that it will diſſolve the wind and puffing ventoſities therein. Alſo, the very water of the decoction incorporat togither with Barley meale, unto a liniment, is ſingular good for the ſtinging of Serpents, and mundifieth filthie old ulcers: to which purpoſe alſo, ſerveth the juice thereof, applied with vinegre and Fænigreeke. After the ſame manner, ſome make a cataplaſme, and apply it to goutie joynts. The bloudy falls and bliſtring chilblanes, and generally all humours that over-run the bodie and fret the skin, are allaied by the application aforeſaid. In like manner, the ſodaine miſts and dimneſſe which commeth over the eyeſight, is diſcuſſed and diſpatched cleane, in caſe one doe no more but chaw this hearb in vinegre. A liniment made with it and * brimſtone togither, helpeth the black and blew ſpots of dead bruiſed bloud lying under the skin, and reduceth them to their owne colour. But if round alume and vinegre be joyned therewith, it cureth the white leproſie and drie skab [called of ſome S. *Magnus* evill.] And in that manner prepared, it keepeth the haire faſt that is readie to ſhed. *Epicharmus* ſaith, That this hearb is ſoveraigne good to be emplaſtred upon thoſe tumors and ſwellings that bee incident to the privie members, and the rather, if the ſaid emplaſtre be made with beane meale. The ſame being applied with Rue, is good for convulſions or cramps. Moreover, there is a medicine preſcribed to bee made of Colewoorts and Rue ſeed, againſt the extreame heat of fevers ardent, as alſo for the defects and infirmities of the ſtomacke, and to ſend out the after-birth in women newly laid. The powder of Colewort leaves drie, doth expell and evacuat one way or other, the venome left behind by the biting of the hardie ſhrew-mouſe. Of all kinds of Coleworts, the ſweeteſt and moſt pleaſant to the taſt, is the * Col-florie, although it be counted good for nothing in Phyſicke, and beſides unholeſome, as being hard of digeſtion and an enemie to the kidnies. Over & beſides, I muſt not forget this one thing of Coleworts, That the broth or decoction thereof (ſo highly praiſed for many good uſes that it is put unto) if it be poured on the ground, hath but a ſtinking ſmell with it. Wort-ſtocks beeing dried and burnt into aſhes, is thought to be a cauſticke medecine or potentiall cauterie. The ſame aſhes mingled with old greaſe and reduced into a cataplaſme, helpeth the paine of the Sciatica: but with Laſer and vinegre, it is a depilatorie, that is to ſay, keepeth the haire from growing againe where it was once fetched up by the roots. The ſaid Cole-ſtocke aſhes ſet over the fire untill it ſiver only, or have one walme at the moſt, and ſo drunke with oile, or otherwiſe ſodden, and the decoction taken alone without oile, is good for Spaſmes and cramps, for inward bruiſes, and for ſuch as are falne from ſome high place. Loe, what a number of praiſe-worthie vertues are recounted of Coleworts! And is there (I pray you) no fault to be found with them? are they blameleſſe? ywis no: For even thoſe writers who extolled them ſo highly, note them for making a ſtinking breath, and for hurting the teeth and gums: inſomuch as in Ægypt, they be in ſo bad a name for their bitterneſſe & unpleaſant taſt, that no man knoweth how to eat them. But to come againe unto *Cato*, hee commendeth the effects of the wild or wandring Colewoort infinitly above the reſt; inſomuch as hee affirmeth, that the powder of it dried, being gathered and incorporat with ſome convenient liquor into the forme of a pomander, or otherwiſe ſtrewed upon any poſie or noſegay, ſo as it may be received and drawn up into the head by the noſthrils, cureth the * filthie ulcers growing therein, and the ſtinking ſmell that commeth from them. This Colewort, others call Petræa, and this is that which of all the reſt is moſt adverſe and the greateſt enemie to wine; this is it that the vine (by a ſecret Antipathie in nature) doth eſpecially avoid, if it have roome to decline from it: but in caſe ſhe cannot ſhift from it, ſhee dieth for very griefe. This plant hath the leaves growing two by two togither, and thoſe ſmall, round, ſmooth, and liker indeed to the young plants of * Beets than to other Coleworts; whiter alſo it is, and more rougher clad with a moſſie downe, than is the garden Colewort. *Chryſippus* writeth, That it is a ſoveraigne medicine for flatuoſities, and ſuch as be oppreſſed with melancholly: that it is a ſingular ſalve for freſh wounds, beeing applied with honey; but with this charge, That the plaſter be not taken off in ſeven daies. Alſo, if it bee ſtamped and applied with water, it is an excellent cataplaſme for the Kings evill, & fiſtulous inward ulcers. Other Chirurgians and Phyſicians do affirme, that it repreſſeth running and corroſive ſores which eat into the fleſh, ſuch as the Greekes name Nomus. *Item*, that it doth extenuat and reſolve all excreſcence of proud, ranke, or dead fleſh: yea and it doth incarnat, heale up, and skin very faire

without

*Cum Sulphure illita.

*Cyma.

* Some call the *Polypi*.

* *Oleris.*

A without skar, by their saying. Moreover, if it bee chewed, or the juice thereof gargarized with honey, so that the hearb were sodden before, it cureth the sores in the mouth called Cankers; as also the mumps and inflammation of the kernels in the throat, called Amygdales or Almonds. Semblably, if a man take two parts of this hearbe, with twaine of alume, and togither with vinegre make a liniment thereof, it will cleanse the inveterat drie skab, and the mortified leprosie. *Epicharmus* is of opinion, That for the biting of a mad dog, a man need doe no more but lay to the sore place a cataplasme of this herb alone: but surer it were (saith he) and more effectuall, if Laser and strong sharpe vinegre were joyned thereto. He addeth moreover and saith, That if it be given to dogs with some peece of flesh, it will kill them. And yet the seed being parched, is a remedie against the sting of Serpents, and a countrepoison to venomous mushroms and bulls
B bloud. The leaves boiled and given with meat, or otherwise raw and made into a liniment, togigither with brimstone and nitre, helpe those that be diseased in the splene. The same liniment mollifieth the hard swellings of womens breasts. The ashes of the root being burnt, cure the Vvula or swelling of the wezill in the throat, if it be but touched therewith. Also a liniment therof with hony applied to the inflamed kernels behind the ears, represseth them; yea and healeth the stinging of Serpents. I have not yet done with the Colewort, and the vertues thereof; but one instance more I will give you to proove the woonderfull force and effect that it worketh: If any brasse pot, caudron, or such like vessell, wherein we use to seeth water over the fire, have gathered in continuance of time, a thicke fur or crust baked within, such as by no washing or scouring can be rid away, be the same never so hard, deepe setled, and inveterat; boile but a Cabbage or
C Colewort in it, and the same will pill and go from the pot sides.

Among wild Woorts, we must place Lapsana, a plant growing to the heigth of a cubit, bearing a furred or hairie leafe, like for all the world to the Navew, but that the floure is whiter. This hearb is commonly sodden and eaten in pottage; and so taken, it moderatly looseneth the belly.

The Sea Colewort [otherwise named Soldanella] of all others purgeth most forcibly: in regard of which acrimonie that it hath to stir the belly, cooks use to seeth it with fat meat, and yet is it most contrarie to the stomacke.

Touching Squills or Sea-onions, Physicians hold, that the white is the male, and the blacke the female: but the whitest of them be ever best and of most use. The manner of preparing and dressing them, is after this manner: First, the drie tunicles or skins being pilled off, the rest which
D is quicke and fresh underneath, must be cut into slices, and so enfiled upon a thread along, with a pretie distance between every one, and hanged up to drie: afterwards, when the morcels be sufficiently dried, they are to be put (hanging still as they did by a string) into a barrell or vessell of the strongest and quickest vinegre that can bee gotten, and therein they must hang, so as they touch no part of the said vessell: But this would be gone in hand with 48 daies before the Summer Solstice. Which done, the barrell of vinegre beforesaid being well luted and stopped close with plastre, must bee set under a roofe of tyles, to receive the heat of the Sun, all the day long from morning to night. Now when it hath been thus sunned so many daies, as are before named, the vessell is remooved from under the case of tiles, the Squilla taken forth, and the vinegre poured out into another vessell. This vinegre clarifieth their eye-sight who use it: comfortable it is
E to the stomacke and sides, and assuageth their paines if it be taken in small quantitie once in two daies: for if a man should drinke over liberally of it, so forcible it is that it would take away his breath, and cause him to seeme dead for the time. Squilla chewed alone by it selfe, is holesome for the gums and teeth. Being drunke with vinegre and hony, it chaseth out of the belly the long flat wormes, and all other such like vermin. If it bee but held under the tongue while it is greene and fresh, it allaieth thirstinesse in the dropsie, and causeth that the Patient shall desire no drinke. The boiling of Squilla or the Sea-onion, is after many sorts: for some, after they have either well luted, or els greased it all over with fat, put it into a pot of earth, and then set it into an oven or furnace to be baked. Others slice it into gobbets, and so seeth it between two platters. Some take it greene, and drie it, then they cut it into pieces and boile it in vinegre; and being thus used
F and prepared, apply it to the places which be stung with Serpents. Others again rost it first in the embres, and after they have cleansed it from the utmost pilling, take the best of it onely in the mids, and seeth the same againe in water. Being thus baked and sod both, it serveth to bee given in a dropsie. And if it be drunke to the quantitie of three Oboles with honey and vinegre, it provoketh urine with ease. In like manner, this composition is good for those that be troubled with

the ſplene, or have weake and feeble ſtomacks, or bee troubled with gnawing and paine there; G
ſuch alſo as cannot hold their meat, but it will flote above and come up again: provided alwaies, that there bee no ulcer within the bodie. Moreover, it is excellent good for the wringing in the guts, the jauniſe, the old cough, with ſhortneſſe of wind. The leaves emplaſtred, reſolve the wens or ſwelling kernels in the necke, commonly called the Kings evill, but they muſt lie foure daies before they be remooved. Beeing ſodden in oile and reduced to a liniment, and ſo applied, it mundifieth the skurfe or dandruffe in the head, the running ſcalls likewiſe that are bred there. It is uſually alſo (boiled up with honey into a certaine confection) taken with meat for to helpe digeſtion; and in that ſort it purgeth alſo the entrails. Sodden in oile and tempered with roſin, it healeth the chaps and clifts in the feet. The ſeed of Squilla emplaſtred with hony upon the reins of the backe or the loins, eaſeth the paine. *Pythagoras* was of opinion, and ſo reported, That if H
the Squilla or Sea-onion were hanged up in the entrie of any dore, it kept out all charmes, enchantments, and ſorceries. And thus much of Squilla.

Moreover, the plants called Bulbes, beeing applied in forme of a liniment with brimſtone and vinegre, doe cure the wounds of the viſage: and ſtamped by themſelves alone, and ſo laid too, they help the contraction or ſhrinking of ſinews: and if there be wine added thereto, it clenſeth the dandruffe in head, beard, and eyebrowes: but applied with honey, it cureth the biting of mad doggs: howbeit *Eratoſthenes* taketh pitch in ſtead of honey for the ſaid purpoſe: who writeth beſides, That a cataplaſme of them and honey togither, ſtaunceth blood in a greene wound: but others joyne Coriander and corne meale to the reſt, properly for bleeding at the noſe. *Theodorus* cureth wild tettars and ringwormes therewith, being applyed with vinegre: and I
with ſtypticke harſh wine, or an egg, he uſeth it for the breaking out in the head. Moreover, a liniment made of Bulbs, he applyeth about the rheumaticke humors that fall to the eyes, and by that means cureth thoſe that be bleere-eyed. Semblably, the red of this kind eſpecially, reduced into a liniment, and firſt incorporat with honey and nitre, taketh away all the ſpots and blemiſhes that disfigure the face, if they bee annointed therewith in the Sun: but with wine and Cucumber ſodden, they rid away alſo the red pimples. They bee wonderfull good of themſelves alone, for greene wounds; or with honyed wine (according to the practiſe of *Damion*) ſo they be not remooved in five daies: and he was wont therewith to cure cracked ears alſo, and the flatuous flegmaticke tumors of the cods. Others there bee, who apply them with meale mingled among, to aſſuage the paine of the gout. Sodden in wine, and ſo applied as a liniment to the belly, they K
mollifie the hardneſſe in the precordiall parts & midriffe: and for the bloudie flix a drinke made thereof, togither with raine water and wine, is a ſingular remedie. Beeing taken in pills as big as beans, with Silphium, they are ſoveraigne for the contraction of nerves or inward cramps within the bodie. Stamped into a liniment, they reſtraine immoderat ſweats that be diaphoreticall. Comfortable they bee to the nerves, and therefore they are preſcribed and given, in caſe of the palſie. Thoſe with the red roots beeing made into a cataplaſme with ſalt and honey, doe ſpeedily cure the diſlocations of the feet that be out of joynt. The Bulbs of Megara eſpecially, doe provoke luſt. As for thoſe that be called Hortenſij, taken with cuit wine or Baſtard, make ſpeedie deliverance of the child out of the mothers bellie. The wild Bulbs brought into the forme of pills with Laſerpitium, and ſo ſwallowed downe, doe heale inward wounds and other maladies of the L
entrails. The ſeed of the garden Bulbs in wine, is a good potion againſt the ſting of the Spiders called Phalangia: and the roots with vinegre ſerve for a liniment againſt the ſtings of other Serpents. The auncient Phyſicians in times paſt, were woont to give the ſeed in drinke to them that were out of their wits. The floure of theſe Bulbs being bruiſed into a cataplaſme, taketh away the red dapled ſpots in their legs who have ſit neare the fire and burnt their ſhins. But *Diocles* is of opinion, that all theſe Bulbous plants doe dim the eyeſight: who ſaith moreover, That they are not ſo good boiled as roſted, and yet be they all (ſaith hee) hard of digeſtion more or leſſe, according to the nature of each one that eateth them.

There is an hearb which the Greekes call Bulbine, with a red bulbous root, and leaves reſembling Porret: of which there is a ſingular good ſalve made for to heale greene wounds, but none M
elſe. To conclude, as touching the Bulbe called Vomitorius (of the effect that it hath to provoke vomit) it hath blackiſh leaves, and thoſe longer than the reſt.

CHAP.

A

Chap. x.

Of Garden Sperages, and the wild Sperage Corruda: of Lybicum and Hormenium.

OF all Garden hearbs, the Sperages are (by report) the beſt meat to bee eaten, and agree paſſing well with the ſtomacke: and verely beeing taken with Cumin, they diſſolve the ventoſities in the ſtomacke, and diſpatch the wind cholique, and withall they cleare the ſight paſſing well. Kindly doe they mollifie the belly and keepe it ſoluble. If they be ſodden in wa-
B ter, and a little wine put thereto in the boiling, and ſo given to drinke, they are very good for the paine of the breaſt and the backbone; for the diſeaſes alſo within the guts. If one take the weight of three Oboli of the ſeed, and as much of Cumin, and ſo drinke it in ſome convenient liquor, he ſhall find a ſingular remedie for the paine of the reins, haunch, and loines. Garden Sperages ſollicit unto the game of love, and procure good deliverance of urine; for which they had no fellow, but for feare that they will fret and exulcerat the bladder. Moſt Phyſicians doe highly commend their roots bruſed and taken in white wine, for to expell the ſtone and gravell; as alſo, to allay the pains of the reins, flanks, and loins. Some there be, who give to drinke in ſome ſweet wine the ſaid root, for the grievous pains of the matrice: and the ſame being well and throughly boiled in vinegre, is a ſoveraigne remedie for the leproſie, to as many as will uſe to drink the ſaid
C decoction. If a man bee annointed with Aſparagus or Garden Sperage, ſtamped togither with oile and ſo made into a liniment, there will not (by report) a Bee come neare for to ſting him.

The wild Sperage, ſome name it Corruda, others Lybicum, but the Atheniens call it Hormenium: this hearb is more effectuall in all thoſe matters above rehearſed than the former, and the whiter that it is, the greater force it hath. The jaundiſe it doth diſſipat and drive away. When it is ſodden in water, the decoction thereof to the quantitie of a * wine pint or ſomewhat leſſe, is * *Hemina.*
uſually preſcribed to them that deſire to performe the act of generation luſtily. For the ſame purpoſe alſo, the ſeed thereof and Dill, of each three Oboli, is counted very good beeing taken in drinke. The juice thereof boiled, is given againſt the ſtinging of Serpents. The root of it and Fennell togither, is thought to be moſt ſingular and of greateſt efficacie in that caſe. For piſſing bloud, *Chryſippus* preſcribeth to give in two cyaths of wine, for five daies togither, three Oboli
D of the ſeed of Aſparagus, Parſley, and Cumin: but hee ſaith withall, That this medecine is nothing good for the dropſie, notwithſtanding that it is diureticall and provoketh urine. Alſo that it is adverſe and contrarie to the delights of *Venus*, yea and to the bladder, unleſſe the ſame ingredients be ſodden; and yet will that decoction kill dogs if it be given unto them. To conclude, the juice drawne out of the root thereof, being firſt boiled, and ſo held in the mouth, is good for the teeth.

Chap. xi.

Of Parſley, wild Ach, of Smallach, and Ach of the mountains.

E PArſley is in great requeſt, and no man lightly there is but loveth it: for nothing is there more ordinary, than to ſee large branches of Parſley good ſtore, ſwimming in their potage: and commonly you have not a ſalad or ſawce ſerved to the bourd, you ſee not a peece of meat farced or ſeaſoned, but Parſley carrieth therein a great ſtroke, and contenteth every bodie. Over and beſides, if it be applied as a liniment, togither with hony unto the eyes, ſo that they be fomented alſo ever and anon with the hot juice of Parſley boiled, it is a ſingular remedie for the humors diſtilling thither. Alſo, if it bee but ſtamped by it ſelfe alone, or els with bread or barley groats, it wonderfully helpeth the defluxion falling upon any other part, if the ſame be laid upon the place afflicted in manner of a cataplaſme. Moreover, if a man perceive that the fiſh in any pond or ſtew do miſlike and grow ſickly, it is a common practiſe to give them green Parſley for to ſcoure and refreſh them. Howbeit, for all that Parſley is ſo good, there is not an hearb growing
F upon the face of the earth, that learned men varie and diſagree in opinion more about, than they doe in it; & yet they hold all, that there is a diſtinct difference therin by the ſex: for of the Parſley there is both male & female; mary which is the one and which the other, they accord not. *Chryſippus* ſaith, That the female hath more criſpe and curled leaves than the male, and thoſe boiſtrous and hard; that the ſtalk is thick, and the taſt of the herb biting & hot. *Dionyſius* deſcribeth it

to be more blackiſh, having a more ſtubbed & ſhort root, & that it is apt to breed little worms. Both of them jumpe in this, that it is not to be admitted to the table, nay, they forbid to eat of it at all, making a matter of conſcience once to touch it as a meat: and why ſo? becauſe, forſooth, it is one of the viands ordained to bee ſerved up at funerall feaſts. Over and beſides, Perſeley is thought to be an enemie to the eies, and to trouble the ſight. Alſo that the ſtem of the female engendreth grubs & ſuch like wormes: and ſo, whoſoever eateth therof, man or woman ſhall therby become barren. Moreover, they affirm, That if women newly delivered, or ſuch as nurce children, do eat of Parſely, the babes that ſuck and draw their breaſts, ſhall be ſubject to the falling ſicknes. And yet of the twain, the male is leſſe hurtfull: which is the very reaſon, that it is not condemned among the forbidden hearbs and ſuch as be held unlawfull to be eaten. Perſely being laied as a cataplaſme to womens breaſts, doth mollifie their hardneſſe, and breake the kernils. It giveth a pleaſant taſt to any water wherein it is ſodden. The juice of this hearb, and eſpecially of the root being taken in wine, doth mitigate the paines in the loines and flankes: and being dropped into the eares, cureth the hardneſſe of hearing. The ſeed of Perſely moveth urine, draweth down womens floures, and fetcheth away the after-birth. Seeth the ſaid ſeed, and with the decoction bath the blacke and blew markes remaining after ſtripes or drie blowes, it will bring them to their own colour againe. The ſame being laid as a liniment with the gleire or white of an egge unto the reines of the backe, or beeing ſodden in water, and the broth drunken, eaſeth their paines and ſtrengtheneth them. Being bruſed & uſed in cold water by way of a collution, it cureth the cankers or ulcers in the mouth. The ſeed drunk with wine, breaketh the ſtone of the Bladder: So doth the root of it alſo if it be given in old wine. Alſo the ſaid ſeed in white wine cureth the Iaunife.

As touching our wild Ach, which we call in Latine* Apiaſtrum, *Hyginus* verily nameth it Meliſſophyllon. A venomous hearbe this is in Sardinia, and by all writers confeſſion utterly condemned: for ſurely I cannot chuſe but raunge together in one ranke all ſuch as ſeeme to depend upon one name in Greeke.

*It ſeemeth that he meaneth by *Apiaſtrum* a kind of *Ranunculus*, i. Crow-foot, called *Flammula*, our Spere-wort, or *Apium riſus*.

But Aliſanders, which the Greekes tearme Hippoſelinum is a good counterpoiſon againſt the biting of Scorpions. If the ſeed bee taken in drinke, it cureth the wrings and torments of the guts. The ſame being boiled and drunke with honied wine, helpeth the Strangurie and difficultie of making water. The root ſodden in wine, expelleth ſtone and gravell by urine: it putteth away alſo the paine of the loines, flankes, and ſides. Taken in drinke, or applied as a liniment, it healeth the biting of a mad dog. The juice thereof in drinke, heateth them that are readie to chill and be frozen with cold.

A fourth kind of Ach or Perſely ſome have made that, which the Greekes call Oreoſelinum. A plant this is, growing to the height of a ſpan, and *upright. The ſeed reſembleth Cumin, and is found effectuall to procure urine and provoke womens tearmes. Finally, as Smallage hath a propertie and vertue by it ſelfe to heale the pricke or ſting of the venomous Spiders: ſo this mountaine Ach or Perſeley of the hill, being taken in wine, is as effectuall to bring downe the naturall purgation of women.

*Whereby ſome read *Orthoſelinum*.

Chap. xii.

Of Stone-Perſely, named Petroſelinum: and of Baſill.

There is another kind of Ach or Perſely growing upon rockes, which ſome call Petroſelinum. An excellent hearbe for foule impoſtumes and botches uſed in this manner: Take two ſpoonefuls of the juice thereof, put it into a Cyath of the juice of Horehound, & mingle all together in three Cyaths of water, and ſo drinke it hote. Some have ſet in the raunge of theſe Aches, that which is called Buſelinon: which differeth from the garden Perſely, in that it hath a ſhorter ſtalke, and a root of red colour: but of the ſame operation and effect it is. For both taken in drink, & applied as a liniment, it is of great power againſt the ſtinging of Serpents.

Alſo, *Chryſippus* mightily crieth out upon Baſill, as being hurtfull to the ſtomacke, ſuppreſſing urine, and an enemie to a cleare ſight. Moreover, he ſaith, that it troubleth the braines, and putteth folke beſides their wits: that it bringeth the Lithargie upon as many as uſe it, and breedeth oppilations and diſeaſes in the liver. In which regard he ſaith, That Goats by a ſecret in Nature doe refuſe and eſchew it; concluding thereupon, that men alſo ſhould take heed thereof and avoid it. Some there be who have not done with it ſo: but adde moreover and ſay, That if Baſil be ſtam-

A ſtamped and put under a ſtone, it will breed to a Serpent: if it be chewed in ones mouth and laid abroad in the Sunne, it will engender woormes and maggots. The people of Affricke are verely perſuaded, and ſo they give out, That if one be ſtung with a Scorpion, the ſame day that he hath eaten Baſill, it is unpoſſible for to eſcape with life. Likewiſe, ſome hold opinion and would beare us in hand, That if a man ſtampe a bunch or handfull of Baſill, together with ten ſea-crabs, or, as many craifiſhes of the freſh water; all the Scorpions therabout will meet and gather together about that bait. Finally, *Diodorus* in his Empirickes or booke of approved receits and medicines, ſaith, That the eating of Baſill engendreth lice. Contrariwiſe, the later writers and modern Phyſicians defend and maintain the uſe of Baſill as ſtoutly as the other blamed it: for firſt they avouch conſtantly, That Goats uſe to feed therupon. Secondly, that no man was ever knowne to goe be-
B ſides himſelfe, who did eat thereof. Thirdly, that Baſill taken in wine, with a little vinegre put thereto, cureth as well the ſting of land Scorpions, as the venome of thoſe in the ſea. Moreover they affirme upon their knowledge by experience, That a perfume made of Baſill and Vinegre, is ſingular good to recover and fetch them againe that bee gone in a ſwound. Alſo, that in the ſame manner prepared, it rouſeth and wakeneth thoſe who be in a Lethargie and ſleepe continually: yea, and mightily cooleth and refreſheth them that be enflamed and in a burning heat. A liniment made with Baſill, oile Roſate, or oile of Myrtles in ſtead thereof, with vinegre, aſſuageth the paine of the head. Moreover, being laid to the eies with wine, it ſtaieth the wateriſh rheume that runneth thither. Furthermore, comfortable it is to the Stomacke (as they ſay) for being taken with vinegre, it diſſolveth ventoſities, and breaketh wind by rifting upward. Being ap-
C plied outwardly, it bindeth and ſtaieth the running out or flux of the bellie, and yet it cauſeth free paſſage of urine in abundance. After the ſame maner it doth good in caſe of launiſe & Dropſie. It repreſſeth the rage of choler that moveth both upward and downward, yea, and ſtaieth all defluxions from the ſtomacke. And therefore *Philiſtio* knew what hee did well ynough, when hee gave it to thoſe that were troubled with the Stomachicall Flux. As alſo *Pliſtonicus* was well adviſed in miniſtring it ſodden, for the bloudie Flix, the exulceration of the Guts, and the Collicke. Some there he who give it in wine to them who run ever and anone to the cloſe ſtoole, ſit downe and doe nothing: to thoſe that reach and caſt up bloud: yea, and to mollifie the hardneſſe of the precordiall parts. Being laid as a liniment to the nources paps, it reſtraineth the abundance of milke, yea, and drieth it up. There is not a better thing in the world for to bee dropped into the
D eares of little babes and ſucking children, and namely, with Gooſe greaſe. If the ſeed be bruſed, and ſo ſnuffed or drawne up at the noſthrils, it provoketh ſneeſing. The juice moreover laid as a liniment to the forehead, openeth the paſſages, that the rheumes or cold which lay in the head, may breake away. Being taken at meat, and dipped in vinegre, it mundifieth the Matrice and naturall parts of women. Mixed with Copperoſe or Vitrioll, it taketh away werts. Finally, it ſetteth folke forward to venerious pleaſure: which is the reaſon that men uſe to lay Baſill upon the ſhap of Mares or ſhee Aſſes, at the time of their covering.

Chap. xiii.

Of *wild Baſill, Rocket, Creſſes, and Rue.

*Olymoeides, Dioſcor.

E

Wild Baſill is endued with vertues and qualities ſerving to all the purpoſes aboveſaid: but the ſame is of better operation and more effectuall. And theſe properties over and beſides it hath by it ſelfe, namely, To cure the weakneſſe of the ſtomack, and thoſe accidents which come by often caſting or immoderat vomits. The root thereof taken in wine, is ſingular good for the Apoſtumes of the Matrice, and againſt the biting of venomous beaſts.

As touching Rocket, the ſeed cureth as well the venomous ſting of Scorpions, as the biting of the hardie ſhrew. The ſame chaſeth all vermine that be apt to engender in mans bodie. A liniment made therewith, and Honnie together, taketh away all the ſpots that blemiſh the skin of the face: and with vinegre, repreſſeth the red pimples whatſoever. The blacke or ſwert skars re-
F maining after wound or ſore, it reduceth to the former faire white, if it bee applied with a beaſts gall. It is ſaid moreover, that a potion thereof made with wine, and given to thoſe who are to receive puniſhment by the whip, will harden them in ſuch ſort, that they ſhall feele little or no ſmart at all by any ſcourging. And for ſeaſoning of all kind of viands, it hath ſuch a pleaſant grace in any ſauce, that the Greeks thereupon have given it the name of Euzomos. It is thought

more-

moreover, that a fomentation of Rocket, bruſed and ſtamped ſomewhat before, quickeneth and G
clarifieth the eie-ſight: it eaſeth little children of the Chincough. The root boiled in water and ſo applied, draweth forth ſpils of broken bones. As touching the vertue that Rocket hath to procure the heat of luſt, I have ſpoken alreadie: yet thus much more in particular I have to ſay, that if one do gather three leaves of wild Rocket with his left hand, ſtamp them afterwards, & ſo give them to drinke in honied water, this drinke mightily provoketh that way.

As for Creſſes, they have a contrarie operation: for they coole and dull the heat of the fleſh, howſoever otherwiſe they give an edge to the wit and underſtanding, as heretofore wee have declared. Of theſe Creſſes there be two kinds. The white is purgative, and the *weight of *℥ pondere.
a Romane denier taken in water, doth evacuate chollericke humors. A liniment thereof, toge-
ther with Beane flower applied unto the hard kernils called the Kings evill, is a ſoveraigne reme- H
die therefore, ſo that a Colewort leafe be laid thereupon. The other kind is more blackiſh, and purgeth the head of ill humors. It cleanſeth the eies and cleareth the ſight. Taken in vinegre, it ſtaieth their braines that be troubled in mind: and drunke in wine, or eaten with a fig, it is ſingular good for the ſplene. If a man take it faſting every morning with Honey, it cureth the Cough. The ſeed drunke in wine, expelleth all the wormes in the guts: which it doth more effectually, if wild Mints bee joined withall. With Origanum and ſweet wine, it helpeth thoſe that bee ſhort winded and troubled with the Cough. The decoction thereof when it is ſodden in Goats milke, eaſeth the paines of the cheſt or breaſt. Laid too as a Cerot with pitch, it reſolveth puſhes and biles, yea, and draweth forth prickes and thornes out of the bodie. A liniment applied with vinegre, taketh off all ſpots and ſpeckles of the viſage: and if the white of an eggebee put thereto, it I
cureth cankerous ſores. Alſo, beeing applied in forme of a ſoft unguent to the ſpleene, it cureth the infirmities thereof: but if they be little infants that are troubled therewith, there muſt be honey alſo put thereto: and then is it excellent good. *Sextius* addeth moreover and ſaith, That a perfume thereof burnt, driveth away Serpents, and reſiſteth the poiſon of Scorpions: as alſo that being bruiſed and applied with Senvie, it is a ſingular remedie for the head-ach & to make haire grow againe where it was fallen off: alſo, beeing ſtamped into a cataplaſme with a fig, and laid to the eares, it cureth the hardneſſe of hearing. Likewiſe, if the juice thereof be infuſed or poured into the eares, it eaſeth the tooth-ach. Moreover, a liniment made therewith & Gooſe greaſe, ſcoureth away the ſkales and dandruffe, as alſo the ſkalls of the head. A cataplaſme made of it, and levain, ripeneth fellons; bringeth carbuncles to ſuppuration, and breaketh them. With Honey, it K
mundifieth filthie corroſive and cankerous ulcers that eat deepe into the fleſh. A liniment thereof with Barley grotes and vinegre is good for the Sciatica and the paines of the loins: in like maner it cureth Ringwormes and Tettars: it mundifieth the roughneſſe about the nailes, for it is of a cauſtike nature. The beſt Creſſes are the Babylonian. And yet the wild are more effectuall than it, in all caſes abovenamed.

But Rue is an hearbe as medicinable as the beſt. That of the garden hath a broader leafe, and brauncheth more than the wild, which is more hote, vehement and rigorous in all operations. There is a juice uſually preſſed out of it, beeing firſt ſtamped and ſprinckled a little with water in the ſtamping, and then put up into a boxe of copper or braſſe, and there reſerved for to be uſed as occaſion ſerveth: This juice taken in a great quantitie, is a very poyſon and no bet- L
ter; eſpecially that which is drawne out of the Rue which groweth in Macedonie about the river Aliacmon. But will you heare a ſtraunge and wonderfull thing? the juice of Hemlocke killeth this venomous qualitie of it. See how one poyſon is a counter-poyſon to another: inſomuch, as if they annoint their hands with the juice of Hemlocke, who are to gather Rue, they ſhall not be envenomed therewith. And yet as venomous otherwiſe as Rue is, it goeth into the compoſition of thoſe Antidots which are given againſt poyſon, eſpecially that Rue of Galatia. And to ſpeake in generall, there are none of theſe Rues, but the leaves both bruiſed alone & alſo taken in wine, ſerve for preſervatives: & principally, againſt the hearbe Aconite or Libard-bane, & the viſcous gom of the hearbe Chamelæon, which they call Ixias: likewiſe againſt deadly and venomous Muſhromes taken at the mouth, whether it bee by way of meat or drinke. In like man- M
ner it is ſingular good againſt the ſtinging of Serpents: for the very Weaſels when they prepare themſelves to combat with them, uſe to eat this hearbe beforehand, for to bee ſecured from their venome. Availeable it is alſo againſt the pricks of Scorpions and Hardi-ſhrews, againſt the ſtings of Bees, Hornets, and Waſps, againſt the poiſon of the Cantharides & Salamanders, yea & the

biting

A biting of a mad dog; if it be uſed in this wiſe, namely, to take a ſaucer full or acetable of the juice, and ſo to drinke it with wine: alſo to ſtampe or but champe in the mouth the leaves thereof, and ſo lay them upon the greeved place with honey and ſalt; or elſe to ſeeth them with vinegre and pitch. Folke ſay moreover, that whoſoever is well rubbed with the juice of Rue, or otherwiſe doe but carie it about him, ſhall be ſure ynough for being either pricked, ſtung, or bitten with any of thoſe hurtfull and venomous creatures abovenamed: furthermore, that Serpents naturally doe flie from the ſmoke or fume of Rue when it burneth, and will not come near unto it. But the moſt ſoveraigne of all other, and ſureſt in operation, is the root of the wild Rue, if it bee drunke with wine. And the common ſpeech goeth of it, that the greater and ſpeedier effect will bee ſeene, in caſe forſooth one drinke it without the houſe, in the open aire abroad. *Pythagoras* was of opini-
B nion, That there is a diſtinction of ſex in this hearbe, and namely, that the male hath ſmaller leaves, and thoſe of a more darke and graſſe green colour than the female, whoſe leaves are both fuller and better fed, and alſo of a more pleaſant and gaier hew. Hee was perſuaded alſo that Rue is hurtfull to the eies, but therein he was deceived. For well it is knowne, that engravers, carvers, and painters, doe ordinarily eat Rue alone for to preſerve their eie-ſight: they take it alſo with bread or Creſſes, without any regard whether it be the wild or the gentle Rue of the garden. By report alſo, many have uſed an inunction thereof to their eies, with the beſt honie of Athens, and thereby cleared them quite of that muddineſſe and miſt which dimmed their ſight: or elſe in ſtead of honey they have taken breaſt-milke of a woman that lately bare a maiden child; or no more but with the very pure juice of Rue and nothing els they have gently touched the corners
C of the eies. Others have cured the waterie humor that hath taken a running thither, only by applying the juice of Rue together with Barley groats. If a man drinke Rue with his wine, hee ſhall find eaſe of his head-ach: or if hee doe but annoint his temples and forehead therewith, being incorporat with vinegre and oile of Roſes into the forme of a liniment. But if it bee an old and inveterat paine of the head, then would there a frontale be made of the ſaid juice, tempered with Barley floure and vinegre. Rue hath this vertue, to diſcuſſe and reſolve all crudities and ventoſities proceeding thereof, yea, and cureth the ſettled old paines of the ſtomacke. It is of power to diſopilate or open the Matrice: to ſettle the Mother into the right place when it is looſe & out of frame, in caſe a liniment be made thereof, and laid all over the region both of the womb and the breaſt. If Rue be eaten with figs, or ſodden to the conſumption of the one halfe-deale, and the
D decoction thereof taken in wine, it is good for the Dropſie. And in that manner they uſe to drink it for the paines of the breaſt, ſides, and loines: for Coughs alſo and ſhortneſſe of breath, & generally for all greefes and maladies incident to the lights, liver, and kidneies: and laſt of all, for the ſhaking cold fits in an intermittent ague. Is a man diſpoſed to drinke freely, and to ſit ſquare at it? let him before hee begin take a draught of the decoction of Rue leaves, hee ſhall beare his drinke well, and withſtand the fumes that might trouble and intoxicat his brains. In one word, uſed ordinarily at meat, either raw, ſodden, or preſerved and condite any way, it is ſingular good for the purpoſes beforeſaid. Boiled with Hyſſope and taken in wine, it is ſingular for to aſſuage the torments of the bellie: and being ſo prepared, it reſtraineth the flux of bloud within the bodie: like as it ſtancheth bleeding at the noſe, if it be ſtamped and put up into the noſethrils. And
E otherwiſe a collution thereof to waſh the mouth withall, doth much good to the teeth. Semblably, the juice diſtilled into the eares, allaieth their paine; provided alwaies (as I have often ſaid alreadie) that a meane and meaſure be kept. As for the juice of the wild Rue, if it bee tempered either with oile of Roſes or of Baies; or elſe mingled with Cumin and Honnie, it helpeth thoſe that are hard of hearing, and diſcuſſeth the ringing ſound in the eares. Moreover, the juice of Rue ſtamped and drawne with vinegre, is excellent good to be inſtilled or let drop from on high by way of Embrochation upon the region of the braine and temples of the head, for the phrenſie. Some put thereto wild running Thime alſo and Baies, therewith annointing the head & neck of the patient. Others have preſcribed it in caſe of Lethargie to thoſe that can do no other but ſleep continually, for to ſmell unto. And thoſe have given counſell alſo to them that be ſubject to the
F falling ſickneſſe, for to drinke the juice thereof ſodden in foure Cyaths of water, before the fit came upon them; for to prevent & avoid the intollerable cold which they ſhould endure: as alſo to thoſe that be apt to *chill for cold, to be eaten with meat, raw. Rue ſendeth out even the bloudie urine which is gathered in the bladder. And as *Hippocrates* is of opinion, If it be drunke with ſweet, thicke, and groſſe wine, it cauſeth womens flowers to come downe, it expelleth the after-birth,

* *Alſioſis*. Some read *Alphioſis*, [out of *Dioſcorides*] that is, to them that are ſubject to the white Morphew, which is a kind of Leproſie, or S. *Magnus* evill.

birth,yea,and the dead infant within the wombe. And therefore he adviſeth women in travell to have thoſe naturall parts annointed with Rue,yea,& to ſit over a ſuffumigation made thereof. *Diocles* maketh a cataplaſme with Rue,Vinegre,Honie,and Barley flower,for faintings,cold ſweats, and tremblings of the heart. Likewiſe,againſt the torments of the ſmall guts,commonly called the *Iliake paſſion, he appointeth to take the decoction thereof in Oile, and to receive the ſame in lockes of wooll,and ſo to be applied unto the upper region of the bellie. Many doe ſet downe two drams thereof drie,and one dram and a halfe of Brimſtone, as an excellent receit to bee taken by thoſe that reach and ſpit up filthie and ſtinking matter: but if they caſt or ſend up bloud, they ſhould drinke the decoction of three braunches thereof in wine. It is an ordinarie practiſe in caſe of the Dyſenterie or bloudie Flix, to give it ſtamped firſt with cheeſe, in wine: but they mingle therewith Bitumen,and ſo crum or breake it in to their drink,againſt the difficultie of taking wine. Alſo three drams of the ſeed thereof is given in drinke to thoſe that are fallen from a loft,for to diſſolve the bruiſed and cluttered bloud within them. *Item*, Take one pound or pint of oile,of wine one ſextar or wine quart,ſeeth the leaves of Rue herein: that oile ſo prepared,is ſingular good for to annoint the parts which are benummed, and in manner mortified and blacke with cold. Moreover,conſidering that it is Diuretical,as *Hippocrates* thinketh,and doth provoke urine;I cannot but wonder at ſome,who give it as a thing that ſtaieth urine, & therfore appoint it to bee drunke by thoſe that cannot hold their water. The inunction thereof with Allum and Honie,cleanſeth the drie wild ſcab & leproſie. Likewiſe with Morell or Nightſhade,Hogs greaſe and Buls tallow,it ſcoureth the Morphew,taketh away werts,diſcuſſeth and diſpatcheth the Kings evill and ſuch like tumors. In like manner it killeth the fretting hote humor called S. *Anthonies* fire,being applied to the place with Vinegre, Honnie,or Ceruſſe,*i.* white Lead: like as it cureth the Carbuncle laid too,with Vinegre alone. Some there be who preſcribe Laſerpitium alſo to be joined with the reſt in this liniment: but without it they cure the chilblanes and bloudie fals that bee ſo angrie in the night ſeaſon. Many uſe to boile Rue,and together with wax,reduce it into a Cerot; which they applie unto the ſwollen breaſts or paps of women,as alſo to the breaking out of phlegmaticke puſtules or whealks[much like to our meaſels or ſmall pockes.]Alſo beeing reduced into an unguent with the tender ſprigs or tops of Laurell,it is a ſingular remedie for the Flux or fall of humors into the burſe of the cods. And verely this Rue is counted ſo excellent an hearbe in operation this waies,& ſo reſpective peculiarly to thoſe parts,that it is commonly holden for a ſoveraigne remedie to heale all ruptures; if a man take the wild of that kind and make a liniment of it and old Swines greaſe together. Likewiſe,if any bones or lims bee broken, a Cerot made with the ſeed of Rue and wax together,is able to ſouder the fracture. The root of Rue being reduced into a liniment,cureth bloudſhotten eies,and reſtoreth to the native colour all ſcars or ſpots that give blemiſh to any part of the bodie. Among the other properties that be reported of Rue,this is one to be wondered at,conſidering how hot it is of nature(as all Phyſicians do agree) That a bunch thereof being boiled in oile Roſate,and with one ounce of Aloe brought into the forme of an ointment,ſhould repreſſe their ſivet,who are annointed therewith. As alſo, that the ordinarie uſe thereof at meat ſhould diſable folke as well in the act of generation, as conception: In which regard is it preſcribed unto them that ſhed their ſeed,and unto ſuch as uſe to dreame in their ſleepe of amatorious matters and the delights of *Venus*. But women with child muſt beware how they eat Rue: they eſpecially muſt forbear this hearb: for I find that it killeth the yong child conceived within their bodies. Thus much for the effects that it worketh in men & women. Over and beſides all which, there is not an hearbe growing in the garden that is ſo much uſed for the curing of foure footed beaſts, whether it bee that they bee broken winded and purſive,or otherwiſe bitten and ſtung with venomous beaſts; in which caſes, there muſt be an injection made up into the noſthrils,of the juice of Rue in wine. Alſo,if it chaunce that a beaſt hath ſwallowed an Horſeleech in drinking,let it be taken with vinegre. Finally,in every accident of theirs,let Rue be prepared and miniſtred reſpectively unto each griefe,according to the manner ſet down for men in the ſemblable caſe.

*or, *Domine miſerere mei, i.* Lord have mercie upon me.

Chap. xiiii.

Of wild Mint: of garden Mint: of Penyroiall: of Nep, and Cumin.

WIld Mint is called in Latin Mentaſtrum: it differeth from the other in the forme of the leaves: *for ſhaped it is like Baſill, howſoever in colour it reſembleth Penyroiall,which is

*All this agreeth to our Calaminth: according to *Dioſcorides.*

A is the cauſe, that ſome name it the ſavage Penyroiall. In the time of *Pompey* the Great, it was knowne by experience, that the leaves of wild Mint chewed and applied outwardly, cured the Leproſie: by occaſion, that a certaine leaper minding to diſguiſe himſelfe, that hee might not for very ſhame bee knowne, chaunced to annoint and beſmeare his face all over with the juice of wild Mints. But fortune was better miſtriſſe unto him than he expected, for beyond his expectation or intent, his good hap was to be rid of his Leproſie by that meanes. The ſame leaves ſerve for a liniment againſt the venome of Scolopendres, and the ſting of Serpents: ſo doe they alſo, if one drinke two drams of the leaves in two Cyaths of wine. Alſo, for to cure the prickes of Scorpions, they be uſed with ſalt, oile, and vinegre. But againſt Scolopendres, commonly they drinke the juice or broth of the decoction. Moreover, the wiſer ſort of people ſave the drie
B leaves of wild Mints to bee reduced into a pouder, as a very counterpoyſon againſt all venome whatſoever. For being ſtrewed in the houſe, or burnt, the very aire and perfume thereof chaſeth away Scorpions. A drinke made therwith purgeth and purifieth women paſſing well, ſuch I mean as be newly delivered of childbirth; but it killeth the fruit within the wombe of as many as uſe it while they goe with child. There is not a medicine in the world ſo effectuall as it is for thoſe, who are ſo ſtreight winded, that they cannot take their breath unleſſe they ſit upright: for ſuch alſo as in the chollerick paſſion, never give over caſting upward & purging downward. It appeaſeth alſo the paine of the loines, and eaſeth the gout, if it be applied to the place affected. The juice thereof is good to be dropped into eares that have wormes within them. It is uſually taken in drink for the Iauniſe. A liniment made therof, helpeth the kings evill: beſides, it is a ſingular remedie for
C them that by a ſtrong imagination of *Venus* in their dreames, defile and pollute themſelves in their ſleepe. If one drinke it with vinegre, it excludeth the flat broad wormes in the bellie. To ſcoure away the foule dandruffe, an Embrochation of it and vinegre upon the head in the Sun is counted ſingular.

As touching garden Mint, as the very ſmell of it alone recovereth and refreſheth the ſpirits: ſo the taſt ſtirreth up the appetite to meat, which is the cauſe, that it is ſo ordinarie in our ſharpe ſauces wherein we uſe to dip our meats. Being put into milke, it will not ſuffer it to turn or ſoure, it keepeth it from quailing & curding: which is the reaſon, that they who uſe ordinarily to drinke milke, take Mints therewith, for feare it ſhould coagulate or crudle in their ſtomacke, & put them
D in daunger of ſuffocation. Some, for the ſame effect uſe to give it in water or honied wine: and ſurely it is thought by that very propertie to hinder generation, in that it diſſolveth the due conſiſtence and thickneſſe which is required in naturall ſeed. And yet it is a great ſtancher of bloud indifferently in men and women: but more particularly it ſtaieth the immoderat flux of whites * ῥοὴν γυναικεῖον. that many times followeth women. Being taken with Amydum or ſtanch-pouder in water, it reſtraineth the inordinat flux occaſioned by the imbecilitie of the ſtomacke. *Syriation* the Phyſician uſed ordinarily to cure the apoſtumes and ſores of the Matrice, with Mint. Alſo againſt the obſtructions & other accidents of the liver, he was wont to give three Oboles therof in honied wine. And for them that raught up bloud at the mouth, he preſcribed to take Mints in a broth or ſupping. The skall that little children be troubled withall, it healeth wonderfull well. It is ſingular to drie up the humors that mollifie the griſtly wind pipe & the other inſtruments of the breath and
E voice; and when they are drie, knitteth and ſtrengtheneth them. Taken in water and honied wine, it cleanſeth the corrupt and putrified flegmaticke humors which bee offenſive to the throat and thoſe parts. The juice of Mints is excellent for to ſcoure the pipes and clear the voice, being drunk a little before that a man is to ſtraine himſelfe, either in the quier, or upon the ſtage, or at the bar; and not otherwiſe. A gargariſme of milke, wherin hath ben Rue and Coriander, beſides Mints, is paſſing good to bring down the ſwelling of the Vvula. Being uſed in that manner with ſome Allum, it reſtraineth the mumps or inflammation of the Amygdales: and with Honie it cureth the roughnes & furring of the toung. Being uſed alone without any other addition, it is a proper medicine for inward convulſions, as alſo for the diſeaſe of the lungs. *Democritus* ſaith, that to drinke it with the juice of a Pomgranat, is a ready means to ſtay the yex and vomiting. The juice of green
F Mints, drawn up with the wind into the noſthrils, helpeth the ſtinking ulcers there. The hearb it ſelfe ſtamped, repreſſeth the rage of choler that purgeth both waies unceſſantly, but it muſt bee drunke with vinegre. And in that manner it reſtraineth all internall fluxions of bloud. But applied outwardly with Barly groats to the grieved place, it eaſeth the intollerable pain of the Iliake paſſion: after the ſame ſort if it be ſpread and emplaiſtered, it allaieth the ſwelling of womens breaſts.

In

In caſe of headach, a liniment thereof doth well to be applied unto the temples. Inwardly it is ta- G
ken with very good effect againſt the venomous Scolopendres, the ſea Scorpions, and other ſer-
pents. A liniment thereof ſtayeth the wateriſh humors that have taken a courſe to the eyes, cu-
reth the skalls and breakings out of the head, and all accidents offenſive to the tiwill or funda-
ment. If one doe but hold Mints in his hand, hee ſhall not need to feare either chauſing or gal-
ling in any part, upon travaile. Being dropped into the eares with honied wine, it is very comfor-
table to that part. It is ſaid moreover, that if a man come into a garden where Mints groweth,
and bite the leaves upon the very plant, without plucking or cropping it off, and continue this
courſe nine daies togither, iterating evermore theſe words [*I doe this to cure the ſplene*] hee ſhall
find remedy indeed for the infirmitie of that part. Moreover, let one take as much poudred mints
dried as hee can well containe with his three fingers ends, and drinke the ſame with water, it will H
cure the head-ach, or grievous paine of the ſtomack. Likewiſe if his drinke be ſpiced with the ſaid
powder, it will drive out of the belly the worms there engendred.

The braunches of Mint and Penyroiall both, are uſually put into glaſſe viols with vinegre, for to be infuſed therein: and a man would not thinke how good this vinegre is for faintings of the heart; ſo great is the ſocietie that theſe two hearbs have one with the other in this behalfe. For which cauſe, I remember upon a time when divers learned Phyſicians were met togither to con-
fer in my chamber, they reſolved & concluded definitly, That a chapler of Penyroiall was with-
out compariſon far better for the giddineſſe and ſwimming of the head, than one of roſes; for a
garland of Penyroiall, if it be worne onely upon the head, allayeth (by report) the ach thereof.
More than that, it is ſaid, That the very ſent of Penyroiall preſerveth the brain from the offence I
that may come by the diſtemperature either of heat or cold, yea and from the inconvenience
of thirſtineſſe: inſomuch as whoſoever have two braunches or ſprigs of Penyroiall put into his
ears, ſhall feele no exceſſive heat though they continued in the Sun all the day long. Penyroiall
being applied in forme of a liniment, togither with barley groats and vinegre, aſſuageth all grie-
vous paines whatſoever. Howbeit, the female of this kind is thought to be of greater operation
every way, than the male. Now hath this female a purple floure, that you may know it thereby
from the other; for that of the male is white. The female Penyroiall taken in a maſh made with
ſalt and barley groats in cold water, ſtaieth a keckliſh ſtomacke, and keepeth it from the inordi-
nat deſire and many offers to caſt. In the ſame manner alſo it eaſeth the paine of the breaſt and
belly. Likewiſe the gnawings of the ſtomacke it ceaſeth, being taken in water; as alſo immoderat K
vomits it repreſſeth, with vinegre and barley groats. Beeing ſodden in honey with a little nitre
among, it cureth the maladies of the guts. If one drinke it with wine, it cauſeth abundance of
urine: and if the ſaid wine be made of the Amminean grapes, it expelleth the ſtone and gravell,
yea and all things els which may engender inward paines. If it be taken with honey and vinegre,
it provoketh womens tearmes, and quieteth them when they lye gnawing and fretting inwardly,
yea and ſendeth foorth the after-burden. The ſame ſetleth the mother and reduceth it into the
right place. It expelleth alſo the dead child within the mothers bodie. The ſeed of Penyroiall if
it be ſmelled unto, is ſingular good to recover their tongue againe who be ſpeechleſſe: for the
falling ſickneſſe alſo, it is given in a cyath of vinegre. If it fortune that one muſt drinke unhole-
ſome waters, the ſeed thereof reduced into powder and ſtrewed thereupon, correcteth all the L
malice thereof. If the ſame be taken in wine, it ſlaketh the itch in the bodie proceeding of hot
and ſalt humors. The ſeed of Penyroiall, mingled with ſalt, vinegre, and honey, if it be well rub-
bed into the bodie, comforteth the ſinewes in caſe of cramps and convulſions: and particularly
helpeth thoſe who with a cricke are forced to carrie their necke much backward. The decoction
thereof is a ſoveraigne drinke againſt the ſting of Serpents; and particularly of Scorpions, if it
be bruiſed and taken with wine: eſpecially that which groweth in drie places. Moreover, Peny-
royall is held to bee very ſoveraigne for the cankers or ulcers in the mouth: and as effectuall to
ſtay the cough. The floures of Penyroiall that be freſh and new gathered, if they be burnt make
a ſingular perfume to kill fleas. Among many good receits that *Xenocrates* hath left unto us, wee
find this for one, namely, That a braunch of Penyroiall wrapped within wooll, and given to the M
Patient for to ſmell unto before the fit come of a tertian ague, driveth it away: as alſo if it be put
under the coverlet of the bed, and the Patient laid upon it, it doth no leſſe. For theſe purpoſes
above named, the wild Penyroiall is of moſt efficacie: This hearb reſembleth Origan, and hath
ſmaller leaves than the Penyroiall of the Garden: ſome give it the name of Dictamnus. If it

chaunce

A chaunce that either ſheepe or goats doe taſt thereof, it provoketh them preſently to blea: wherupon certaine author, chaunging one letter for another in Greeke, call it * βλήχων. This hearb is ſo hot and ardent, that if any part of the bodie be rubbed or annointed therewith, it will riſe into a bliſter. If one have taken a through cold and thereby gotten a cough, Phyſicians have preſcribed to uſe frictions therewith, before the Patient goe into the baine for to ſweat. Alſo their direction is to do the like before the cold fits of agues; as alſo in caſe of the cramp and torments of the guts. Wonderfull good it is in all kinds of gout. If it bee taken in drinke with honey and ſalt, it is ſingular for thoſe who bee diſeaſed in the liver, as alſo for the lights; for it openeth their pipes and diſchargeth them of the fleam that ſtuffed them, ſo as they may reach up and void the ſame with eaſe. The decoction thereof, with ſome ſalt, is excellent good for the ſplene and the
B bladder; yea and for all ventoſities and ſhortneſſe of breath. Semblably, the juice prepared and dreſſed in manner aforeſaid, bringeth the mother into the naturall place; and ſerveth as a countrepoiſon againſt the Sconlopendre both of the ſea and the land: as alſo for the pricke of Scorpion: and eſpecially againſt the biting of man or woman. The root thereof being applied freſh and greene, is marvellous good to repreſſe ranke ulcers, and to conſume the proud fleſh about them. The ſame being drie and ſo applied, reduceth skars to their freſh colour and beautie of the faire and whole skin. Thus much of Penyroiall of the garden and the field.

* For βλήχωι.

Great conformitie there is in operation betweene Penyroiall and * Nep: for being both of them boiled in water unto the conſumption of a third part, they diſcuſſe and ſhake off the cold in ague fits which cauſeth the Patient to ſhake; and beſides, are of validitie to bring downe wo-
C mens monethly ſickneſſe. In Summer time, they aſſuage the extremitie of heat. Nep alſo is powerfull againſt Serpents, for the ſmoke and perfume of this hearb they cannot abide, but will flie from it: which is the cauſe that ſuch as bee afraid of Serpents, ſtrew Nep under them in the place where they meane to repoſe and ſleepe. Being bruſed and applied to the running fiſtulous ulcers betweene the noſe and the greater corner of the eye, it is counted a ſoveraigne remedie: alſo being freſh gathered, and mixed with a third part of bread, and ſo tempered and incorporat with vinegre to the forme of a liniment, it cureth the head-ach. The juice thereof being inſtilled into the noſthrils, whiles the Patient lyeth upon his backe, ſtancheth bleeding at the noſe. The root alſo, togither with Myrtle ſeed, in warme wine cuit & ſo gargarized, helpeth the Squi-
D nancie. As touching wild Cumin, it is an hearb exceeding ſmall, putting foorth foure or five leaves and not above, and thoſe indented like a Saw: But the garden Cumin is of ſingular uſe in Phyſicke, but principally for the paine in the ſtomacke. It diſpatcheth the groſſe vapours ariſing from fleame; it diſſolveth alſo ventoſities, if it bee either bruiſed and eaten with bread, or drunke with water and wine: in which ſort it aſſuageth the wringing torments and other paines of the guts: howbeit, it maketh folke looke pale as many as drinke of it. Certes by that deviſe, namely, by ordinarie drinking of Cumin (as it is reported) the ſchollers and followers of *Portius Latro* (that famous and great Rhetorician) procured themſelves pale faces becauſe they would look like their maſter; who in deed came to that colour by continuall ſtudie & plying his booke. Thus likewiſe not long ſince, *Iulius Vindex*, being deſirous to be affraunchiſed by *Nero*, pretending by his pale viſage and poore look, that he had not many daies to live, made faire ſemblance
E unto *Nero* by his will and teſtament, that he ſhould ſhortly bee his heire; (which cheat the ſaid *Nero* gaped after;) and ſo by that means *Vindex* entred ſo far within him, as he obtained whatſoever he would at his hands. Cumin reduced into the forme of throchiskes or * noſe-tents put up into the noſthrils, ſtaunceth bloud. The like effect it hath, being freſh gathered and applied with vinegre. Being laid it ſelfe alone, to watering and weeping eyes, it reſtraineth that humor: and in caſe the cods bee bolne or ſwelled, it is good to mix honey withall in manner of an emplaſter: But it ſufficeth to make a cataplaſme therof, and lay it to the belly alone, of little babes and infants that way troubled. Finally, to cure the jauniſe it is ſingular, given in white wine when the Patient hath ſwet and is come out of the baine.

* called *Errhina* or *Naſcalia*.

F

Chap. xv.

☞ * *Of Cumin Æthiopicke, which reſtraineth the flix of urine: of Capres: of Lovach or Panax: and of a kind of Marjerom named Cunila-bubula.*

* It ſeemeth that this Title is corrupt.

BVt for the purpoſe aforeſaid, namely to cure the jaundiſe, the Æthiopian Cumin is the beſt, being taken after a bath with vinegre and water: alſo licked in manner of a Loch with hony.

As for the Cumin of Africke, it is thought to have a ſingular proprietie by it ſelfe for to help thoſe who cannot contain & hold their urine. The garden Cumin, if it be parched dry, brought into powder, and given in vinegre, helpeth the defects and infirmities of the liver. Alſo it cureth the dizzineſſe of the head. But in caſe the acrimonie or ſharpneſſe of the urine be ſuch, as that it fret and moove ſmart in the paſſage, the powder thereof would bee tempered in ſweet * wine cuit. For the impediments of the matrice, it ought to be drunke in pure wine of the grape: and withall, there muſt be applied to the part offended, a cataplaſme of the leaves upon a locke of wooll. Dried againſt the fire, bruiſed and beaten into powder, and ſo incorporat with oile of roſes and wax, and wrought in the end to the forme of a cerot, and then applied, it abateth the ſwelling of the cods. But the wild Cumin is more effectuall in all the caſes above mentioned, than that of the garden. Over and beſides, it hath a ſpeciall vertue, togither with oile, againſt Serpents, Scorpions, and Scolopendres. Take as much of Cumin ſeed as you may comprehend within three fingers, drinke it in wine, it will ſtay immoderat vomit, yea and the ſicke heaving of the ſtomacke, as if it would caſt and cannot. A drinke made therewith, is given alſo for the cholique: and to that purpoſe, a liniment thereof is very commendable; or if it bee applied hot in quilted bags, ſo that the ſame be kept ſwadled down unto the region of the gut Colon. For a woman that is given to the riſing and ſuffocation of the mother, let her drinke it in wine after this proportion, Three drams of Cumin to three cyaths of wine; ſhee ſhall find that it will reſolve thoſe vapours and fumoſities which cauſed the foreſaid maladie. With calves tallow or ſewet, or with honey, if it be let drop into the eares, it cureth the ſounding and tingling therein. Being applied as a liniment with honey, raiſons, and vinegre, it reſolveth the blacke and blew marks remaining after ſtripes. Alſo with vinegre alone, it cureth the blacke ſpots and ſpeckles appearing in any part of the bodie, if the place be bathed therewith.

* *In dulci*: he meaneth *paſſum*.

An herb there is reſembling Cumin for all the world, which the Greeks call Ammi: although ſome there are who thinke it to be all one with the Cumin of Æthiopia. *Hippocrates* calleth it, the Roiall Cumin [of Ægypt;] the reaſon was, no doubt, becauſe he deemed that of Ægypt to exceed all the reſt in goodneſſe. But moſt writers beſides him, do thinke it * an herb altogither of another nature, becauſe it is ſmaller and whiter: and yet it ſerveth to the like uſe; for at Alexandria in Ægypt they put it commonly under their loaves of bread in the bottom cruſt when they go to the oven: and ordinarily it is occupied in the kitchin about ſawces. Be it what it will, it diſſolveth ventoſities, it pacifieth the wringing torment of the guts, it provoketh urine, and bringeth downe womens months. Being taken in wine (togither with Line ſeed) to the quantitie of two drams, it cureth the venomous ſtings of Scorpions: but put thereto an equall quantitie of myrrhe, it hath a ſingular vertue againſt the horned ſerpent Ceraſtes. And, like to the other Cumin before named, it altereth the colour of as many as drink of it, and makes them look pale. A ſuffumigation made thereof, with Raiſons and Roſin, mundifieth the matrice and naturall parts of women. Finally, it is commonly ſaid, That if a woman ſmell thereto, in the very act of generation, ſhe ſhall conceive the rather by that means.

* *Ruellius* taketh it for Baſil gentle.

As for Capres, wee have ſufficiently written thereof among other ſhrubs that be ſtraungers: and yet it will not be amiſſe to reiterat thus much, That a man muſt be well adviſed how he taketh any outlandiſh Capres that come from beyond-ſea: but if hee will goe ſafely to worke, let him hardly keepe him to thoſe of Italy, for they are leſſe harmeleſſe than the other: for if all bee true that is commonly reported, whoſoever daily eat Capres, ſhall not be in daunger either of palſie or pain of ſplene. The root of Capers is ſingular good to take away the white ſpotted morphew, (couſin germane to the leproſie) in caſe it be ſtamped, and the place affected rubbed therewith. Take the rind of the root, the quantitie of two drams, and drinke it in wine, it helpeth the ſwelled ſplene; provided alwaies, that the Patient forbeare the uſe of baines and hot-houſes: for (by report) this courſe continued 35 daies, will cauſe the ſaid ſplene to purge away, partly by urine and partly by ſeege. The ſame, if it be taken in drinke, allaieth paine in the loins and cureth the palſey. The ſeed of Capres ſodden in vinegre, bruſed and applied to the teeth, or otherwiſe the root thereof chewed only, aſſuageth the tooth-ach. A decoction of Capres in oile, inſtilled into the ears, mitigateth their paines. The leaves and the root newly gathered, and ſo applied as a cataplaſme with honey, healeth the corroſive ulcers that eat to the very bone. Likewiſe the root reſolveth all thoſe glandulous ſwellings which wee name the Kings evill: and if the ſame be ſodden in water, it diſcuſſeth the tumors behind the ears, and riddeth away the wormes breeding within.

It

A It cureth alſo the infirmities of the liver. The manner is to give the ſame in vinegre and honey for to chaſe away the vermin engendred within the guts. Boiled in vinegre, it is ſingular for the cankers or exulcerations within the mouth: howbeit, all authors doe accord, that they bee not good for the ſtomacke.

Touching Lovage, which ſome call Panax, it is * holeſome for the ſtomacke. Likewiſe a proper medecine it is for convulſions and ventoſities. To conclude, there are ſome who name it Cunila Bubula, as I have before noted, but they be deceived.

* *Vtile: nam concoctionem iuvat. Ex* Dioſcor.

Chap. XVI.

Of the wild Origan Cunila Bubula: of the Baſtard Marjoram, named Gallinacea Cunila, or Heracleoticum Origanum: of the tender Cunilago: of Roſemarie: of Garden Savorie or Cunila, and that of the mountains.

B OVer and beſides the Garden Savorie, there be many kinds of Cunila known in Phyſicke: and firſt, that which is called Bubula, & hath ſeed like unto Penyroiall, being either chewed in the mouth or applied outwardly, it is a good wound-hearb, ſo that it be not remooved but every five daies. Taken in wine, it is ſingular againſt the poiſonous ſting of Serpents, in caſe the hearbe it ſelfe be ſtamped, and laid withall upon the ſore place: and verely it is an ordinarie thing, to rub therewith well and throughly, the wounds that they make. Semblably, the Tortoiſes, againſt the time that they ſhould fight with Serpents, uſe this hearb in manner of a
C defenſative, and take themſelves well armed againſt their enemie: which is the reaſon, that ſome give it the name of Panax. Being dried, it aſſuageth the paine of tumors, & cureth the accidents that befall to the privie members of men: Or if the leaves be but ſtamped, they have the like effect. And in one word, the operation thereof is excellent and wonderfull, if it be uſed in wine.

Another Cunila or Savorie there is, which our countreymen call in Latin Gallinacea; the Greekes name it Origanum Heracleoticum. If it bee brayed and ſalt joyned thereto, it is ſoveraigne for the eyes: it helpeth the cough alſo, and correcteth all faults of the liver. If a thicke grewell or ſew be made thereof, together with floure, oile, and vinegre, ſo tempered as it may be ſupped, it cureth the pleureſie or paines of the ſides: but above all, it is ſingular for the ſtinging of Serpents.

D A third kind there is, which the Greeks tearme the male, but we in Latin * Cunilago: a ſtinking ſmell it hath with it, a woodie hard root, and a rough leafe: but it is generally ſaid, that the operations thereof be more effectuall, than of any other kind. It is verely thought, that if a man caſt an handfull thereof from him into any part of the houſe, all the moths and ſuch like vermin will gather about it. But to come to particulars, It hath a ſingular power againſt Scorpions if it be taken with water and vinegre. Alſo if a man or woman take three leaves thereof, and rub his bodie throughly with it and oile togither, there is not a Serpent ſo hardie as dare approch neare ſuch a bodie ſo perfumed. Contrariwiſe the Cunila, which is named Mollis, [*id eſt*, Soft] hath leaves and braunches more hairie than the former, and thoſe ſharpe pointed like pricks. This hearbe if a man rub betweene his fingers, reſembleth honey in ſmell, and will ſticke faſt to in
E manner of honey. Another ſort there is of Cunila, which we, for the ſmell that it hath of Frankincenſe, call Libanotis. But both theſe, the one as well as the other, taken in wine or vinegre, cureth the biting and ſting of Serpents. If they be bruiſed or ſtamped into powder, and ſo put into water, they kill all the fleas in the place where the ſaid water is caſt or ſprinkled. As for the garden Savorie, it alſo hath many good properties: The juice thereof with oyle of roſes diſtilled into the ears, is very comfortable unto them. The hearbe it ſelfe taken in drinke, helpeth thoſe who are ſtung with venomous Serpents. This Savorie oftentimes doth degenerat into a baſtard kind, named Mountain Savorie. Like it is to wild running Thyme, and is effectuall likewiſe againſt the poiſon of Serpents. It provoketh urine, and purgeth women newly delivered, if haply they have not ſufficient voidance. Singular it is for to help digeſtion, and ſtirreth up appetite to
F meat wonderfully. In ſum, as well the gentle Savorie as the wild, is paſſing holeſome for crudities in the ſtomacke, if one ſpice his morning draught therewith faſting. It is uſed alſo to very good purpoſe in diſlocations and members out of joynt: with barley meale, water, and vinegre, it is excellent for the ſtinging of waſps, and ſuch like pricks. As touching the other kinds of Libanotis or Roſemarie, write I will more fully in due place.

* Flea bane.

G

Chap. xvii.

Of Piperitis and Origanum: of Onitis-Prasium: of Tragoriganum, and Heraclium: of Lepidium and Gith or Melanthium: of Anniſe.

* Ginny pepper.

PIperitis or Calecut Pepper-wort (which before wee called * Siliquaſtrum) beeing taken in drinke, is very good for the falling ſickneſſe. *Caſtor* hath deſcribed it after another manner, namely, to be an hearb riſing up with a long red ſtem, thickeſet with joynts or little knees; bearing leaves reſembling thoſe of Lawrell; with white ſeed and the ſame ſmall, carrying with it the taſt of pepper. The vertues of which hearbe be theſe; To helpe the gumbs and teeth, to make a ſweet breath, and withſtand ſoure and ſtinking belches.

H

* *Cunila.*

Origan or Orgament, which in taſt (as wee have ſaid) reſembleth * Saverie, hath many kinds, and all medicinable: for there is one ſort thereof, ſurnamed Onitis or Praſion, not unlike to hyſſope: a peculiar propertie this hearb hath being drunke in warme water, to quiet the gnawings in the ſtomacke, and to concoct the crudities there: but taken in white wine, to cure the venomous pricks of Spiders and Scorpions. The ſame applied outwardly with oile and vinegre upon wooll, is ſingular good for diſlocations, disjointures, ſpraines, contuſions, and bruiſes.

As for Tragoriganum, it is more like unto wild creeping Thyme: it hath vertue to provoke urine, to diſcuſſe and reſolve all tumors or ſwellings. And more particularly, moſt effectuall it is for them that have drunke the gum of Chamelæon, called Ixia: alſo againſt the Vipers ſting: beſides, for the ſtomacke that belcheth ſowre, and for the midriffe and precordiall parts. It is an approoved medecine for the cough, the phrenſie, and inflammation of the lungs, beeing with honey reduced into the forme of a Lohoch, for to be ſucked downe leiſurely.

I

Touching the Origan named Heraclium or Heracleoticum, the ſame alſo is divided into three ſorts: For the firſt is of a blacker and more duskiſh green, with broader leaves alſo than the reſt; and beſides is glutinous and will cleave to ones fingers. A ſecond ſort hath ſmaller leaves, ſofter it is and more tender in hand, not unlike to Majoram; and this kind ſome would rather call Praſium. The third hath leaves of a mean bigneſſe between the other two, not ſo large as the one nor ſo ſlender as the other, but not ſo forcible in operation as either of them both. But to return againe to our former Origanum: the beſt is that which groweth in Candie; for the ſame hath a pleaſant and ſweet ſent beſides: the next in goodneſſe is that which commeth from Smyrna: then after it, is the Origan that is brought from Heraclea: but that which is ſurnamed * Onitis, is ſimply the beſt of all others to bee taken in drinke. Howbeit, the uſe generally of them all in common, is to chaſe away Serpents: by way of decoction or pottage made therof, to cure them that be alreadie ſtung or wounded by them: beeing taken in drinke, to moove urine: and, togither with the root of Panace, to helpe ruptures, convulſions, and ſpaſmes: ſodden in certain Acetables with figs or hyſſope, to the conſumption of a ſixt part, to cure the dropſie. At the entrance into the ſtouve or hot-houſe if it be taken, good it is againſt the ſcab, the itch, and the wild ſcurfe. The juice with milke, is dropped into the eares, and that with very good ſucceſſe. It helpeth alſo the mumps or inflammation of the Amygdales and Vvula; likewiſe the ulcers in the head. The decoction thereof taken with lie aſhes in wine, is a countrepoiſon to kill the venome of Opium and Plaſtre. The meaſure of one Acetable, looſeneth the belly. A liniment made thereof, recovereth the native colour of the blacke and blew marks remaining after ſtripes. With honey and nitre, it aſſuageth the paine of the teeth if they bee rubbed therewith; and beſides maketh them looke faire and white. It ſtaunceth bleeding at the noſe. A decoction made therewith and barley meale, reſolveth the ſwelling kernels and inflammations behind the eares. The powder beeing incorporat in honey and gall-nuts, doth ſmooth and cleare the ruſtineſſe of the windpipes, occaſioned by a rheume. The leaves applied in manner of a cataplaſme with honey and ſalt, mollifieth the ſplene. If the hearbe be ſodden with honey and ſalt, and ſo taken by little and little, it doth cut, extenuat and make ſubtile, groſſe fleame, eſpecially if blacke melancholy bee bedded therein. Stamped, and inſtilled into the noſthrils with oile, it cureth the jaundiſe. Such as be overwearied and tired with extreame travaile, find much alleviation and eaſe by being rubbed and annointed all over with a liniment made thereof, with this caveat, That they come not ſo neare as to touch the belly with it. A plaſtre made with pitch and applyed, healeth the angrie bloudy-fals and chilblanes. Bruiſed with figs, it ripeneth felons. A pulteſſe made with it, with

K

* Bugle, or *Stæchas Arabica.*

L

M

oile,

A oile, vinegre, and barley meale, ſoſteneth and reſolveth the Kings evill. A liniment made therewith and figs togither, aſſuageth the paine in the ſides. Being bruiſed & reduced into a liniment with vinegre, & ſo laid to the privie parts, it reſtraineth the flux of blood thither; and yet it hath a propertie to evacuat the reliques of bloud, in women newly brought to bed, who ought to bee purged.

As touching Lepidium, [*i.* Paſſe rage] it is to be raunged among the burning and cauſticke medicines: by which facultie that it hath, and by bliſtering the skin, it taketh away any ſpot or blemiſh in the face; yet ſo, as the exulceration which it cauſeth, may be ſoone helped and skinned againe with a ſalve of wax and oile of roſes. By the ſame means it ſerveth to cleanſe the leproſie, and wild skabs, which it doth alwaies with eaſe and expedition; as alſo to ſmooth the cicatri-
B ces or skars after ulcers. Moreover, it is commonly ſaid, that if it bee tied faſt unto the arme, on that ſide where the teeth doe ake, it * taketh the paine quite away.

* To wit, by raiſing a bliſter and giving iſſue.

Gith or Nigella, the Greeke writers ſome name Melanthion, others Melaſpermon: the beſt is that which is blackeſt, and beſides of quickeſt ſent. A ſingular remedie it is for the ſores and wounds occaſioned by venomous Serpents and Scorpions eſpecially; if a liniment be made of it, vinegre, and honey mingled togither. I find alſo, that if it be burnt, the very ſmoke and perfume thereof will chaſe away Serpents: but particularly againſt the poiſon of venomous Spiders, a dram therof is ſufficient to be taken in drinke. Being bruiſed & knit in a linnen cloath, and ſo ſmelled unto, it reſolveth the poſe, or breaketh the cold which ſtuffeth the noſthrils. Applied as a liniment with vinegre to the forehead, or infuſed into the noſthrils, it eaſeth the head-ach.
C And if it be ſo uſed with the oile of the floure-de-lis root, it ſtayeth the wateriſh humors that fall into the eies, and abateth their ſwellings. The decoction thereof in vinegre, cureth the toothach, if a collution be made and the mouth waſhed therewith. Being ſtamped and ſo applied, or otherwiſe but chawed in the mouth, it healeth the cankers or exulcerations within. Likewiſe a liniment made of it and vinegre, cleanſeth the leproſie, and the hot red pimples breaking out in the skin. If it bee taken in drinke, with ſome addition of nitre, it eaſeth the difficultie of breathing, in ſuch as blow ſhort. It helpeth all hard ſwellings, and old feſtred impoſtumes or biles, if they be anointed therewith. If a woman be deſirous to have ſtore of milke, let her eat and drinke thereof continually every day. As touching the juice of Gith, it is drawne and gathered after the ſame manner as Henbane juice: and ſemblably, taken in any great quantitie, it is a very poyſon: which is a
D thing to be marveiled at, conſidering that the ſeed thereof ſeaſoneth loaves of bread, and giveth a moſt pleaſant relliſh to them. Moreover, the ſeed of Nigella cleanſeth the eyes, provoketh urine, and the monethly tearmes in women: yea and more than ſo, I read, that thirtie graines thereof tyed in a linnen cloth, and applyed to a woman newly delivered, will draw downe the after birth. They ſay alſo, that if it be ſtamped in urine and laid to the agnels or cornes of the feet, it cureth them: as alſo, that the ſmoke killeth gnats or any other flies.

As for the hearb Anniſe, if it alſo be drunke with wine, it is a countrepoiſon againſt Scorpions. And *Pythagoras* hath given a ſpeciall praiſe and commendation to it both raw and boiled, as to few other hearbs the like: for be it green or drie, it ſerveth as well for ſeaſoning of all viands, as making all ſauces; inſomuch as the kitchin cannot be without it. Over and beſides, when ba-
E kers ſet into the oven, they put Anniſe betweene the bottom of their loaves and the peele. And for to commend wine, Vintners uſe to put it into their Hypocras bagge, through which they ſtreine Hypocras and other aromaticall wines; and in deed with bitter Almonds it giveth a pleaſant and delicat taſt unto any wine whatſoever. If one chew it every morning upon an emptie ſtomacke faſting, together with the ſeed of Smyrnum, and a little honey, it maketh the breath ſweeter, and taketh away all ſtinking ſavours about one; provided alwaies, that the mouth bee preſently waſhed with a collution of wine. It cauſeth one to looke freſh and young. If it bee hanged about the bed upon travers or curtain, or otherwiſe ſticked to the pillow or bolſter, ſo as folke may have the ſent thereof in their noſthrils whiles they lye aſleepe, it riddeth them of troubleſome dreames and fantaſticall viſions. It procureth a good ſtomacke to meat: for ſo our idle,
F nice, and delicat wantons, ever ſince they have given over exerciſe and travaile (which ſhould get them an appetite and ſtomacke to their victuals) and betaken themſelves to ſit ſtill and doe nothing, have deviſed this artificiall meanes among others, and have recourſe to Anniſe: in which regards and for theſe cauſes, ſome have given it the name of Anicetum. The beſt of all commeth from Candie: the next unto it, is that of Ægypt: and indeed this ſerveth in ſtead

of Loveach in all ſauces. If a perfume thereof be drawn up into the noſe, it appeaſeth the head-ach. *Iollas* ſaith, That the Anniſe root bruſed and ſtamped together with wine, and ſo applied, ſtaieth the flux of waterie and weeping eies. The hearb it ſelfe with an equall quantitie of Saffron and wine, yea, or braied alone with Barley groats, reſtraineth all great fluxions and diſtillations: and the ſame compoſition applied to the eyes, driveth out any thing that hath fallen into them. A liniment made therwith and water together, conſumeth and cureth the Polypes or cankerous ulcers within the noſthrils. A collution of it in vinegre with Honie and Hyſſope, uſed as a gargariſme, aſſuageth the Squinancie. Tempered with oile of Roſes, it is ſoveraigne for the eares, to be inſtilled into them. Being taken, dried, and parched at the fire, it cleanſeth the breaſt of the viſcous and tough fleagme there gathered: but if it bee incorporat with Honie, it dooth the deed the better. But would you learne for the Cough a ſoveraigne Lohoch or confection? Take one Acetable of Anniſe, and fiftie *bitter nuts well cleanſed and blaunched, ſtampe theſe all together in a morter, and with Honey reduce them into the conſiſtence of an Electuarie. And yet there is one compoſition more for this purpoſe, and of all other the eaſieſt and ſooneſt made. *Recipe*, Of Anniſe three drams, of Poppie ſeed two drams, temper theſe with Honie: and for three mornings together take the quantitie of a Beane, faſting. And this confection is ſingular beſides againſt ſoure riftings or belching: and therefore it cureth the ventoſities which puffe up the ſtomacke: it aſſuageth the torments and wrings of the guts, and repreſſeth the continuall flux proceeding from the weakeneſſe of the retentive facultie in the ſtomacke. But to returne againe to ſimple Anniſe ſeed, a drinke made with the decoction therof, or the very ſmell taken up into the noſe, ſtaieth the troubleſome yex or hocquet. The decoction of Anniſe leaves doth digeſt and reſolve all crudities. The juice drawne from it when it is ſodden with Perſeley, if it be ſmelled unto, ſtinteth immoderat ſneeſing. Moreover, Anniſe taken in drinke, procureth ſleepe, expelleth the ſtone and gravell, ſtaieth vomites, and reſolveth the tumours in the precordiall parts, cauſed of windineſſe. Furthermore, it is a moſt ſoveraigne medicine for the diſeaſes in the breaſt: comfortable alſo to the nervous parts, membranes, and ligaments, wherin the muſcles of the bodie be either encloſed or tied and united together. The juice of it beeing boiled with oile, and ſo dropped or inſtilled into the head, is good for the paines thereof. It is thought that there is not a better thing for the bellie and the guts, than Anniſe; and therefore it is given ordinarily (if it be firſt parched and roſted againſt the fire) in caſe of the bloudie Flix and the exulceration of the guts: alſo for the inordinat profers to the ſeege, and riſing from it without effect or any thing diſcharged. Some put thereto Opium alſo, and preſcribe to make three pils thereof, to the bigneſſe of a Lupine ſeed, and to take them every day diſſolved in a Cyath of wine. *Dieuchès* uſed commonly the juice of Anniſe, for to mitigate the paine of the loines: to give alſo the ſeed beaten to pouder with Mints in wine, for the Dropſie and the defluxion Stomachicall: but the root hee thought to be paſſing good for the kidneies, uſed and taken in that manner. *Dalion* that famous Herbariſt, was wont to applie Anniſe and Perſeley together in forme of a cataplaſme, to women in labour, for better ſpeed in child-birth: alſo for the paine of the Mother, yea, hee would give it alſo to drinke with Dill, unto women when they cried out in travell. He applied it alſo green, with Barley groats in manner of a liniment, to the head, for to ſtay and ſettle the braines of franticke perſons. And being ſo prepared, he found it ſingular good for young infants ſubject to the falling ſickneſſe, or troubled with crampes and contractions of ſinewes. As for *Pythagoras* verely, he ſaith confidently, That whoſoever doe but hold this hearbe in his hand, he ſhall not bee ſurpriſed with a fit of the falling evill: and therefore he adviſeth folke to ſow good ſtore of it in their gardens about their houſes, to be readie ever at hand. He affirmeth moreover, That women in labour if they ſmell thereto, ſhall have more ſpeedie and eaſie deliverance. Hee giveth counſell beſides, that immediatly after the child is borne, the mother ſhould drinke a grewell made with it and ſome Barley groats ſtrewed among. *Soſimenes* the Phyſician was wont to molliſie and reſolve all hard ſwellings with Anniſe and Vinegre: hee uſed alſo to give the decoction thereof in oile, with ſome ſprinckling of Nitre among, to thoſe that felt wearineſſe in their lims. Moreover, he aſſured travellers and wayfaring men, that if they dranke the ſeed thereof, they ſhould find preſent helpe if they were tired. *Heraclides* gave ordinarily of the ſeed as much as might be taken up with three fingers, together with two Oboles of Caſtoreum, in honied wine, for the hoving and inflation of the ſtomacke: ſemblably, for the puffing up and ſwelling of bellie and guts. Alſo, to thoſe that were ſtreight winded, & could not take their breath but ſitting upright, he miniſtred the like

*i. Almonds.

pro-

A proportion, to wit, as much as three fingers would containe, with equall quantitie of Henbane ſeed, in Aſſes milke. Many Phyſicians give counſell to thoſe that would vomit luſtily, for to drink in water as they ſit at ſupper, an acetable thereof and ten leaves of Baies, bruiſed and beaten into pouder. If Anniſe ſeed be chewed, or applied hot in forme of a liniment, yea, or taken as a drinke in vinegre and honey, together with Caſtoreum; it helpeth the riſing of the mother & the daunger of ſuffocation thereby. If a woman in child-bed preſently upon her deliverie, drinke it with cucumber ſeed and line ſeed together, of equall quantitie, namely, as much as may bee held betweene three fingers, in three Cyaths of white wine; it will ſettle the lightneſſe of the braine, and ſtay the dizzineſſe of her head. *Tlepolemus* preſcribed for fevers Quartane, as much Anniſe ſeed as three fingers might comprehend, with the like quantitie of Anniſe and Fennell ſeed to be ta-
B ken in vinegre and one Cyath of Honie. A liniment made with Anniſe and bitter nuts, allaieth the greevous paines of the Gout. There be who are of opinion, That it hath a ſpeciall vertue and propertie to reſiſt the poyſon of the Aſpis. Certain it is that it provoketh urine, allaieth thirſt and the appetite to drinke, yea, and ſolliciteth to carnall luſt. Taken in wine, it gently putteth foorth a kind ſweat. Moreover, it keepeth cloths and apparell from the moth. Generally, the freſher and newer awaies that it is, and the blacker that it looketh, the more effectuall it is found to be. Howbeit, this one diſcommoditie it hath, That it is an enemie to the ſtomacke, unleſſe haply it bee peſtered with ventoſities.

Chap. XVIII.

C *Of Dill: of Sacopenium, and Sagapenum. Of Poppie both white and blacke. The manner of gathering and drawing juice out of hearbs. Alſo of Opium.*

Dill alſo hath a propertie to diſſolve ventoſities, to breake wind and cauſe rifting: alſo to aſſuage any wrings or torments of the bellie, and yet it ſtaieth the flux. The roots beeing reduced into a liniment with water or wine, reſtraineth the flux of watering eies. A perfume made of the ſeed as it boileth, received up into the noſthrils, ſtaieth the yex. Taken as a drinke in water, it concocteth crudities, and appeaſeth the paine of windineſſe proceeding from thence. The aſhes of it burned, raiſe up the Vvula in the throat that is fallen. Howbeit, Dill dimmeth the eyeſight, and dulleth the vigor of genitall ſeed.

D As for our Sacopenium here in Italie, it differeth altogether from that which groweth beyond ſea. For the outlandiſh kind, reſembling gum Ammoniacke, is called Sagapen. Good it is for the pluriſie and paine of the breaſt, Convulſions or Spaſmes, and old ſettled Coughs; for thoſe that reach up filthie and rotten matter; for the tumors of the Midriffe and precordiall parts. It cureth the ſwimming and giddineſſe of the head, the ſhaking and trembling of the joints, the cramp or convulſion that draweth the necke backward, the great ſwelled ſpleenes, the paine of the bones, and all ſhaking and quivering colds. A perfume made therewith in vinegre, if a woman ſmell unto, it helpeth the Mother that is ready to ſtop her wind. As for the other accidents, it is both given in drinke, and alſo rubbed into greeved parts with oyle. It is thought to bee ſoveraigne alſo againſt poyſoned drinkes given by Witches and Sorcerers.

E Touching garden Poppie and the ſeverall kinds thereof, I have written already: but beſides them there be other ſorts alſo of the wild, whereof I promiſed to treat. Meane while, the heads of the foreſaid garden white Poppie, if they be bruſed whole as they grow with ſeed and all, and ſo drunke in wine, doe procure ſleepe. The ſeed of it ſelfe alone cureth the Leproſie. *Diagoras* giveth counſell to cut the ſtem or ſtalke of the blacke Poppie when it beginneth to ſtrout and ſwell toward the flouring time, out of which there will iſſue a certaine juice called Opium: but *Iollas* adviſeth to make that inciſion when it hath bloumed, and to chuſe a faire cleare day for it, & that houre of the day when as the deaw thereon is dried up. Now would they have them to be cut under the head before the bloume; but in the very head, after it hath done flouring: and verely, ther is no other kind of hearbe wherein the head is cut, but this onely. The ſaid juice of this hearbe as
F well as of all other is received in wooll: or elſe if it run but in ſmall quantitie, they gather it with the thumbe naile, as the manner is in Lectuces: but the morrow after the inciſion, ſo much the more vigilant they muſt be to ſave and gather that which is dried. And in very deed the juice of Poppie commonly runneth out in great abundance, and gathereth into a thickneſſe: which afterward is ſtamped and reduced into little troſches, and dried in the ſhade. Which juice thus

drawne

drawne and thus prepared, hath power not onely to provoke ſleepe, but if it be taken in any great quantitie, to make men die in their ſleepe: and this our Phyſicians call Opion. Certes, I have knowne many come to their death by this meanes: and namely, the father of *Licinius Cecinna* late deceaſed, a man by calling a Pretour, who not able to endure the intollerable pains and torments of a certaine diſeaſe, and being wearie of his life, at Bilbil in Spaine, ſhortened his owne daies by taking Opium. By reaſon whereof, Phyſicians are growne to great variance, and bee of contrary opinions as touching the uſe of the foreſaid Opium. *Diagoras* and *Eraſiſtratus* condemned it altogether as a moſt deadly thing, & would not allow that it ſhould be ſo much as injected or infuſed into the bodie by way of clyſter: for they held it no better than poyſon: and otherwiſe hurtfull alſo to the eies. *Andreas* ſaith moreover, That if Opium dooth not preſently put out a mans eies and make him blind, it is becauſe they of Alexandria in Ægypt do ſophiſticat it. But in proceſſe of time the later and moderne Phyſicians did not utterly reject it, but found a good uſe thereof, as may appeare by that noble and famous Opiat confection called Diacodium. Moreover, there bee certaine ordinarie troſches made of Poppie ſeed beaten into pouder, which with milke are commonly uſed by way of a liniment to bring ſicke patients to ſleepe. Likewiſe with oile Roſar, for the head-ach: and with the ſame oyle they uſe to drop it into the eares for to mitigat their paine. Alſo a liniment made thereof with breaſt-milke, is ſingular good for the gout. In which ſort there is a great uſe of the leaves alſo to the ſame purpoſe. And beeing applied as a cataplaſme with vinegre, they helpe S. *Anthonies* fire, and all ſorts of wounds. For mine own part I would not have it in any caſe to enter into Collyries, much leſſe unto thoſe medicines which be ordained to drive away aged fits, or into maturatives, no nor to goe among other ingredients into thoſe remedies which are deviſed for to ſtay the flux that commeth from the ſtomacke. Howbeit, in this caſe laſt ſpecified, many give the blacke Poppie with wine. All garden Poppies grow rounder in the head than the wild: for theſe bear a head longer and ſmaller, howbeit (for any uſe) of greater operation than thoſe of the garden. For the decoction thereof taken as a drink, procureth ſleepe to ſuch as bee over-watchfull: ſo doth a fomentation thereof, if either the viſage bee ſprinckled, or the mouth waſhed therewith. The beſt Poppies bee they that grow in drie places and where it raineth ſeldome. When the heads and leaves both be ſodden and ſtamped, the juice that is preſſed from them, Phyſicians call Meronium: and it is far weaker and duller in operation than Opium. Now to know which is good Opium indeed, the firſt and principall triall is by the noſe; for the true Opium is ſo ſtrong, that a man may not endure to ſmell it. The ſecond proofe is by fire: for the right Opium will burne cleare like a candle; and when it is put forth, yeeldeth a ſtinking ſent from it in the end: which ſignes are never to bee found in that which is falſified and ſophiſticat: for this that is not right, will not ſo ſoone take a light fire, and beſides, is readie oftentimes to goe out. There is another experiment by water: for the good and pure Opium beeing put into water, ſendeth forth a certaine miſt from it like a cloud, which floteth even aloft: whereas the corrupt and depraved Opium gathereth into bliſters and bladders, and ſo bubbleth upon the water. And yet there is one way more admirable than the reſt to trie good Opium even by the Sunneſhine in a Summers day: for if it be ſuch as it ought, it will ſweat and reſolve into a thin liquor, like as when it came firſt out of the plant. To conclude, *Meneſicles* is of opinion, That the beſt meanes to keepe and preſerve Opium, is to lay it among Henbane ſeed: but others thinke it better to let it lie among Beans.

Chap. xix.

*Memithum.

*Of the wandering Poppie, and the horned Poppie. Of *Glaucium or Paralium. Of Heraclium or Aphrum. Of the compoſition named Diacodium, and of the Tithimal.*

IN a middle nature betweene the garden Poppie and the wild, is to bee raunged a third kind: which becauſe it commeth up in corne fields, but yet unſowne and of the own accord, we have called Rhœas, and wandering Poppie. Some there be, who ſo ſoon as it is gathered, chew both hearbe and head all whole as it grew, and ſo eat it. Five heads of this Poppie beeing ſodden in three hemines of wine, and ſo taken in drinke, doe both purge the bellie, and alſo bring the patient to ſleepe.

Of theſe wild Poppies, there is one kind called in Greek Ceratitis, of a darke or duskiſh green, growing up with a ſtalke a cubit high; with a groſſe root, & the ſame covered with a thick rind; the heads

A heads or cups wherein the seed lieth, bend like unto a little horne. The leaves are lesse and slenderer of this Poppie than of any other wild. The seed also is small, ripe and readie to be gathered in corne harvest; which beeing taken in drinke, to the quantitie of halfe an Acetable in honied wine, worketh downewards and scoureth the bellie. The leaves being stamped with oyle, and so applied, heale the haw in horse eyes. The root taken to the quantitie of an Acetable, and sodden in two sextars of honied wine, untill halfe bee consumed, is given in drinke for the infirmities of the loines and liver. The leaves applied as a cataplasme with Honey, healeth Carbuncles. Some call this kind, Glaucium, others Paralium: for it groweth within the aire of the sea, or els in some brackish place standing much upon Nitre.

Another kind of these wild Poppies is called of some Heraclion, or of others, Aphron, with
B leaves resembling* Sparrowes, if a man looke a farre off. The root runneth very ebbe and superficially under the greene sord, and the seed seemeth charged with a certaine froth or fome. Herewith linnen cloths in Summer time use to bee bleached, and to get a bright white colour. This hearbe beaten in a morter to the quantitie of one Acetable, and taken in white wine, helpeth the falling sickneesse: for it causeth the patient to vomit. This kind of Poppie is the principall ingredient or Basis to the confection named Diacodium or Arteriacum. The composition or making whereof ensueth in this manner: Take of this Poppie heads, or of any other of the wild sort, one hundred and twentie: let them lie in soke or infused two daies together in three sextares or halfe a gallon of water: and in the same water boile them well. When this decoction hath passed through a strainer or jelly bag, seeth it a second time with Honie up to the height or consistence
C of a Syrrup (that is to say, untill halfe be consumed away) over a soft and gentle fire. Here unto the modern Physicians which came after, put too, of Saffron, of Hypocisthis, Frankincense, Acacia, of each six drams; and in the end, of grosse cuit of Candie one sextar. But this latter composition served onely for a shew and vaine ostentation; for the simple and plaine making of it in old time with Honie and Poppie, and no other addition besides, was as wholesome and profitable as this. But to come againe to our wild Poppies: there is a third kind thereof named Tithymalos, (which some call Mecon, others Paralion) carying a smooth leafe and a white, with a head of the bignesse of a Beane. The time of gathering these Poppies, is when the grape is in the floure: and then the manner is to drie them in the shade. The seed if it bee taken in drinke, the quantitie of halfe an Acetable in meade or honied wine, purgeth the bellie. But what Poppie soever it be, the
D head either greene and fresh, or drie, if it be applied as a liniment to the eies, represseth the flux of waterish humors falling to them, and mitigateth their inflammations. If Opium bee given in pure wine somewhat allaied, presently after the Scorpion hath stung, it is a countrepoyson. Howbeit, some there bee who attribute this vertue onely to the blacke Poppie, namely, if either the heads or leaves be brused and reduced into pouder.

**Struthio similibus, ex Dioscor.* i. like to Struthium. Wherin *Plinie* is foulely overseene to translate it *passerem presentantibus*: because that στρουθιον signifieth the hearbe Struthium, (i. Fullers weed) and the bird called a Sparrow: upon which one absurditie, more follow still to maintaine the same, as commonly it is seene. For that which followeth of bleaching, agreeth to the foresaid hearb in some sort.

Chap. xx.

Of the wild Purcellane or Peplium. Of Coriander and Orach.

E THere is a wild Purcellane also, which they call Peplium: more effectuall, though not much, than the Garden Purcellane; for there be strong and wonderfull properties reported thereof for sundrie uses. First it is holden for certaine, that this hearbe if it bee eaten as meat, dulleth the poyson of venomous arrowes, of Serpents also called* Hæmorrhoids and* Prester: and being laid to the hurt place, draw forth the said poyson. The juice also of this hearb pressed forth and drunke in wine cuit, is a remedy for those that be poysoned with Henbane. Now if the hearb it selfe is not to bee gotten, the seed hath the like effect. Moreover, it is thought to bee singular good for the aquosities gathered within the bodie, and the diseases caused thereby, as Dropsies, &c. for the head-ach; for rheumaticke ulcers also, if it be brused and applied with wine. All other sores likewise it healeth, if it be chewed and laid too with Honey. After the same manner prepared, it is good to bee applied to childrens heads for to temper the heat of the braine, as also to
F their navils when they beare out more than they should. For all vehement distillations of waterie humors into the eyes, as well of old folke as small infants, it is counted singular; for to bee applied to the forehead & temples, together with Barley groats: but if it be laid unto the very eyes, then would the same be tempered with milke and honey. Now if it chaunce that the eies bee readie to fall out of the head, the leaves stamped with the shales of Beane cods, and applied therto,

**So called for that they cause flux of bloud.* **Otherwise named *Dipsades*, because they set one into a burning fire (as it were) and an unquenchable thirst: whereupon they tooke both their names.*

is

is an excellent remedie. A cataplasme made of it, with Barley groats, salt, and vinegre, cureth angrie wheales and blisters that breake out in the skin. The same beeing chewed raw, represseth the cankers in the mouth, and the smelling of the gums: likewise, it assuageth the tooth-ach. The juice of it being well sodden, cureth the sores of the Amygdales, if the mouth and throat be washed therewith. And some put to this collution a little pouder of the stone Murra. And no mervaile, for the very chewing onely thereof doth fasten the teeth that be loose in the head. It doth mitigat the inconvenience of cruditie and indigestion, it strengtheneth the voice, and putteth by thirst. A cataplasme made therewith, having gall nuts and line seed among, of equall quantitie, allaieth the paines and crickes in the nape or chine of the necke. Tempered with Honey and white Fullers cley, it is singular for the accidents that befall to womens breasts. The seed taken with Honey, is very holesome for such as be short winded. Eaten in sallades, it strengtheneth the stomack. If it be laid as a cataplasm [to the bellie and Hypochondriall region] it allaieth the heat of ardent and burning fevers: yea, and in other cases the very chewing of it cooleth the heat of the guts and entrails. It staieth vomits, eaten in vinegre: or taken in drinke with Cumin, it is good for the bloudie flix and other inward impostumes and filthie sores. Beeing first sodden and then eaten, it is singular for those that straine hard upon the stoole, and notwithstanding many provocations and profers, deliver nothing. And whether it be taken in meat or drinke, it is a soveraigne thing for the falling sickenesse. For a shift or immoderat course of womens tearmes, it is given with great successe, the quantitie of one Acetable measure in wine cuit. A liniment made with it and salt, is good for the hote gout and S. *Anthonies* fire. The juice if it be drunken, helpeth the reines and the bladder. It expelleth wormes and such like vermine out of the bellie. A good mitigative, it is of paine, if it be applied as a cataplasme to wounds with oile and Barley groats. It mollifieth the stiffenesse and hardnesse of the sinewes. *Metrodorus* in his booke entituled the *Abridgement or Breviarie of those roots that are to becut up or gathered; gave counsell to give this hearbe to women, newly laid upon child birth, for the immoderate and excessive purgation that many times followeth them. It cooleth the heat of lust, and represseth dreames of wantonnesse. I know my selfe a grand signior in Spaine, father unto a great personage, and one who had been advaunced to the dignitie of a Pretour, who caried ever about him a root of this Peplium hanging at his necke by a lace or small thred, and that for the intollerable paines of the Vvula, whereto he was subject: and never would he leave it off, but when he went into the stove or bain: whereby he found such ease, that hee was never troubled afterward with the said disease. Moreover, I have read in some writers, That if the head bee annointed or well rubbed therewith, a man shall not for a year together find any inconvenience of a rheume distilling from the brain. Howbeit, it is thought that the use thereof will make the eyes dim.

*Ὀπτημένη ἢ ῥιζοτομουμένων.

Concerning Coriander, there is none found growing wild of it selfe without sowing by the hand. But certaine it is, that the very best commeth out of Ægypt: a speciall and peculiar vertue it hath against one kind of serpent or venomous worme, which they call Amphisbæna [for that it seemeth to have an head at both ends] whether it bee inwardly taken in drinke, or outwardly applied. It healeth also other wounds. It cureth the night-foes or chilblanes, the red angry pimples also, if it bee but onely stamped and laid too. There is not a swelling or apostemation gathering to an head, but a cataplasme made with it with Honey and Raisins, either resolveth them, or quickly bringeth to maturation. If it bee no more but stamped with vinegre, it easeth the pushes and biles that breed commonly in the ordinarie emunctories. Three graines of Coriander seed, some prescribe to be eaten before the accesse or fit of a Tertian ague: or more than three to be rubbed upon the forehead. Others there are who thinke, that to the same effect they are to be laid under the bolster and pillow where the patient lieth, before the Sunne rise; and then shall he be sure to misse his fit and be warished for that fever. Indeed, Coriander whiles it is greene, is of great force to coole the heat of agues. A cataplasme thereof made with Honey or Raisins, healeth ulcers also that be corrosive and eat deep into the flesh. In like manner so prepared, it is very good for the privie membres; for burnes and scaldings, for carbuncles, and for the eares. With womans milke it helpeth eyes that water continually. The seed drunke in water, staieth the flux of the bellie and guts: yea, and in case of those violent evacuations upward and downward, through the rage of chollericke humors, being taken in drinke with Rue, it settleth and knitteth the body againe. If the seed of it be drunke with sallet oyle and the juice of a Pomgranat, it chaseth foorth wormes out of the entrails. *Xenocrates* telleth a straunge thing, if it be true, namely, That if a woman

A man drinke one onely graine or ſeed of Coriander, her menſtruall flux will ſtay one day: if twain, they will hold up two daies; and proportionably, looke how many ſeeds ſhee drinketh, ſo many daies ſhall ſhe goe cleare and ſee no token of them. *M. Varro* was of opinion, That if fleſh meat were poudered or corned with Coriander groſſe beaten together with vinegre, it would keepe ſweet, and it were all the Summer long.

As for Orach, there is a wild kind of it growing of the owne accord: a very weed it is and no better, utterly condemned by *Pythagoras*; as if it bred the Dropſie, engendred the Iaundiſe, brought folke to looke ill and pale, and were exceeding hard of digeſtion: and ſo farre hee was
B out of conceit with it, that hee thought nothing would like well and proſper, no not in a garden, where this grew near, but that it would ſenſibly decay and fade. *Dionyſius* and *Diocles* approve this judgement of *Pythagoras*, and ſay moreover, That moſt diſeaſes are bred therby. Nay, they would not have it to be put into the pot to be ſodden, unleſſe it had been waſhed before in many waters: Theſe Phyſicians hold that it is a very enemie to the ſtomack, engendring pimples, freckles, and whelkes. But I muſe and marvell much why *Solon* of Smyrna ſhould write, that it hath much ado to grow and come up in Italie. As for *Hippocrates*, he is not ſo far fallen out with it; for with it and Beets he maketh a decoction (to be injected by the Metrenchyte) to aſſuage the inflammation in the Matrice and the naturall parts of women. *Lycus* of Naples was wont to give it to drinke as a countrepoyſon againſt the green flies Cantharides. And he thought that a very good liniment might be made thereof, either raw or ſodden, to lay unto biles, puſhes, fellons a breeding, and all hard tumors whatſoever. Semblably, that if S. *Anthonies* fire were annointed therewith, beeing
C incorporat with hony, vinegre, and nitre; or if it were applied unto the goutie parts, there would enſue great eaſement. Moreover, in caſe the nailes be growne crooked, uneven and rugged, it is ſaid that it will cauſe one to caſt them without any ulcer and ſore at all. Some there be who preſcribe an Electuarie, made with the ſeed of Orach and Honey, to be given for the Iaundiſe. Alſo, if the windpipes be hoarſe with ſome fell and ſharpe rheume falling downe upon them, or, if the Amygdales on either ſide of the throat bee amiſſe, it is very good to rub thoſe parts therewith. They affirme moreover, That a ſimple decoction of it alone, moveth the bodie downeward; but with Mallows or Lentils, provoketh upward and cauſeth vomit. Finally, to conclude with the wild Orach: it is uſed much to colour the haire black, and for the other abovenamed purpoſes, as well as that of the gardens.

D

Chap. XXI.

Of the common Mallow. Of the Mallow Malopum. Of the marſh mallow or Althæa. Of the common Docke: the ſoure Docke or Sorrell: of the water Docke: of the tall Docke called Patience: and laſtly of that Docke with the long root, called Bulapathum.

ORaches were not ſo much diſcommended, but on the contrarie ſide Mallowes be as highly praiſed, as well that of the garden as the wild. Two kinds there bee of the garden Mallowes; diſtinguiſhed both, by the largeneſſe of their leaves. The greater of thoſe that grow
E in gardens, the Greekes call Malopum; the other is ſuppoſed to be named Malachum, for that it doth mollifie and ſoften the bellie. Of the wild ſort, that which carrieth a broad leafe and white roots is called *Althæa, and of ſome, Ariſtalthæa, for the excellent vertues that it hath in Phyſicke. This propertie have Mallows, To enrich and fatten any ground, whereſoever they be ſowne or ſet. But this mariſh Mallow Althæa, is more effectuall than the reſt againſt all wounds by ſharpe prickes or thornes, and principally againſt the ſting of Scorpions, Weſpes, and ſuch like, as alſo the biting of the Hardiſhrew mouſe. Nay, whoſoever be throughly rubbed or annointed beforehand with any Mallow whatſoever, ſtamped with oile; or doe but carie it about them, they ſhall not be ſtung or bitten at all. As for the leafe of Mallowes, if it bee laid upon a Scorpion, it will be ſtreightwaies benummed. Moreover, good countrepoyſons they be all. A liniment made
F of them being raw together with nitre, draweth forth all prickes or ſtings remaining within the fleſh: but if leafe and root be ſodden together and ſo drunke, it repreſſeth the poyſon of the venomous fiſh called the ſea-Hare: but ſome ſay it muſt be caſt up and vomited againe, or elſe it doth no good. Certes, ſtraunge and wonderfull things bee ſpoken as touching the operation of Mallowes, over and above thoſe alreadie rehearſed. But this paſſeth all the reſt, That if a man or

* Κατὰ τὰ ἀλθαίνειν. To cure or heale.

woman

woman ſup off a ſmall draught (thought it were no more but halfe a cyath) every day of the juice G
of any mallow, it skills not which, he ſhall be free from all diſeaſes and live in perfit health. True
it is, that if they be putrified and reſolved in chamber-lye, they will heale all the ſcurfe & running
ſcalls in the head: but if they be tempered with hony, a collution made therof cureth the cankers
of the mouth: and a lavature repreſſeth all tettars, ringworms, & any ſuch wild fire running upon
the skin. A decoction of the root, cleanſeth the head of dandruffe, if it be waſhed therewith; and
ſetteth the teeth faſt that were looſe. Take the root of that Mallow which riſeth up with one only
ſtem, pricke the gumbs therwith about the tooth pained; doe this (I ſay) untill the ach be gone.
The ſame root reduced into a liniment, with the faſting ſpittle of man or woman, and applyed
accordingly; reſolveth the Kings evill, diſpatcheth the ſwelling kernels behind the ears, and diſ-
cuſſeth biles and puſhes, without any breaking of the skin or making ulcer. The ſeed of mal- H
lowes if it be taken in thicke wine, delivereth the Patient from phlegmaticke humors, from the
rheume, and the heaving of the ſtomacke making offer to caſt and cannot. The root wrapped
faſt and tied within a locke of blacke wooll, preventeth the evill accidents that may befall unto
womens breaſts. The ſame ſodden in milk & taken after a ſuppling ſort (in manner of a ſupping)
for five daies togither, cureth the cough. And yet *Sextius Niger* ſaith, they be huttfull to the ſto-
macke: And **Olympias* of Thebes affirmeth, That if women uſe it with gooſe greaſe, they ſhall
not goe their full time with child. Others doe write, That if women take an handfull of Mallow
leaves in oile and wine, they ſhall bee throughly purged in their due times. This is knowne for a
truth and reſolved by all that write or make profeſſion of Phyſicke, That a woman in labour, if
ſhee ſit upon Mallows ſtrewed under her ſtoole, ſhall bee delivered with greater ſpeed and expe- I
dition: but then muſt they bee taken away preſently after that ſhee is laid, for feare that the very
matrice follow after the child. An ordinary practiſe it is of ſage and diſcreet midwives, To give
unto women in travaile faſting, a ſmall pint of the juice of Mallows ſodden in wine: & yet thoſe
that cannot containe but ſhed their naturall ſeed, are enjoyned to take Mallow ſeed bruſed, and
ſo to bind it to their arme. Moreover, ſo good and favourable naturally be Mallows to the game
of love, as if they grew for nothing els: inſomuch as *Democrates* doth affirme, That if the ſeed
of that Mallow which runneth up in one ſtalke, bee reduced into powder and ſtrewed upon that
part of a woman which Nature hath hidden, ſhee will bee ſo wood after the companie of a man,
as ſhe will never be ſatisfied nor contented with embracing. The like effect (ſaith hee) there will
enſue, if three roots thereof bee bound neare to the place of nature. Alſo, that a decoction of K
Mallows miniſtred by way of clyſter, is a ſingular injection to cure the bloudie flix, or exulcera-
tion of the guts; as alſo the extraordinarie and bootleſſe deſire to the ſeege. In like manner, a
fomentation thereof is very good for other accidents befalling to the ſeat or tuill. The juice of
Mallows is given warme, the quantitie of three cyaths, to melancholique perſons that bee trou-
bled in mind; and of foure, to thoſe that be ſtarke mad indeed and beſides themſelves. A whole
hemina of the juice drawne and preſſed from Mallows boiled, is given at one time to thoſe that
be ſubject to the falling ſickneſſe. The ſame beeing reduced into a liniment, is to good purpoſe
applyed warme unto thoſe, who are troubled with the ſtone and gravell, with wind cholique and
ventoſities, with the crampe alſo or cricke that doth draw their necks backward. The leaves be-
ing ſodden in oyle, are laid with good ſucceſſe in manner of a cataplaſme, upon the hot fretting L
humor called S. *Anthonies* fire: alſo to places ſcorched, burnt, or ſcalded: but for the accidents
and Symptomes concurrent with wounds, they bee rather laid raw with crumbs of bread. The
juice of Mallows boiled, is comfortable to the ſinews, the bladder, and the fretting or grinding
of the guts. Mallows being either eaten, or their decoction miniſtred by way of injection with a
metrenchyte, mollifieth the ſaid tumors in the matrice. The juice of Mallows well ſodden, either
taken in drinke or applyed by way of fomentation, enlargeth the Vretere conduits, and giveth
good and eaſie paſſage for the urine. The root of Althæa is more effectuall to all theſe infirmities
and purpoſes above-named, than of any other Mallow; but eſpecially in caſe of convulſions,
cramps, and ruptures. If it be ſodden in water, it bindeth the belly. Boiled in white wine and ap-
plyed as a cataplaſme, it reſolveth the ſwelling kernels, commonly called the Kings evill; thoſe M
alſo that appeare behind the eares; yea and the inflammations of the paps and breaſts. As for
the biles or riſings called Pani, the leaves of Althæa or the mariſh Mallow ſodden in wine and
brought to the forme of a liniment, doe diſcuſſe and rid away. The ſame, after they be drie, and
ſodden in milke, cure the cough, how tough and ſhrewd ſoever it were, and that moſt ſpeedily.

Hippocrates

* A woman Phyſician, who wrate of Phyſick, or at leaſt-wiſe a midwife of good authoritie.

A *Hippocrates* gave counsell to them that were wounded, and for losse of bloud exceeding thirstie, for to drinke the juice of Althæa roots sodden. Hee saith moreover, That the root it selfe emplastred with honey and rosin, is good for wounds, bruises, dislocations, and swellings: comfortable also to muscles, sinews, and joynts. He gave it likewise to those that were troubled with difficultie of taking wind, and with wheezing; for the dysenterie also or bloudie flix, to be drunken in wine. A wonderfull thing of this root, that if it bee put into water, and the same let to stand abroad in the open aire, the water will gather to a thickenesse and cruddle, yea turn white it will like milke. To conclude, the newer and fresher that Althæa is, the more effectuall you shall find it in operation.

Touching the Docke, the proprieties thereof are not unlike to those of the marsh Mallow. There is a wild kind thereof, which some call Oxalis in Greeke, [*i.* wild Sorrell, or Soure-docke] B this hearbe resembleth very neare that of the Garden, in regard of the sharpe pointed leaves; in colour like the white Beet, having a very small root: our countreymen name it in Latin Rumex; other Lapathum Cantherinum: This hearbe being incorporat with hogs grease, is singular to mollifie all the swelled kernels, which some call the King evill. A second sort there is, which commonly is called Oxylapathum, *i.* Sharpe pointed Docke; this commeth yet neater to the garden Docke than the former: for it hath leaves sharper at the point and redder, and groweth not but in marish grounds. There is another kind of Docke comming up in the very water (as some say) Hydrolapathum. Yet is there one more called * Hippolapathum, bigger than the garden Docke or Sorrell; white also, and of a more fast and pulpous substance. As for all the wild Dockes or Sorels, they be holden medicinable to cure the stings of Scorpions; and whosoever C hath any of them about him, is secure from the sting or pricke of Scorpions. The root, if it bee sodden in vinegre and strained, the juice thereof if the mouth be washed therewith, helpeth the teeth-ach: and if the same be taken in drinke, it cureth the jaundise. The seed of this hearbe remooveth the tough humors bedded in the stomacke, how hard impacted soever they be. The roots of Patience have this peculiar propertie, To cause the nailes to fall off that grow rugged and uneven. The seed taken to the weight of two drams in wine, riddeth away the bloudy flix. The seed of the sharpe Docke being washed in raine water, is singular good for those that reach and cast up bloud, if there be added thereto as much Acacia as the bignesse of a Lentill. There be most excellent Trochisques made of the leaves and root thereof, with the addition of nitre and some little quantitie of * convenient liquor, to incorporat and unite them: and these must be D infused and dissolved in vinegre, at the time that they are to be used. As touching the garden Sorrell, there is a liniment made thereof, which beeing applyed in manner of a frontall to the forehead, cureth the distillation of the waterie humors to the eyes. The root is singular for the wens or impostumes called Melecerides, and likewise of the Leprie. The decoction in wine is as good for the stone and gravell; as also to resolve the Kings evill, and the swelling kernels behind the ears. If the seed be drunke in wine, it helpeth the splene and the tumors therof: the bloudie flix likewise, the stomachicall flux, and the vaine desire to the stoole without effect. But for all these purposes, the juice of the Docke is more effectuall. Over and above, it breaketh wind upward, it provoketh urine, and discussеth the cloud and mist that troubleth the eyes. If this hearbe be put under the bathing tub within the baine, or otherwise if the bodie be annointed with a li- E niment thereof without oile, before one enter into the bath, it taketh away the itch. If the root be but chewed onely, it fasteneth the teeth that shake in the head. The same root sodden in wine, stayeth the flux of the belly, and bindeth it; and yet the leaves make the bodie soluble. Finally, (because I would willingly omit nothing) *Solon* hath made mention of another Docke, called Bulapathum, nothing different from other Dockes, but that the root runneth deeper into the ground, which, if it be taken in wine, cureth the bloudie flix.

* *i.* Patience, or Monks Rheubarb.

* *Jure*, haply for *Thure*, *id est*, Frankincense, according to *Cornarius*.

Chap. XXII.

Of three kinds of Senvey: of Horehound, and wild running Thyme: of water Cresses: of water Mints, otherwise called Thymbræum: of Lineseed, and Bleets. F

THe hearbe Senvey, whereof there be three kinds (as I have alreadie observed in my treatise of Garden plants) *Pythagoras* hath placed in the highest ranke of those Simples that fume up aloft: for there is not a thing that sooner biteth one by the nose, and pierceth & moun-

teth more quickly into the brains than doth Senvey. The ſeed thereof [commonly called mu- G
ſtard ſeed] being ſtamped, & with vinegre reduced into a liniment, cureth the ſting of Serpents, and namely the prick with the Scorpion. It hath beſides, a ſingular vertue to mortifie and kill the venomous qualitie of muſhroms. If it bee but held in the mouth untill it melt and reſolve, or otherwiſe be gargariſed with honeyed water, it draweth waterie fleame out of the head. Beeing chewed, it eaſeth the toothach. For the falling downe of the Vvula, a gargariſme made of it with vinegre and honey, is excellent. There is not a medecine ſo ſingular for the ſtomacke and all the infirmities thereof, ne yet for the lungs. Being eaten at meat, it doth looſen ſuperfluous fleame, and cauſeth a man to reach and fetch it up with eaſe; yea and to take his wind and breath at libertie. In like manner, being taken warme with the juice of Cucumber, it cureth the falling ſickneſſe. It purifieth the ſenſes: it purgeth the head by ſmelling: it keepeth the body ſoluble: it pro- H
voketh womens monethly fleures, and urine. A cataplaſme made therewith and applied accordingly, helpeth them that be in a dropſie: ſo it doth thoſe that be ſubject to the falling ſickneſſe, but then muſt it be ſtamped with three parts of Cumin and figs. If it be tempered with vinegre and held to the noſe of ſuch women as with the riſing of the mother ſeeme to be ſtrangled and to lie in a traunce, it raiſeth them up againe: in like ſort, it awaketh thoſe who be in a fit of the lethargie: howbeit, in this caſe it is good to put thereto the ſeed of Seſeli of Candie, which they call Tordilion. But ſay that the Patients bee in ſo deepe a ſleepe in this drowſie diſeaſe, that by ſuch meanes they will not ſtart up and be raiſed; then take muſtard-ſeed and figgs, temper them with vinegre into a cataplaſme, apply the ſame to the *legs or the *forehead or region of the braine rather. It hath a cauſticke or burning qualitie, and being applyed in forme of a liniment I
to any part, it raiſeth pimples: by which means, it cureth the old inveterat pains of the breaſt, the ach of the loins, the haunch, and hucklebone, the ſhoulders, or any part of the bodie where need is that the offenſive humors ſetled deepe within, ſhould tranſpire and be drawne outwardly to an iſſue. Now for that the nature thereof is to bliſter, in caſe the Patient be timerous, and feare ſome extreame operation of that burning qualitie that it hath, it may be applied to the part affected between a doubled linnen cloth: otherwiſe, if the place be very thicke and hard, it would be laid too without any figs at all. Moreover, there is good uſe of Senvie with red earth, for to make the haire come againe which is falne; for ſcabs and ſcurfe, for foule morphew or the leproſie, the lowſie diſeaſe, the univerſall crampe that cauſeth the bodie to ſtand ſtiffe and ſtarke, as it were all of one peece without joynt; alſo the particular cricke which ſetteth the necke backward, that K
it cannot ſtir. An inunction made with it and honey, cureth the eyelids that be not ſmooth, but rugged and chapped; yea and clarifieth the eyes which be overcaſt with a muddie miſt.

ad revulſionem.
ad derivationem.

As touching the juice of Senvie, it is after three ſorts drawne: the firſt, being preſſed foorth, it is let to take a heat in the Sun gently by little and little, within an earthen pot. Secondly, there iſſueth forth of the ſmall ſtems or braunches that it hath, a white milkie liquor, which after it is dried and hardened in that manner, is a ſingular remedie for the tooth-ach. Where note by the way, that the ſeed & root both, after they have been well ſteeped and ſoked in new wine, are ſtamped or brayed together: now if one doe take in a ſupping as much of this juice thus drawne, as may be held in the ball of the hand; it is very good to ſtrengthen the throat and chaws, to fortifie the ſtomacke, to corroborat the eyes, to confirme the head, and generally to preſerve all the L
ſenſes in their entire. And verily I know not the like holeſome medicine againe, to ſhake off and cure the lazie and lither fevers that come by fits many times upon women. Senvie alſo being taken in drinke with vinegre, breaketh the ſtone and expelleth it by gravell. There is an oyle alſo made of muſtard-ſeed, infuſed and ſteeped in oyle, and ſo preſſed out; which is much uſed to heat and comfort the ſtiffeneſſe of ſinews occaſioned by cold: to warme alſo and bring into temper the through cold lying in the loins, haunches, and hucklebones, whereof commeth the Sciatica. Of the ſame nature and operation that Senvey is, Adarca is thought to be (according as I have touched in the diſcourſes of plants and trees growing wild in the woods;) which is a certein fomie ſubſtance ariſing and ſticking in the barke of certaine Canes, under their very leaves and tufts that they beare in the head. M

Concerning Horehound, which the Greekes call Praſion, others Linoſtrophon, ſome Philopes or Philochares, an hearbe ſo well knowne and ſo common, that it needs no deſcription; many Phyſicians have commended to be as medicinable as the beſt. And in truth, the leaves and ſeed both, being beaten into powder, are excellent good for the ſtinging of ſerpents, for the

paine

A paine of the breaſt and ſides, and ſingular for an old cough. Moreover, the juice is right ſoveraigne for thoſe who have their lungs periſhed and doe reach up bloud, if the braunches thereof gathered and bound up into bunches, be ſodden firſt in water with the graine called Panicke, for to mitigat in ſome ſort the unpleaſant harſhneſſe of the ſaid juice. A cataplaſme of Horehound applied unto the Kings evill with ſome convenient fat or greaſe, reſolveth the hard kernels. Some preſcribe a receit for the cough in this manner; Take the ſeed of greene Horehound as much as a man may comprehend with two fingers, ſeeth it with a ſmall handfull of the wheat called Far, putting thereto a little oile and ſalt, and ſo ſup off the decoction faſting Others hold, That without all compariſon there is not a medecine in the world like to the juice of Horehound and Fennell togither, firſt drawne by way of expreſſion to the quantitie of three ſextars, and afterwards
B boiled to the conſumption of a third part untill there remaine but two ſextars: then to this decoction there muſt bee put one ſextar of honey, and all ſodden againe to the conſumption of one third part more, unto the heigth of a ſyrup; whereof one ſpoonfull every day taken in a cyath of water, is a drinke that in this caſe hath no fellow. Horehound ſtamped and mixed with honey, is of wonderfull effect being applied to the privie parts of a man, for any griefes incident thereto. Laid with vinegre unto ringworms, tettars, and any ſuch running wildfires, it purgeth and riddeth them cleane away. A holeſome medecine it is to be applied as a cataplaſme, to ruptures, convulſions, ſpaſmes, and cramps of the ſinews. Taken in drinke with ſalt and vinegre, it eaſeth the belly and maketh it laxative. It provoketh womens tearms, and ſendeth out the after-birth. The powder of it drie, mixed with hony, is of exceeding great efficacie to ripen a drie cough, to cure gan-
C grenes, whitflaws, and wertwalls about the root of the nails. The juice dropped into the ears with honey, or ſnuffed up into the noſe, cureth their infirmities: it ſcoureth away the jaundiſe alſo and purgeth chollericke humours. And for all kind of poiſons, few hearbs are ſo effectuall as Horehound; for it ſelfe alone without any addition, cleanſeth the ſtomacke and breaſt, by reaching and fetching up the filthie and rotten fleame there engendred. If it be taken with honey and the floure-de-lis root, it provoketh urine. Howbeit, where there is daunger of any exulceration in kidneys or bladder, it muſt be uſed with great warineſſe, if it be uſed at all. Moreover, the juice of Horehound is ſaid to clarifie the eye-ſight. *Caſtor* putteth downe two ſorts of Horehound, to wit, the blacke and the white; but he ſetteth greater ſtore by the white than the other. He preſcribeth to take an emptie egg-ſhell, and to put into it the juice of Horehound and honey, by even portiD ons; and when the ſaid egg is warm, to miniſter the ſame by way of clyſtre or ſyringe, promiſing us, that the ſaid injection will breake all inward impoſtumes; and when they be broken, cleanſe and heale them throughly. Alſo a liniment (ſaith hee) made of Horehound ſtamped togither with old ſwines greaſe, cureth all wounds occaſioned by the biting of mad dogs.

Touching running Thyme, ſome thinke it is called Serpyllum in Latin, *à ſerpendo*, [*i.* of creeping] becauſe it runneth and creepeth by the ground: a propertie indeed of the wild kind, and eſpecially among rocks and ſtonie grounds. The garden Serpyllum, which commeth of ſeed, creepeth not, but groweth to the heigth of foure fingers breadth. The wild Thyme which commeth up of the owne accord, liketh and thriveth better, having whiter leaves and branches than the other: this (I ſay) is thought to have a ſpeciall vertue againſt ſerpents, and namely the CenE chris, the Scolopendres alſo as well of the ſea as the land; likewiſe the Scorpions, in caſe the ſprigs and leaves thereof be ſodden in wine, and ſo taken inwardly: If the ſame be burned, it yeeldeth a perfume, which with the very ſent chaſeth them all away. A ſingular power it hath againſt all venomous creatures of the ſea. Boiled in vinegre, and reduced into a liniment with oile of roſes, it cureth the head-ach, if it be applied as a frontall to the forehead and temples. In like manner it helpeth the phrenſie and lethargie: but if it be given to drinke, the weight onely of foure drams, it eaſeth the wrings & torments of the belly, it giveth free paſſage with eaſe to the urine, it reſolveth ſquinancie or bringeth them to maturitie, and ſtaieth vomits. And if one drinke it with water, it is excellent good for the opilation, heat, inflammations, and other accidents of the liver. The leaves, to the weight of foure Oboli, are given in vinegre, for the inflation and hardF neſſe of the ſplene. If it be beaten to powder and given in two cyaths of vinegre and honey, it is thought a good medecine for them that ſpit and reach up bloud.

The wild Siſymbrium or Creſſes, called of ſome Thymbræum, groweth to a foot in heigth and no higher. That which commeth up in waterie places, is like unto garden Creſſes: but both ſorts are effectuall againſt all pricks and ſtings of Hornets, and ſuch like creatures. That which

Some take it for water Mints or Horſemint.

ſpringeth up in drie ground, hath the narrower leafe of the twain, and carrieth a ſweet ſmell with it; whereupon it is commonly plaited among other odoriferous hearbs in chaplets and guirlands: But both the one and the other allayeth head-ach: likewiſe they doe ſtay the flux of waterish humors which diſtill into the eyes. Some put crums of bread thereto; others ſeeth them alone in wine, and uſe the decoction. Beeing reduced into a cataplaſme, and ſo applied everie night and taken off in the day time, it healeth within foure times laying on, the angrie chilblanes and bloudy-fals that trouble the feet in the night ſeaſon: yea and taketh away the ſpots and pimples ariſing in womens faces, which marreth their beautie, whether it be eaten with meat in ſubſtance, or the juice onely taken in drinke: it ſtayeth vomits, yexes, wringings, gnawings, and the diſſolution or feebleneſſe of the ſtomacke, which cauſeth inordinat flux. Women going with child muſt take heed how they eat Siſymbrium, unleſſe the fruit of their bodies bee dead within them; for if it be but applyed outwardly, it will ſend it forth. If one drinke it with wine, hee ſhall find that it provoketh urine: and the wild kind over and beſides, expelleth the ſtone and gravell. Such as had need to wake and watch, namely, thoſe that be given to drowſineſſe and lethargie, will be raiſed from their ſleepe and throughly wakened, if it be diſtilled aloft upon their heads with vinegre. G

Line-ſeed is employed with other matters in divers medecines to many uſes, but of it ſelfe alone it cleareth the skin of womens faces, taketh out ſpots, freckles, pimples, wems, and molls that be eye-ſores, if it be applied as a liniment thereto. The juice thereof quickeneth and helpeth the eyeſight. With Frankincenſe and water, or elſe with myrrhe and wine, it repreſſeth the violent flux of humors to the eyes. Reduced into a cataplaſme, with honey, greaſe, or wax, and ſo applied, it reſolveth the ſwelling kernels behind the ears. The meale thereof in manner of drie barley groats, if it be ſtrewed upon the ſtomacke, helpeth the weakneſſe and queaſineſſe thereof, which maketh it readie to overturne. If it be ſodden in water and oile, and ſo reduced into a liniment with Aniſe ſeed, and applied, it cureth the ſquinancie. It muſt be well dried and parched at the fire, in caſe it be given to ſtay the running out of the belly. As for thoſe that be troubled with the ſtomachicall flux, or the exulceration of the guts; a cataplaſme thereof with vinegre and ſo applied, bringeth them preſent eaſe. For the griefe of the liver, it ought to be eaten with raiſons. This ſeed is paſſing good for lohoches or electuaries to be made therof, in the cure of the Phthiſicke, and conſumption of the lungs. Lineſeed ground into floure and mingled with nitre or ſalt, or els with lie aſhes put thereto, is of great operation to mollifie the hardneſſe of muſcles, ſinews, joynts, and the nape or chine of the necke; yea and to mitigat the inflammations of the membrans or pellicles of the braine. The ſame applyed with figs, is an excellent maturative, and ripeneth all impoſtumes. But if it be laid too with the root of the wild Cucumber, it draweth forth any thing that ſticketh within the bodie, even the very ſpills and ſhivers of broken bones. The ſaid powder or flower made of Lineſeed ſodden in wine, and applied as a cataplaſme, ſtaieth cancerous ulcers that they run no farther: the ſame alſo with hony ripeneth apoſtemations of flegmaticke humors, and the breaking forth of the ſmall pocks. Being mingled with an equall portion of garden Creſſes, it cureth the rough nailes that grow untowardly, and fetcheth them off without any inconvenience. Incorporat with roſin and *myrrhe, and ſo laid to the cods, it helpeth their ſwelling and inflammations: it is good alſo for ruptures of all ſorts; and with water it healeth the Gangrene. Take of Lineſeed and Fenigreeke ſeed, of each one ſextar, ſeeth them in honeyed water, and make a liniment thereof, it eaſeth the paine of the ſtomacke. Lineſeed miniſtred in a clyſtre with oile and honey, cureth the deadly maladies of the guts and breaſt parts. H I K L

* *Murrha.*

Bleets ſeeme to be dull, unſavorie, and fooliſh Woorts, having no taſt nor quickneſſe at all: whereupon *Menander* the comicall Poet, bringeth in a husband upon the ſtage, who to reproch his wife for her ſottiſhneſſe and want of ſenſe, giveth her the tearme of Bleet. And in very truth, good it is for little or nothing, and altogither hurtfull unto the ſtomacke. It troubleth and diſquieteth the belly, inſomuch as it driveth ſome that uſe to eat it, into the daungerous diſeaſe Cholera, working both upward and downward without any ſtay. And yet ſome ſay, that if it be drunke in wine, it is good againſt Scorpions, and ſerveth for a pretie liniment to be applied unto the agnels or corns of the feet; yea and maketh a reaſonable good cataplaſme with oile, for the ſplene, and paine of the temples. Finally, *Hippocrates* is of opinion, that much feeding of Bleets, ſtaieth the monthly courſe of womens tearms. M

CHAP.

A

Chap. XXIII.

Of Meu, and Fenell, as well Gentle, named Fœniculum; as Wild, which is called Hippomarathrum, or Myrſineum: of Hempe, and Fenell-geant: and of Thiſtles and Artichoux.

MEu or Spicknell is not found in Italy, unleſſe it be in ſome Phyſicians garden, and thoſe are very few that ſow or ſet it. Howbeit, there be two kinds thereof: the one, which is the better, is commonly called Athamanticum, of Prince *Athamas* the firſt inventour of this hearbe, as ſome thinke; but according to other, becauſe the beſt Meu is found upon Athamas, a mountaine in Theſſaly. Leafed it is like to * Aniſe, riſing up with a ſtem otherwhile two cubits high; putting foorth many roots, and thoſe blackiſh, whereof ſome run very deepe into the ground: neither is this Meu ſo red altogither as the other. If the root thereof be beaten into powder, or otherwiſe ſodden and ſo drunke in water, it cauſeth urine to paſſe abundantly: in that order alſo it doth reſolve wonderfully the ventoſities gathered in the ſtomack. It aſſuageth mightily the wrings and torments of the guts: it openeth the obſtructions, and cureth other infirmities of the bladder and the matrice. Applyed with honey, it is very good for the joynts. Beeing laid as a cataplaſme with Parſley to the bottom of the belly of little children, it cauſeth them to make water.

B

* *Aniſo*, rather *Ariſtho*, Dill, after *Dioſcor.* whereupon it is called of ſome, wild Dill.

As for Fenell, the Serpents have woon it much credit, and brought it into name, in this regard, That by taſting thereof (as I have alreadie noted) they caſt their old skin, and by the juice that it yeeldeth doe cleare their eyes: whereby we alſo are come to know, that this hearb hath a ſingular * propertie to mundifie our ſight, and take away the filme or web that overcaſteth and dimmeth our eyes. Now the onely time to gather and draw the ſaid juice out of Fennell, is when the ſtalke beginneth to ſwell and wax big: which, after it is received, they uſe to drie in the Sun, and as need requireth, make an inunction with it and honey togither. There is of this juice to be had in all places: howbeit, the beſt is made in Iberia, partly of the gum that iſſueth or frieth (rather) out of the ſtalke [being brought neare to the fire;] or els drawne from the ſeed while it is freſh and greene. There is another making thereof out of the roots, by way of inciſion, preſently after that Fenell beginneth to ſpring and put foorth out of the ground, when winter is done.

C

* Such medicines be called ἐξυδερικὰ.

D There is another kind of wild Fenell, named by ſome Hippomarathrum, by others Myrſineum. Larger leaves this hath than that other of the Garden, and thoſe more ſharpe and biting at the tongues end: it groweth taller alſo, and ariſeth with a maine ſtem as big as a mans arme, & hath a white root. It groweth in hot grounds and thoſe that be ſtonie. *Diocles* maketh mention of another kind yet of wild Fenell, with a long and narrow leafe, bearing ſeed reſembling Coriander. As touching the garden Fenell, and the medicinable vertues that it hath, it is holden, That the ſeed, if it be taken inwardly in wine, is a ſoveraign drinke for the pricke of Scorpions or ſting of other Serpents. The juice thereof, if it be inſtilled by drops into the ears, killeth the worms there. The hearbe it ſelfe carrieth ſuch ſway in the kitchin, that lightly there is no meat ſeaſoned, nor any vinegre ſauce ſerved up without it. Moreover, for to give a commendable and pleaſant taſt unto

E bread, it is ordinarily put under the bottome-cruſt of our loaves, when they be ſet into the oven. The ſeed doth bind and corroborat a weake and feeble ſtomack, yea if it be taken in a very ague. Being beaten into powder and drunke in cold water, it ſtaieth the inordinat heaving of the ſtomacke, and the vaine proffers to vomit. For the lights and the liver, it is the moſt ſoveraign medecine of all other. Being taken moderatly, it ſtaieth the looſeneſſe of the belly, and yet provoketh urine. The decoction thereof appeaſeth the wrings of the guts: and taken in drinke, it filleth womens breaſts, and maketh them to ſtrout againe with milke, when it is gone upon ſome occaſion. The root taken in a Ptiſane of husked barly, purgeth the reins: ſo doth the ſyrrup made with the juice or decoction thereof; yea and the ſeed. The root ſodden in wine, is ſingular good for the dropſie and the crampe. A liniment made with the leaves and vinegre, and ſo applied, aſ-

F ſuageth hot ſwellings and inflammations: and the ſaid leaves have vertue to expell the ſtone of the bladder. Fenell taken inwardly any way, encreaſeth ſperme or naturall ſeed. A moſt friendly and comfortable hearbe it is to the * privie parts, whether it be by fomenting them with a decoction of the roots boyled in wine, or by applying a liniment unto them made with the ſaid roots ſtamped and incorporat with oile. Many doe make a cerot thereof with wax, for to lay unto tu-

* either ſwolne, exulcerat, or itching.

mours to places bruiſed and made black and blew with ſtripes. Alſo they uſe the root either prepared with the juice of the hearb, or otherwiſe incorporat with honey, againſt the biting of dogs: and taken in wine, againſt the worme called Milleped. But for all theſe purpoſes beforeſaid, the wild Fennell is of greater operation than the garden Fennell: but this principall vertue it hath, mightily to expell the ſtone and gravell. If it bee taken with any mild and ſmall wine, it is very good for the Bladder, [and namely the Strangurie] alſo it provoketh womens tearmes that bee either ſuppreſſed or come not kindly away: to which purpoſe the ſeed is more effectuall than the root. But whether it bee root or ſeed, it would bee uſed in a meane and meaſure: for it is thought ſufficient to put into drinke at once, as much as two fingers will take up. *Petridius*, who wrote the booke entituled *Ophiaca, and *Myction* likewiſe in his Treatiſe named *Rhizotorumena, were of opinion, That there is not a better countrepoyſon againſt the venome of Serpents, than wild Fennell. And certes, *Nicander* himſelfe hath raunged it, not in the loweſt place of ſuch medicines.

*Of Serpents.
*Of cutting up or gathering roots.

Concerning Hempe, at firſt it came up without ſowing even in the very woods, and caried a more duskiſh greene leafe, and the ſame rougher. It is ſaid, that if men eat the ſeed, it will extinguiſh utterly their own ſeed. The juice of greene Hempe-ſeed, being dropped into the ears, driveth out any wormes or vermin there engendred, yea, and what earewigs or ſuch like creatures that are gotten into them: but it will cauſe head-ach withall. So forcible is this plant, that (by report) if it bee put into water, it will make it to gather and coagulat. Which is the reaſon, that if horſes have the gurrie, they ſhall find helpe by drinking the ſaid water. The root if it bee boiled in water, doth mollifie and ſoften joints that be ſhrunke up: it aſſuageth the paines likewiſe of the Gout, and ſuch like wicked humors that fall downe upon any part. Being yet greene and reduced into a liniment and ſo applied, it is good for burns or ſcaldings, but it muſt bee often remooved and chaunged before it be drie.

As for Ferula or Fennel-geant, it carieth a ſeed like to Dill. That kind which riſeth up in one ſtem, and then devideth it ſelfe and braunceth forth in the head, is ſuppoſed to bee the female. The ſtalkes are good to be eaten boiled: and the right ſauce wherein they bee ſerved up, to give them a more commendable taſt, is new wine and honey tempered accordingly; and ſo prepared, they bee good for the ſtomacke. Howbeit, if one eat over-liberally of them, they cauſe head-ach. Take the weight of one denier Romane of the root, beat it to pouder and drinke it in two cyaths of wine, you ſhall find it a ſoveraigne medicine againſt the ſtinging of Serpents: but you muſt not forget mean while to applie the root it ſelfe (ſtamped into a cataplaſme) unto the hurt place. After this manner it helpeth the wringing torments of the guts. Make a liniment or unguent thereof and vinegre together, annoint the bodie therewith; it reſtraineth the immoderat ſweats that burſt out, although the patient bee ſicke of a fever. The juice of Ferula, if it be eaten (to the quantitie of a Beane) doth looſen the bellie. The ſmall tendrils or braunches of greene Ferula, is good for all the infirmities abovenamed. Take tenne graines of Ferula ſeed in pouder with wine, or ſo much of the pith within the ſtalke, it ſtancheth bloud. Some hold it good to give a ſpoonefull thereof every fourth, ſixth, and ſeventh day after the change of the Moone, to prevent the fits of the falling ſicknes. The nature of all theſe Fennell geants is moſt adverſe to Lampreies, for if they be touched never ſo little therewith, they will die upon it. *Caſtor* was of opinion, That the juice is excellent good to cleare the eyeſight.

And for as much as I have ſpoken ſomewhat of Thiſtles and Artichoux (how they ſhould be ordered) in my treatiſe of other garden plants, I will put off no longer to diſcourſe alſo of their properties and vertues in Phyſicke. Of the wild Thiſtles there be two kinds: the one more full of braunches, ſhutting out immediatly from the root; the other riſeth up in one entire ſtem, and the ſame is thicker withall. Both of them have but few leaves, and thoſe beſet with prickles: they beare heads pointed with ſharpe prickes round about in manner of caltrops. Howbeit, there is one kind, which is the Artichoke, which putteth forth a purple flower amid thoſe ſharpe pointed prickes, which very quickly turns into an hoarie downe, readie to flie away with every puffe of wind: and this Thiſtle the Greeks call Scolymos. The juice of the Artichoke ſtamped and preſſed out before it bloume, bringeth haire againe thicke, if the naked place bee annointed therewith. The root either of Thiſtle or Artichoke, ſodden in water and ſo eaten, is as good as a ſhooing-horne to draw on pot after pot, for theſe great bibbers that deſire nothing more than to be thirſtie and to make quarell to the cup. It ſtrengtheneth the ſtomacke, and (if wee may beleeve it) is

ſo

A ſo appropriat unto the matrice of women, that it diſpoſeth & prepareth it to conceive men children. In good faith *Chæreas* the Athenian and *Glaucias* eſpecially, who ſeemeth to be moſt curious in deſcribing the nature and properties of theſe Thiſtles or Artichokes, give out no leſſe. To conclude, if one chew them in his mouth, hee ſhall find that they will cauſe a ſweet breath.

Chap. xxiiii.

The compoſition of a Treacle, which was the ordinarie and familiar medicine of king Antiochus.

B BVt before that wee goe out of the garden, and leave the hearbes there growing, I thinke it good to ſet downe one confection made of them; thought to be a moſt excellent and ſoverajgne Antidote or preſervative againſt the poyſon of all venomous beaſts whatſoever: and which for the excellencie thereof was engraven in ſtone upon the forefront of the temple dedicated to *Æſculapius*, in this manner following: Take of wild running Thyme, the weight of two deniers; of Opopanax and *Meu, of each the like quantitie; the ſeeds of Dill, Fennell, Ameos, and Perſeley, of each the weight of ſix deniers; of Ervill floure twelve deniers or drams. Let theſe bee beaten into pouder, and finely ſearced: and when they bee incorporat in the beſt wine that may bee had, they ought to bee reduced into the forme of Troſches, every one weighing a victoriat or halfe denier. When occaſion is to uſe this compoſition, diſſolve one of theſe Troſches in three cyaths of wine, and drink it. This is that famous Treacle or countrepoyſon, which great C *Antiochus* the king was wont (by report) to take againſt all venomes or poyſons whatſoever.

*Mei, non Mili. Ex Galen.

D THE XXI. BOOKE OF THE HISTORIE OF NATVRE, WRITTEN BY C. PLINIVS SECVNDVS.

The nature of Flowers, and namely thoſe of Chaplets and Guirlands. E

Chap. i.

The wonderfull varietie of Flowers.

F CAto in his Treatiſe of Gardens, ordained as a neceſſary point, That they ſhould be planted and enriched with ſuch hearbes as might bring foorth flowers for Coronets and Guirlands. And in very truth, their diverſitie is ſuch, that unpoſſible it is to decipher and expreſſe them accordingly. Wherby we may ſee that more eaſie it was for dame Nature to depaint and adorne the earth with ſundrie pictures, to beautifie the fields (I ſay) with all manner of colors, by her handie work (eſpecially where ſhe hath met with a ground to her mind, and when ſhe is in a merrie humor and diſpoſed to play and diſport her ſelfe) than for any man in the world to utter the ſame by word of mouth. Wherein certes her admirable providence ſhe hath ſhewed, principally in

in this, That whereas ſhe hath given unto thoſe fruits of the earth which ſerve for neceſſities and G
the ſuſtentation of man, long life and a kind of perpetuitie, even to laſt yeares, and hundreds of yeares; theſe flowers of pleaſure and delight, good only to content the eye or pleaſe the ſence of ſmelling, ſhee would have to live and die in one day. A great document and leſſon for us men in generall to learne, How all things whatſoever that flouriſh moſt lovely and be gaieſt in ſhew, ſooneſt fade and are gone ſuddainely. But to come againe to the varietie of flowers aforeſaid, together with their divers mixtures: verely there is no painter with all his skill able ſufficiently with his penſill to repreſent one lively guirland of flowers indeed; whether they bee plaited and intermedled in manner of noſegaies one with another, or ſet in rankes and rewes one by another; whether they bee knit and twiſted cordwiſe and in chaine-worke of one ſort of flowers, either to wind and wreath about a chaplet, bias, or in faſhion of a circle, or whether they bee ſorted round H
into a globe or ball, running one through another, to exhibite one goodly ſight and entire uniformitie of a croſſe Garland.

Chap. II.

Of Guirlands, Coronets, Chaplets, and Noſegaies made of floures. Who deviſed firſt the ſorting and ſetting of ſundrie flowers. The firſt invention of the Coronet or Guirland, and the name of it in Latine, Corollæ, and wherupon it was ſo called.

THe Coronets or Guirlands uſed in auncient time, were twiſted very ſmall, and thereupon I
they were called Strophia, *i.* Wreaths: from whence came alſo womens gorgets and ſtomachers to be named Strophiola. As for the word Corona, a Coronet or Guirland, long it was firſt ere it came to bee vulgar and commonly taken up, as a tearme challenged either by prieſts and ſacrificers in their divine ſervice, or victorious captaines in their glorious triumphes. But thoſe Guirlands or Noſegaies being made of flowers, were called in Latine Serta or Serviæ *à ſerendo, i.* of ſorting and ſetling together. The manner of which plaiting and broiding of heatbs and flowers, the auncient Greekes tooke no pleaſure in: for at the beginning they uſed to crowne with branches onely of trees, thoſe brave men who had woon the priſe in their ſacred Games and ſolemne Tournois or exerciſes of activitie. But afterwards they began to beautifie and enrich their chaplets of triumph with ſundrie flowers intermingled together. And (to ſay a truth) the Si- K
cyonians paſſed in this feat of ſorting together one with another flowers of ſweet ſavor and pleaſant colour, in making of poſies & guirlands. Howbeit, the example of *Pauſias* the cunning painter, and *Glycera* the artificiall maker of ſuch chaplets, ſet them firſt a worke. This painter was wonderfully enamoured upon the ſaid *Glycera*, and courted her by all meanes that hee could deviſe: among the reſt, he would ſeem to counterfeit and repreſent lively with his penſill in colours, what flowers ſoever ſhe wrought and ſet with her fingers into Guirlands; and ſhee againe ſtrived avie to chaunge and alter her handy work every day, for to drive him to a non-plus at the length, or at leaſtwiſe, to put him to his ſhifts: in ſo much, as it was a verie pleaſant and woorthie ſight, to behold of one ſide the workes of Nature in the womans hand, and on the other ſide the artificiall cunning of the foreſaid painter. And verely there are at this day to bee ſeene diverſe L
painted Tables of his workmanſhip: and namely, one picture above the reſt, entituled *Stephanoplocos, wherein he painted his ſweet heart *Glycera*, twiſting and braiding Coronets and Chaplets, as her manner was. And this fell out to be, after the hundreth Olympias was come and gone by juſt account.

*A Garland-maker.

Now when theſe Guirlands of flowers were taken up and received commonly in all places for a certaine time, there came ſoone after into requeſt thoſe Chaplets which are named Ægyptian, and after them Winter Coronets, to wit, when the earth affourdeth no flowers to make them; and thoſe conſiſted of home ſhavings, died into ſundrie colours. And ſo in proceſſe of time, by little and little, crept into Rome alſo the name of Corollæ, as one would ſay, Pettie Guirlands; for that theſe Winter Chaplets at firſt were ſo prettie and ſmall: and not long after M
them, the coſtly Coronets and attires Corollaria, namely, when they were made of thin leaves and plates of Latton, either guilded or ſilvered over, or elſe ſet out with golden and ſilver ſpangles, and ſo preſented.

Chap.

Chap. iii.

Who was the first that exhibited in publicke shew a Guirland or Chaplet of gold and silver-foile. How highly Coronets were esteemed in old time. Of the honour done to Scipio. Of plaited Coronets. And one notable Act of Queene Cleopatra.

Crassus the rich was the first man, who at the solemne Games and Plaies which he set out in Rome, gave away in a brave shew, Chaplets of gold and silver, resembling lively flowers and leaves of hearbes. Afterwards, such Coronets were adorned with ribbands also, and those were added as pendants thereto for more honour and state: a devise respective to those *Tuscane Guirlands and Coronets, which might have no such ribbands or laces hanging unto them but of gold. And in truth those labels a long time were plaine and without any other setting forth save onely the bare gold: untill *P. Claudius Pulcher* came in place, who exhibited in his publicke shewes, the said labels wrought, chased, and engraven; yea, and hee garnished the said plates of gold with glittering and twinckling spangles besides. Howbeit, were these Coronets never so rich and precious, yet those Chaplets woon and gotten at the solemne Games for some worthie feats of activitie performed, caried alwaies the greater credit & authoritie. For to gaine this prise, the Grand-siegniors and great men of the citie thought it no scorne to enter themselves in proper person into the publicke place of Exercise to trie maistries: yea, and thither they sent every man his servant and slave. Hereupon grew these Ordinances, specified among the laws of the twelve Tables in these words: *Whosoever winneth a Guirland, either himselfe in person, or by his monie, goods and chattels, is to be honored in regard of his vertue.* And certes who maketh doubt, but what Prise or Coronet either slaves or horses have obtained, the same by vertue of this law, should be reputed as gotten by the money and goods of the maister or owner of the said horses or slaves? But what honour might this be which is thus atchieved by such a Chaplet? Mary that which is right great, namely, That without all fraud and contradiction, not onely the partie himselfe who woon it, should be crowned therewith after his death, both whiles his bodie lay under bourd within house, and also all the way that it was caried forth to the place of sepulture or funerall fire; but even his parents likewise, both father and mother [if they were then living.] Certes, such Guirlands otherwise though they were not woon at games of prize, but only made for pleasure and pastime, might not come abroad ordinarily, nor bee commonly worne; for the law was very strict and severe in this case. We read that *L. Fulvius Argentarius* in the time of the second Punicke warre, upon an information or speech given out, That in the open day time he only looked forth of a gallerie which he had in the publicke Forum or common place at Rome, with a Garland of Roses upon his head; was by authoritie of the Senate committed to prison, and was not enlarged before the end of the warre. *P. Munatius* having taken from the head of *Marsyas* a Chaplet of flowers, and set it upon his owne; and thereupon beeing commaunded to ward, by the Triumvirs, called unto the Tribunes of the Commons for their lawfull favour and protection: but they opposed not themselves against this proceeding, but deemed him woorthie of this chastisement. See the discipline and severitie at Rome, and compare it with the looseneſſe of the Athenians, where young youths ordinarily followed revels and bankets, and yet in the forenoon would seeme to frequent the schooles of Philosophers, to learne good instructions of vertuous life. With us verily we have no example of disorder in this behalfe, namely, for the abuse of Garlands; but onely the daughter of *Augustus Cæsar* late Emperor, and canonised as a god at Rome, who complaineth of her in some letters of his yet extant, and that with grone and greefe of hart, to be given to such roiot and licentious looseneſſe, that night by night she would seeme to adorn with Guirlands the statue and image of *Marsyas* the Minstrell. Wee doe not read in Chronicles, that the people honoured in old time any other with a Coronet of flowers, but onely *Scipio* surnamed *Serapio*, for the neare resemblance that he had to his baylie or servant so called, who dealt under him in buying and selling of Swine: in which regard he was wonderous well beloved of the Commons in his Tribuneship, as bearing himselfe worthie of the famous and noble house of the *Scipioes* surnamed *Africani*. Howbeit, as well descended and beloved as he was, yet when he died, he left not behind him in goods sufficient to defray the charges of his funerals. The people therefore made a collection, and contributed by the poll every man one *As: and so tooke order by

*These Guirlands or Chaplets were called *Hetruscæ*. For so saith *Tertullian. Præferuntur etiam illis Hetruscæ. Hoc vocabulum est Coronarii, &c.* i. to be Ædile.

*i. three farthings.

by a generall expence, that he ſhould be honourably enterred: and as his corpes was carried in G
the ſtreets to his funerall fire, they flung flowers upon his bere out of every window all the way. In
thoſe daies the manner was to honour the gods with Chaplets of flowers, and namely thoſe that
were counted patrones and protectours, as well of citties and countries, as of privat families; to
adorne and beautifie therewith the tombes and ſepulchres of thoſe that were departed, as alſo to
pacifie their ghoſts, and other infernall ſpirits: farther than thus, there was no uſe of ſuch Guir-
lands allowed. Now of all thoſe Chaplets, moſt account was made of them wherein the flowers
were platted. We find moreover, That the Sacrificers or Prieſts of *Mars* called *Salij*, were wont
in their ſolemnities and feaſts (which were very ſumptuous) to weare Coronets of ſundrie flowers
ſowed together. But afterwards, Chaplets of Roſes were onely in credit and reputation: untill
that in proceſſe of time, the world grew to ſuch ſuperfluitie and ſumptuous expence, that no H
Guirlands would pleaſe men, but of the meere pretious and aromaticall leafe Malabathrum: and
not content herewith, ſoone after there muſt be Chaplets fet from as farre as India, yea, and be-
yond the Indians, & thoſe wrought with needle work. And the richeſt Coronet was that thought
to be, which conſiſted of the leaves of Nard: or els made of fine ſilke out of the Seres countrey,
and thoſe of ſundrie colours, perfumed beſides & all wet with coſtly and odoriferous ointments.
Further than thus they could not proceed: and ſo our daintie wanton dames reſt contented hi-
therto, and uſe no other Chaplets at this day. As for the Greekes verely, they have written alſo
ſeverall Treatiſes concerning flowers and Garlands: and namely, *Mneſtheus* and *Callimachus*,
two renowmed Phyſicians, have compiled bookes of thoſe Chaplets that be hurtfull to the brain
and cauſe head-ach. For even herein alſo lieth ſome part of the preſervation of our health, con- I
ſidering that perfumes do refreſh our ſpirits, eſpecially when we are ſet at table to drinke liberal-
ly and to make merrie, whiles the ſubtile odour of flowers doth pierce to the braine ſecretly ere
we bee aware. Where, by the way, I cannot chuſe but remember the deviſe of Queene *Cleopatra*,
full of fine wit, and as wicked and miſcheevous withall: For at what time as *Antonie* prepared
the expedition and journey of Actium againſt *Auguſtus*, and ſtood in ſome doubt and jealouſie
of the ſaid Queen; for all the faire ſhew that ſhe made of gratifying him and doing him all plea-
ſure, he was at his taſter, and would neither eat nor drinke at her table without aſſay made. *Cleopa-
tra* ſeeing how timorous he was, and minding yet to make good ſport and game at his needleſſe
feare and fooliſh curioſitie, cauſed a Chaplet to bee made for *M. Antonius*, having before dipped
all the tips and edges of the flowers that went to it in a ſtrong and ranke poyſon, and beeing thus K
prepared, ſet it upon the head of the ſaid *Antonie*. Now, when they had ſitten at meat a good
while, and drunke themſelves merrie, the Queen began to make a motion and challenge to *An-
tonie*, for to drinke each of them their Chaplets; and withall began unto him in a cup of wine ſea-
ſoned and ſpiced (as it were) with thoſe flowers which ſhe ware her owne ſelfe. Oh the ſhrewd and
unhappie wit of a woman when ſhe is ſo diſpoſed! who would ever have miſdoubted any danger
of hidden miſcheefe herein? Well, *M. Antonie* yeelded to pledge her: off goeth his own Guir-
land, and with the flowers minced ſmall, dreſſeth his owne cup. Now when he was about to ſet it
to his head, *Cleopatra* preſently put her hand betweene, and ſtaied him from drinking, and with-
all uttered theſe words, My deere heart and beſt beloved *Antonie*, now ſee what ſhee is whom ſo
much thou doeſt dread and ſtand in feare of, that for thy ſecuritie there muſt wait at thy cup and L
trencher extraordinarie taſters; a ſtrange and new faſhion ywis, and a curioſitie more nice than
needfull: lo, how I am not to ſeeke of means and opportunities to compaſſe thy death, if I could
find in my heart to live without thee. Which ſaid, ſhe called for a priſoner immediatly out of the
Goale, whom ſhe cauſed to drinke off the wine which *Antonie* had prepared for himſelfe. No ſoo-
ner was the goblet from his lips againe, but the poore wretch died preſently in the place. But to
come againe to the Phyſicians who have written of flowers beſides thoſe abovenamed. *Theo-
phraſtus* among the Greekes hath taken this argument in hand. As for our countreymen, ſome
*Of flower gathering. have entituled their bookes *Anthologicon: but none of them all, ſo farre as ever I could find,
wrote any Treatiſe concerning flowers. Neither is it any part of my meaning at this preſent to
make Noſegaies, or plat any Chaplets, for that were a frivolous and vaine peece of worke: but as M
touching flowers themſelves, I purpoſe to diſcourſe ſo much as I thinke and find to bee memora-
ble and worth the penning. But before I enter into this Treatiſe, I am to advertiſe the Reader that
we Romanes are acquainted with very few garden flowers for Guirlands, and know in manner
none but Violets and Roſes.

CHAP.

A

Chap. iiii.

Of the Roſe emploied in Coronets. The diverſe kinds thereof: and where it is ſet and groweth.

THe plant whereupon the Roſe dooth grow, is more like a thorne or buſh than a ſhrub or any thing elſe. For it will come of a very brier or Eglantine alſo, where it will caſt a ſweet and pleaſant ſmell, although it reach not farre off. All Roſes at their firſt knitting ſeeme to bee encloſed within a certaine cod or huske full of graines: which ſoone after beginneth to ſwell and grow ſharpe pointed into certaine greene endented or cut buds: then by little and little as
B they wax red, they open and ſpread themſelves abroad, containing in the middeſt of their cup as it were, certaine ſmall tuffets or yellow threads ſtanding out in the top. * Vſed they are exceeding much in Chaplets and Guirlands. As touching the oile Roſat, made by way of infuſion, it was in requeſt before the deſtruction of Troy, as may appeare by the Poet *Homer*. Moreover, Roſes enter into the compoſition of ſweet ointments and perfumes. Over and beſides, the Roſe of it ſelfe alone as it is, hath medicinable vertues, and ſerveth to many purpoſes in Phyſick. It goeth into emplaſters and collyries or eyeſalves, by reaſon of a certain ſubtile mordacitie and penetrative qualitie that it hath. Furthermore, many delicats and daintie diſhes are ſerved up to the table, either covered and beſtrewed with Roſe leaves, or bedewed and ſmeared all over with their juice; which doth no harme to ſuch viands, but give a commendable taſt thereto. Wee at
C Rome make moſt account of two kinds of Roſes above the reſt, to wit, thoſe of Prænеſte, and of Capua. And yet ſome have raunged with theſe principall Roſes, thoſe of Miletum, which are of a moſt lively and deepe red colour, and have but twelve leaves in a flower at the moſt. The next to them are the Trachinian Roſes, not ſo red all out. Then thoſe of Alabanda, which bee of a baſer reckoning, with a weake colour enclining to white. Howbeit the meaneſt and worſt of all, is the Roſe *Spineola. Moſt leaves in number it hath of all others, and thoſe in quantitie ſmaller. For this would be known, that Roſes differ one from another either in number of leaves, more or leſſe;
D or els that ſome be ſmooth, others rough and prickie: alſo in colour, and ſmell. The feweſt leaves that a Roſe hath, be five: and ſo upward they grow ever ſtill more and more, untill they come to thoſe that have a hundred, namely about Campaine in Italie, and neare to Philippos a cittie in Greece, whereupon the Roſe is called in Latine Centifolia. Howbeit, the territorie of Philippi hath no ſuch ſoile as to bring forth theſe hundred-leafe Roſes: for it is the mountaine Pangæus neare adjoining, upon which they naturally do grow, with a number of leaves I ſay, but the ſame ſmall: which being removed and tranſplanted by the neighbour borderers, doe mightily thrive in another ground, namely, about Philippi aforeſaid, and prove much fairer than thoſe of Pangæus. Yet are not ſuch Roſes of the ſweeteſt kind, that are ſo double and double again; no more than thoſe which are furniſhed with the largeſt & greateſt leaves. But in one word, if you would know a ſweet ſmelling Roſe indeed, chuſe that which hath the cup or knob underneath the flour, rough, and prickie. *Cæpio* who lived in the time of *Tiberius* the Emperour, was of opinion, That the hundred-leafe Roſe had no grace at all in a Guirland, either for ſmell or beautie; and therfore
E ſhould not be put into Chaplets, unleſſe it were laſt in manner of a tuft, to make a ſur-croiſt, or about the edges as a border: no more than the Roſe Campion, which our men call the Greeke Roſe, and the Greekes name Lychnis, which lightly groweth not but in moiſt grounds, and never hath more than five leaves; the flower exceedeth not the bigneſſe of a certaine Violet, and carieth no ſent or ſavour at all. Yet is there another Roſe named Græcula: the flowers & leaves wherof are folded and lapped one within another, neither will they open of themſelves, unleſſe they be forced with ones fingers, but looke alwaies as if they were in the bud, notwithſtanding, that the leaves when they be out, are of all others largeſt. Moreover, there be Roſes growing from a buſh that hath a ſtalke like a Mallow, and beareth leaves reſembling thoſe of the Olive: and this kind is named in Greeke Moſcheúton. Of a middle aſſiſe betweene theſe abovenamed, is the Roſe of
F Autumne, commonly called Coroneola. And to ſay a truth, all the ſaid Roſes, unleſſe it bee this Coroneola, and that which groweth upon the brier or Eglantine beforenamed, have no ſmell with them in the whole world naturally, but are brought to it by many deviſes and ſophiſtications: yea, & the very Roſe it ſelfe, which of the owne nature is odoriferous, carieth a better ſmell in ſome one ſoile than in another. For at Cyrene they paſſe all other for ſweetneſſe and pleaſant ſavour;

*Vſus eius propè nimius eſt.

*Our white Roſe.

ſavour: which is the reaſon, that the oile Roſat, and ointment compounded thereof, is moſt excellent there of all other places. And at Carthagena in Spaine there bee certaine timely or haſtie Roſes that blow and floure all Winter long. The climat alſo and temperature of the aire maketh for the ſweetneſſe of the Roſe: for in ſome yeares yee ſhall have them leſſe odoriferous than in others. Over and beſides, the place would be conſidered: for the Roſes be ever more ſweet growing upon drie than wet grounds. And indeed the Roſe buſh loveth not to be planted in a fat and rich ſoile, ne yet upon a veine of cley, no more than it liketh to grow neare unto rivers where the bankes be overflowed, or in a wateriſh plot; but it agreeth beſt with a light & looſe kind of earth, and principally with a ground full of rubbiſh, and among the ruins of old houſes. The Campain Roſe bloweth earely, and is very forward. The Mileſian commeth as late. Howbeit, thoſe of Præneſte bee longeſt ere they give over bearing. As touching the manner of planting them: as the ground would bee delved deeper than for corne, ſo a lighter ſtitch had need bee taken than for Vine ſets. Thoſe that be ſowed of ſeed, bee lateſt of all others ere they come up, and thrive moſt ſlowly. [Now lieth this ſeed in the cup or huske thereof juſt under the very flower, and is covered all over with a downe.] And therefore it is better to ſet ſions cut from the ſtalke, or els to ſlip the little oilets and ſhoots from the root, as the manner is in reeds & canes. After which ſort they uſe to ſet, yea, and to graffe one kind of a prickie & pale Roſe-buſh, putting forth very long twigs and ſhoots like to thoſe of the Cinq-foile Roſe, which is one of the Greekiſh kind. There is no Roſe-buſh whatſoever, but proſpereth the better for cutting, pruning, yea and burning. Moreover, it loveth to be removed and tranſplanted as well as the Vine, and by that meanes will it ſoon come to the proofe and beare beſt. As for the ſets or ſions, they ought to be foure fingers long or more above the ground, when they be firſt put into the earth, to wit, after the occultation of the Brood-hen ſtar. Then would they bee tranſlated in Februarie, at what time as the Weſterne wind Favonius is aloft, and replanted with a foot diſtance one from another: but they require to be ever and anone digged about the root. They that deſire to have Roſes blow betimes in the yeare, before their neighbours, uſe to make a trench round about the root, a foot deepe, and poure hote water into it, even at the firſt when the bud of the Roſe beginneth to be knotted.

G H I

Chap. V.

Of Lillies three kinds: and the manner of planting or ſetting them.

NExt to the Roſe, there is not a fairer flower than the Lillie, nor of greater eſtimation. The oiles alſo and ointments made of them both, have a reſemblance and affinitie one to the other. As touching the oile of Lillies, the Phyſicians call it Lirinon. And if a man ſhould ſpeake truly, a Lillie growing among Roſes, becommeth and beautifieth the place very well; for it beginneth then to flower when Roſes have halfe done. There is not a flower in the garden again that groweth taller than the Lillie, reaching otherwhile to the heigth of three cubits from the ground: but a weake and ſlender necke it hath, and carrieth it not ſtreight and upright, but it bendeth and noddeth downeward, as being not of ſtrength ſufficient to beare the weight of the head ſtanding upon it. The flower is of incomparable whitenes, devided into leaves, which without-forth are chamfered, narrow at the bottome, and by little and little ſpreading broader toward the top: faſhioned all together in manner of a broad mouthed cup or beaker, the brims and lips whereof turne up ſomewhat backeward round about and lie very open. Within theſe leaves there appeare certaine fine threds in manner of ſeeds: and juſt in the middeſt ſtand yellow chives, like as in Saffron. As the colour of the Lillie is two-fold, ſo carieth it a double ſmell; one in the leaves which reſembleth the cup aforeſaid, and another in thoſe ſtrings or chives; how beit the difference is not much. Now for to make the oile and ointment of Lillies, the leaves alſo are not rejected.

K L

There is an hearbe named in Latine Convolvulus [*i.* Withwind] growing among ſhrubs and buſhes; which carrieth a flower not unlike to this Lillie, ſave that it yeeldeth no ſmell, nor hath thoſe chives within: for whitenes they reſemble one another very much; as if Nature in making this flower, were a learning and trying her skill how to frame the Lillie indeed.

M

Now Lillies be ſet and ſowed after the ſame manner in all reſpects as the roſes, and grow as many waies. This vantage moreover they have of the roſes, That they will come up of the very liquor that diſtilleth and droppeth from them, like as the hearb Aliſanders: neither is there in

the

A the world an heath more fruitfull, insomuch as you shall have one head of a root put forth oftentimes five hundred bulbs or cloves.

There is besides, a red Lillie, which the Greeks in their language call Crinon; and some name the floure of it Cynorrhodon. The excellent Lillie of this kind groweth in Antiochia and Laodicea, cities both in Syria: the next to that is found in Phaselis. In a fourth place, is to be set the Lillie growing in Italy. There are besides, purple Lillies, which otherwhiles rise up with a double stem: these differ from the rest onely in the pulpous root which they have; and the same carrie a greater bulbe in one entire head, and no more: such they call Daffodils. A second sort there is of these Daffodils, with a white floure, and a purple cup or bell within. Herein differ Daffodils from Lillies, For that the Daffodill leaves be toward the root, & namely those in the best mountains of Lycia; whereas in Lillies they put forth in the stalke. The third kind agreeth in all points B with the rest, but that the cup in the mids of the floure is of a grasse green. But all the sort of them be late ere they floure; and begin not to blow before the rising of the star Arcturus, and about the Autumne Æquinox. But such are the monstrous devises of some fantasticall spirits, that they invented forsooth a new kind of artificiall * colouring and dying of Lillies: for which purpose, in the moneth of Iuly they gather their stems, when they begin to wither, and hang them up in the smoke to drie. Now when the knobs or heads of their roots looke once bare and are shot out from the said stalks, (which commonly falleth out in the month of March) they infuse & steepe them in the lees of deepe red wine, or some Greekish wine, for to sucke and drinke in the colour thereof: which done, they set them in little trenches, whereinto they poure certaine hemines or C pints of the said wine: and by this means become the Lillies aforesaid, purple. A straunge and wonderfull matter, that any root should take a tincture so deepe, as to bring forth a floure of the same die and colour.

* *Insidendi.*

CHAP. VI.

Of the Violet and the Marygold: of Bacchar, and Combretum: of Asara-Bacca, and Saffron.

IN the third ranke of floures, bee raunged the * Violets; whereof be many kinds: to wit, the purple, the yellow, and the white. All of them may be set of plants, like as woorts and garden D pot-hearbs. But of those which naturally come up and grow of their owne accord in leane grounds, and those exposed to the Sun, the purple [March] Violets, they have a broader leafe than the rest, and those spring immediatly from the root, which is pulpous and fleshie. These alone be distinct from the rest by a Greeke name, and are called * Ia; whereupon purple cloth is likewise of them named Ianthina. But of those which are sowne or set by hand, the * yellow beare the greatest name above all other. These floures be distinguished into divers kinds, namely, into the Tusculan Violets; and those of the Sea, which have a broader leafe but are not so sweet as others. Some smell not at all, to wit, the * Calathian Violet with the small leafe: a floure this is that Autumne yeeldeth, whereas the rest doe flourish in the Spring.

* Note that *Viola* in *Plinie* and other authors, reacheth to our Stocke-gillofres, walflours, & other flours, as to the purple March Violet.

* Ἰὰ ἑστὸν ἰῶ.

* *Cheiri*, or Wall flours.

Next unto the Violet, are the Marigolds, all of one colour. In number of leaves this floure E passeth the Sea-violet aforesaid, which never exceedeth five: but in recompence of that defect, this Violet goeth beyond the Marigold in sweet savour, for the Marigold carrieth a strong sent with it and an unpleasant. As for the hearb called * Scopa regia, it hath a smell nothing milder than it; although the leaves (to say a truth) doe smell, and not the floures.

* Some take it for a kind of Fox-glove.

* Which some take for yellow Yarrow.

Bacchar is named by some Rustick-Nard: this plant hath nothing in it odoriferous and fenting well, but the root. Of which root (as *Aristophanes* an auncient Comicall Poët testifieth in one of his Comœdies) they were woont in old time to make sweet perfumes and odoriferous compositions for their ointments: whereupon some there be who call the root Barbarica, but falsly; for deceived they are. The savour that this root doth cast, draweth very neare to the sent of Cinamon. It loveth a leane and light soile, and in no wise commeth up in a moist ground.

F As touching the hearb named Combretum, it resembleth the same very much; howbeit the leaves be passing small and as slender as threads, but the plant it selfe is taller than Bacchar. Wel, rest we must not in the description of these hearbs and floures onely, but also wee are to reforme and correct their error, who have given to Bacchar the name of Nard-Rustick: For there is another hearb properly so called, to wit, that which the Greekes name Asaron, [*i.* Asara-Bacca, or

Fole-foot;] a plant far different from Bacchar, as may appeare by the deſcription therof, which I have ſet downe among the ſundrie kinds of Nardus. And verely I doe find, that this plant is named * Aſarum, becauſe it is never uſed in making of guirlands and chaplets. G

* ἀπὸ τῦ ασίρειν, i. ornare: ἀ, ςερητ, becauſe it adorneth no chaplets.

Concerning Saffron, the wild is the beſt. To plant it within any garden in Iuly, is held no good husbandrie, for it will not quit coſt, conſidering there is never a quarter ſet therewith, but it asketh a *ſcruple more in expence, than the fruit or encreaſe commeth unto, when all the cards be told. For to have Saffron grow, you muſt ſet the cloves or bulbous heads of the root: and being thus planted, it prooveth larger, bigger, and fairer than the other: howbeit ſooner far it doth degenerat and become a baſtard kind: neither is it fruitfull and beareth chives in everie place, no not about Cyrene, where the goodlieſt floures of Saffron in the world are to be ſeen at all times. The principall Saffron groweth in Cilicia, and eſpecially upon the mountaine Corycus there: next to it, is that of Lycia, and namely upon the hill Olympus: and then in a third degree of goodneſſe, is reckoned the Saffron Centuripinum in Sicilie: although ſome there bee, who attribute the ſecond place unto the Saffron of the mount * Phlegra. Nothing is ſo ſubject to ſophiſtication as Saffron: and therfore the onely triall of true Saffron indeed, is this, If a man lay his hand upon it, hee ſhall heare it to cracke as if it were brittle and readie to burſt: for that which is moiſt (a qualitie comming by ſome indirect meanes and cunning caſt) yeeldeth to the hand and makes no words. Yet is there another proofe of good Saffron, If a man after hee have handled it, reach his hand preſently up to his mouth, and perceive that the aire or breath therof ſmiteth to his face and eyes, and therewith fretteth and ſtingeth them a little; for then he may be ſure that the Saffron is right. There is a kind of garden Saffron by it ſelfe; and this commonly is thought beſt, and pleaſeth moſt, when there appeareth ſome white in the mids of the floure, and thereupon they name it Dialeucon; whereas contrariwiſe this is thought to be a fault and imperfection in the Corycian Saffron, which is chiefe: and indeed the floure of it is blacker than any other, and ſooneſt fadeth. But the beſt ſimply in any place whereſoever, is that which is thickeſt and ſeemeth to like beſt, having beſides ſhort chives like haires: the worſt is that which ſmelleth of muſtineſſe. *Mutianus* writeth, that in Lycia the practiſe is to take it up every ſeventh or eigth yeere, and remoove it to a plot of ground well digged and delved to a fine mould; where, if it be replanted, it will become freſh againe and young, whereas it was readie before to decay and degenerat. No uſe there is (in any place) of Saffron floures in garlands; for the leaves are ſmall and narrow, in manner almoſt of threads. Howbeit with wine it accordeth paſſing well, eſpecially if it be of any ſweet kind: and being reduced into powder and tempered therewith, it is commonly ſprinkled over all the theatres, and filleth the place with a perfume. It bloometh at the ſetting or occultation of the ſtar Vergiliæ, and continueth in floure but few daies: and the leafe driveth out the floure. In the mids of winter, it is in the verdure and all greene, and then would it be taken up and gathered: which done, it ought to bee dried in the ſhadow; and the colder that the ſhade is, ſo much the better. For the root of Saffron is pulpous and full of carnoſitie; and no root liveth ſo long above ground as it doth. Saffron loveth a-life to be trampled and trode upon under foot: and in truth, the more injurie is done unto it for to mar it, the better it thriveth: and therefore neare to beaten paths, and wells much frequented, it commeth forward and proſpereth moſt. H I K L

* Phlegræo: but Turnebus readeth Ægæo, according to Dioſcor.

" Ad ſcrupuli ſingula: which if you refer to a drachme, ſignifieth a third part leſſe; but if to an ounce, the 24 part.

Chap. VII.

Of the floures uſed in old time about coronets and guirlands: the great diverſitie in aromaticall and ſweet ſmelling Simples. Of Saliunca and Polium.

SAffron was (no doubt) in great credit and eſtimation, during the flouring eſtate of Troy: for certes, the Poët *Homer* highly commendeth theſe three floures, to wit, Melilote, Saffron, and Hyacinth. Of all odoriferous and ſweet ſenting ſimples, nay of all hearbs and floures whatſoever, the difference conſiſteth in the colour, the ſmell, and the juice. And note this to begin withall, that ſeldome or never you ſhall meet with any thing ſweet in ſent, but it is bitter in taſt; and contrariwiſe, ſweet things in the mouth, be few or none odoriferous to the noſe: And this is the reaſon that wine refined, ſmelleth better than new in the lees; and ſimples growing wild, have a better ſavour far than thoſe of the garden. Some floures, the farther they be off, the more pleaſant is their ſmell: come nearer unto them, their ſent is more dull and weaker than it M

was

A was, as namely Violets. A freſh and new gathered roſe caſteth a better ſmell afar off than neare at hand; let it be ſomewhat withered and drie, you ſhall ſent it better at the noſe than farther off. Generally, all floures be more odoriferous and pleaſant in the Spring, than at any other ſeaſon of the yeare; and in a morning they have a quicker and more piercing ſent, than at any houre of the day beſides: the nearer to noone, the weaker is the ſmell of any hearbe or floure. Moreover, the floures of new plants are nothing ſo ſweet as thoſe of an old ſtocke: and yet I muſt needs ſay, that floures ſmell ſtrongeſt in the mids of Summer. As for Roſes and Saffron-floures; they caſt the pleaſanter ſmell, if they be gathered in cleare weather, when it is faire & drie above head: and in one word, ſuch as grow in hot countries, bee ever ſweeter to ſmell unto, than in cold climats. Howbeit, in Ægypt the floures have no good ſent at all, by reaſon that the aire is foggie
B and miſtie, with the dewes riſing from the river Nilus. Moreover, certain floures there be which are ſweet and pleaſant enough, yet they ſtuffe and fill the head. Others, ſo long as they be freſh and green, have no ſmell at all, for the exceſſive abundance of moiſture within them; as we may perceive in Fenigreeke, which the Grecians call Buceros. Many floures caſt a quicke and lively ſmell, & yet are not without good ſtore of juice but moiſt enough, as Violets, Roſes, and Saffron: but ſuch as are deſtitute of ſuch moiſture, and yet their ſent is piercing and penetrant, they all of them be of a ſtrong ſavour alſo, as for example the Lillie of both kinds. Sothernwood and Marjeram have a hot and ſtrong ſavour. Some hearbs there be which yeeld no ſmell nor goodneſſe at all, but in their floure onely, for all their other parts be dull and good for nothing, as Violets and Roſes. Of garden hearbs, the ſtrongeſt of ſmell be alwaies drie, as Rue, Mints, and Ach or
C Parſley: likewiſe are all ſuch as grow in drie places. Some fruits, the elder they bee and the longer kept, the ſweeter is their ſavor, as Quinces: and the ſame Quinces *de gard* ſmell better when they be gathered, than if they hung ſtill upon the tree, and ſo preſerved. Others there are, that unleſſe they be broken, bruiſed, rubbed, and cruſhed, have no ſmell: and ye ſhall have thoſe that caſt no ſent at all, unleſſe their rind or barke be taken off: as alſo ſuch, as except they be caſt into the fire and burnt, yeeld no ſavour, as Frankincenſe and Myrrhe. Furthermore, all floures being bruiſed, are more bitter than they were untouched and unhandled. Some, after they be drie, reteine their odour longeſt, as the Melilot. There are that make the place more ſweet where they grow, as the flour-de-lis; inſomuch as it perfumeth the whole tree (whatſoever it is) the roots wher-of it toucheth. The hearbe Heſperis ſmelleth more by night than day, wherupon that name was
D deviſed. * There are no living creatures which yeeld from their bodies a ſweet ſavour, unleſſe we give credit to that which hath been reported of the Panthers.

Furthermore, this would not be paſſed over, as touching the difference of odoriferous plants and their flours in this reſpect; that many of them are never emploied to the making of guirlands and chaplets, as namely the Floure-de-lis, and Nard Celticke, Saliunca, which notwithſtanding they yeeld both of them an excellent ſavour, yet are not uſed that way. But as for the * Floure-de-lis, it is the root onely thereof that is comfortable for the odour; as if Nature had made the plant it ſelfe to ſerve only for Phyſick uſes, and compoſitions of ſweet perfumes. The beſt Floure-de-lis is that which groweth in Illyricum or Sclavonia; and not in all parts thereof, not (I ſay) in
E the maritime coaſts, but farther up into the maine, among the mountains and forreſts of Drilo and Narona. The next to it in goodneſſe, commeth out of Macedonie, and it hath the longeſt root of all others, but ſlender withall and whitiſh. In the third place is to be raunged the Floure-de-lis of Africke or Barbarie; which, as it is the biggeſt in hand, ſo is it the bittereſt alſo in taſt. As touching the Illyrian Ireos, there be two ſorts of it; namely, Rhaphanitis, which is the better of the twain, ſo called for the reſemblance that it hath to the Radiſh root: the ſecond they name Rhizotomos, and it is ſomewhat reddiſh. In ſumme, the beſt Ireos, if a man doe but touch it, will provoke ſneeſing. The ſtem of the Floure-de-lis groweth ſtreight and upright, to the heigth of a cubit. The floure is of divers colours, like as we ſee in the rainbow, whereupon it tooke the name Iris. The Ireos of Piſidia is not rejected, but held to be very good. Moreover, they uſe in Sclavo-
F nia to be very ceremonious in digging up the root of Flour-de-lis: for three months before they purpoſe to take it foorth of the ground, the manner is to poure mead or honeyed water round about the root in the place where it groweth, having beforehand drawne a threefold circle with a ſwords point; as it were to currie favour with the Earth, and make ſome ſatisfaction for breaking it up and robbing her of ſo noble a plant: and no ſooner is it forth of the ground, but preſently they hold it up aloft toward heaven. This root is of a fervent and cauſticke nature, for in the very

* *Plinie* never heard of the Musk-goats nor Civet-cats in theſe daies.

* Commonly called *Ireos*.

handling it raiſeth pimples and bliſters in manner of a burne, upon their hands who gather it. G
Another ceremonie alſo they have in the gathering thereof, for none muſt come about this worke, but ſuch as have lived chaſt, and not touched a woman: this (I ſay) above all, is obſerved moſt preciſely. This root of all others is moſt ſubject to the worme, for not onely when it is drie, but alſo whiles it is within the earth, it quickly commeth to be worme-eaten. In old time, the beſt Irinum, or oile of Ireos, was brought from the cape of Leucas, and the cittie of Elis in Bœotia; for planted it hath been in thoſe parts many a yeare. But now there is excellent good commeth out of Pamphylia: howbeit that of Cilicia, and namely from the Septentrionall parts, is moſt highly commended.

As for the plant Saliunca, or Nard-Celticke, full of leaves verely it is, yet they bee ſo ſhort, that handſomly they cannot be knit & twiſted for guirlands: a number of roots it putteth forth, H
unto which the floure or hearbe groweth cloſe: for ſurely a man would judge it all hearbe rather than floure, as if it were platted and preſſed flat to the root with ones hand: and in a word, reſembling a very thick tuft of graſſe by it ſelfe. This hearbe groweth in Auſtria and Hungarie; alſo among the Morici, and the Alps on the Sun ſide. As for that which commeth up about the cittie Eporrhedia, it is ſo pleaſant and odoriferous, that there is as much ſeeking after it as if it were ſome precious mettall; and it yeeldeth a revenew to the cittie, no leſſe than ſome mettall mine. And in very truth, a ſingular hearbe it is in a wardrobe to lye among good cloaths, for to get them a moſt pleaſant and commendable ſmell.

Another plant there is which the Greeks uſe likewiſe in their wardrobes, called Polium. This hearbe *Muſæus* and *Heſiodus* the Poets, extoll and ſet out to the higheſt degree; for they report I
that it is good for all things that it ſhall be emploied about; but principally, that it availeth much to win men fame, renowme, promotions, and dignities. Over and above which vertues, miraculous it is (if it be true which they ſay) * that the leaves thereof in the morning ſeeme white, about noone purple, and at the Sun-ſetting blew. Two kinds there be of it: one groweth in the plains and champion grounds, and is the greater: another in the woods, and is the leſſe. Some call it Teuthrion. The leaves reſemble the gray hairs of an old man, ſpringing directly from the root, and never paſſe in heigth a hand bredth. Thus much may ſuffice concerning odoriferous flours.

* *Dioſc.* reporteth this of *Tripolium*, and not of *Polium*: wherby it ſeemeth that *Plinie* is in a fault.

Chap. viii.

The colours of cloth reſembling thoſe of floures, and ſtriving with them for the better. Of Amarantus or Paſſe-velours: of Chryſocon or Chryſitis. K

THe exceſſive ryot and prodigall ſuperfluitie of men is growne to this paſſe, that having taken no ſmall pleaſure in ſurmounting the naturall ſavour of ſimple floures, by their artificiall odours and compound perfumes; they cannot reſt ſo, but muſt proceed alſo in the craft and myſterie of dying cloth, to challenge the faireſt floures in the garden, and to match, if not to ſurpaſſe, the lively colours of Natures ſetting. Of theſe tinctures, I find that there be three principall: The one in graine, which ſtriveth with that bright orient colour in Roſes: and there is not a more pleaſant thing to the eye, than to ſee the Scarlet or purple of Tyros, or to behold the double died Dibapha, or the Laconian purple. The ſecond rich die, ſtandeth upon the Ame- L
thyſt colour, and reſembleth the March violet: this alſo beareth much upon that purple, which of the ſaid violet is called Ianthinus: for now I handle dies and colours in generall tearms, which nevertheleſſe may be ſubdivided into many other ſpeciall ſorts. The third, is ordinarily made of the purple and porcellane ſhell-fiſhes, and that in divers and ſundrie maners; for of this tincture there are cloaths which encline much to the colour of Tornſoll; and of theſe, ſome bee many times of a deeper and fuller die than others. Alſo there is another ſort that ſtandeth much upon the Mallow floure, enclining to a purple: and a third ſort which reſemble the violet that commeth late in the yeere [called the purple Stocke-gillofre] and indeed this is the freſheſt and richeſt colour that can be died out of thoſe fiſhes aforeſaid. Certes, the tinctures and dies now adaies are ſo lively, as well for ſimple colours as mixt and compound (ſuch artificiall means are deviſed by M
our ſumptuous gallants) that in this ſtrife of Nature and Art togither, a man ſhall hardly judge whether of them have the better hand. As touching Yellow, I find that it is a moſt auncient colour, and highly reputed of in old time: for the wedding vaile which the bride ware on her marrying day, was all of Yellow, and women onely were permitted to uſe them: which might well be

the

A the cauſe that this colour is not reckned among thoſe that be principall, that is to ſay, common as well to men as women: for the wearing and uſing of colours indifferently by the one and the other, is that which hath given them their name and ſpeciall credit. Howbeit, doe what we can, for all our skill and induſtrie wee muſt give place without all doubt to the purple floure-gentle, for we cannot reach poſſibly to the colour thereof. Now to ſay a truth, a purple Spike rather this is than a floure, and the ſame altogither without any ſmell. Of a ſtraunge and wonderfull nature this is: it loves of all things to be cropped, and the more it is plucked, the better it commeth againe: it beginneth to ſpike or put out the floure in the month of Auguſt, and continueth untill Autumne. The beſt is that of Alexandria, for after it is gathered, it will keepe the freſh and lively colour ſtill. This marveilous propertie it hath by it ſelfe, That when all other floures doe faile
B and are gone, if it be wet in water it looketh freſh againe; and for want of others, ſerves all winter long to make chaplets & guirlands. The chiefe and principall vertue that it hath, is ſhewed in the very name Amaranthus, for ſo it is called in Greeke, becauſe it never doth fade or wither.

But to come againe to our artificiall colours, we have one that anſwereth to the floure named Cyanos, *i.* Blewbottle: likewiſe to the yellow golden floure Elichryſon. Verely none of all theſe flours or colours were in requeſt in the daies of K. *Alexander* the Great; for the Greeke authors who wrote next after his deceaſe, have made no mention at all of them: whereby it is plain, that they grew into a name and liking ſince their time. Howbeit no man needs to make doubt or queſtion, That found out they were firſt by the Greekes: for how els ſhould it bee, that their names which be meere Greekiſh, are currant here in Italie? Howbeit this cannot be denied, that Italie
C hath given name to the hearbe Petilium, which floureth in Autumne, groweth about briers and brambles, and is onely commendable for the colour ſake, which is much like to the wild Roſe or Eglantine: the leaves of which floure be ſmall, and no more than five. A wonderfull thing to be noted in this floure, That the head ſhould bend and nod downward ſo, as unleſſe it bee thus (as it were) wreathed and bowed, the ſaid leaves will not ſhew out of a ſmall cup or veſſell of ſundrie colours, and encloſing within it a yellow ſeed.

As touching a Daiſie, a yellow cup it hath alſo, and the ſame is crowned as it were with a garland conſiſting of five and fiftie little leaves, ſet round about in manner of fine pales. Theſe be floures of the medow, and moſt of ſuch are of no uſe at all; no marvrile therfore if they be nameleſſe: howbeit ſome give them one tearme, and ſome another. As for Chryſocon or Chryſitis,
D no Latine denomination it hath at all: an hearbe it is, growing an hand-breadth high, putting forth certaine buttons (as it were) in the head, glittering as bright as gold, with a blacke root, taſting harſh and yet ſweetiſh withall: it groweth commonly in places full of ſtones and ſhadowie.

Chap. IX.

The excellencie of Chaplets and Guirlands: of Cyclaminus, and Melilot: of Trifolie or Claver, and three kinds thereof.

NOw that we have gone through in manner the principall dies and richeſt colours that be,
E it remaineth that we paſſe to the treatiſe of thoſe guirlands, which beeing made of divers coloured flours, in regard only of that varietie, are delectable and pleaſing to the eye. And conſidering that ſome of them ſtand upon flours, others of leafe, they may be all reduced to two principall heads. Among flours, I take to be all kinds of broome (for from them there be gathered yellow floures) and the Oleander. *Item*, the bloſſoms of the Injube tree, which alſo is called Cappadocia, for they reſemble much the odor of the Olive bloums. As for Cyclaminum, *i.* Sowbreed, it groweth among buſhes; whereof more ſhall be ſaid in another place: a purple Coloſſian floure it carieth, which is uſed to beautifie & ſet out game-coronets. To come now to chaplets made of leaves; the faireſt that goe unto them, be *Smilax and Ivie; and therein alſo their *Bindweed.
berries interlaced among, do make a goodly ſhew above all: of which we have ſpoken at large in the treatiſe of ſhrubs and trees. Many kinds there are beſides of plants proper for this purpoſe,
F which we muſt be faine to expreſſe by Greeke names, foraſmuch as our countreymen have not been ſtudious in this behalfe, to give any Latine names to the greateſt part of them: beſides, moſt of them are meere ſtraungers in Italy, and grow in forrein parts: howbeit, looked for it will be at our hands that we ſhould enter into the diſcourſe of them alſo, for that our purpoſe and deſign reacheth to all the works of Nature, and is not limited & confined within the bounds of Italy.

* *Vitis alba*, of some: *Glycypicron Dodonæi*, of others.
* *Viburnum Matthioli.*

Well then, to begin withall, * Melothron, Spireon, Trigonon, * Cneoron (which *Hyginus* calleth Casia) affourd leaves very meet to make chaplets: so doth Conyza, called otherwise Cunilago; Melyssophyllon, named also Apiastrum, *i.* Bawme; and Melilot, which we commonly terme Sertula Campana; and good reason, for the best in Italy is that of Campaine: and in Greece, that which groweth in the promontorie Sunium. Next to these, the Melilot of Chalcis & Candie is well accepted of: but grow it in what countrey it will, rough thickets and woods it delighteth most in. And that of this hearbe they were woont usually in old time to make garlands, may appeare by the very name Sertula, which it tooke thereupon, and retaineth still. In savor & floure both, it commeth neare to Saffron: the hearbe otherwise of it selfe is hoarie and gray. The best Melilot is that counted which hath shortest leaves, and those most plumpe and fattie withall. Semblably, the hearb Trifolie or Claver, hath leaves which goe to the making of coronets and guirlands. And hereof there be three kinds: the first is that which the Greeks call Mynianthes, others Asphaltion, having a bigger leafe than the rest; an hearb that garland-makers commonly use: the second with a sharpe leafe, called thereupon Oxytriphyllon: the third, which is least of all other. Among these Trefoiles, I cannot but advertise the reader, that some there be which have strong and firme stems, as nervous as those of garden Fennell and Fennell wild, yea and as stiffe as those of Myophonos. But to returne againe to our chaplets, there bee emploied about them, both the maine stalks of Ferula, as also the berries and purple floures of the Ivie. There is besides a kind of them, like unto the wild roses: and in them verely the colour only is delectable, for odour they have just none. To conclude, of Cneoron there be two kinds, the blacke and the white: both well branched and full of leaves, but the white is most odoriferous: and as well the one as the other, doe flourish after the Æquinox in Autumne.

Chap. X.

Of Oryganum, and Thyme: of the Athenien honey: of Conyza, and Iupiters floure: of Sotherwood and Camomile.

As many sorts also there be of Origanum, serving to make guirlands: as for one of them, it hath no seed; but the other which is sweet, is called Origan of Candie. In like manner, two kinds there be of Thyme, to wit, the white and the blacke: this hearbe doth flourish about the Summer Solstice, at what time as Bees also begin to gather honey from it; and according to the flouring of it more or lesse, a man may guesse full well what season there will be for honey: for honey-mistresses and such as keepe Bees, hope to have a good yeere of honey, when they see the Thyme to bloume abundantly. Thyme cannot well away with raine, and therefore it taketh harme by showres and sheddeth the floure. Thyme seed lyeth so close, that unneth or hardly it can be found; whereas the seed of Origan, notwithstanding it bee exceeding small, is evident enough and may soone be seene. But what matter makes it, that Nature hath so hidden the seed, considering it is well knowne, that it lyeth in the very floure, which if it be sowne, commeth up as well as any other seed? See the industrie of men, and how there is nothing but they have made triall of and put in practise! The honey of Athens carrieth the name for the best honey in the world, by reason of the Thyme growing thereabout. Men therfore have brought over into other countries, Thyme out of Attica, although hardly and with much adoe (being sowne thus in the floure as I have said) it commeth up. But there is another reason in Nature, why it should thrive so badly in Italy or elsewhere, considering that the Attick Thyme will not continue and live, but within the aire and breath of the Sea. Certes this was an opinion received generally of our auncient fore-fathers, That no Thyme would doe well and prosper, but neare unto the Sea; which should be the cause, that in Arcadia there is none of it to be found. And in those daies also, men were verely persuaded, that the Olive would not grow but within the compasse of three hundred stadia from the Sea side. Howbeit, in this our age verely, we are advertised and know for certain, That in Languedoc and the province of Narbon, the very stonie places are all overgrowne and covered with Thyme, upon which there are fed thousands of sheepe and other cattaile: in such sort, as this kind of herbage and pasturage, yeeldeth a great revenue to the inhabitants and paisants of that countrey, by joisting and laying in of the said beasts, brought thither out of far remote parts for to feed upon Thyme.

Concerning the hearbe Conyza, which goeth also to the making of Chaplets, there bee two kinds

A kinds likewiſe of it, namely, the male & the female. And theſe differ onely in the leaves. For thoſe of the female Conyza be thinner, ſmaller, narrower, and growing cloſer together than the other of the male, which indeed braunch and ſpread abroad more, lapping one over another in manner of creſt tiles. The flowers alſo of the male Conyza is more bright and lively: howbeit, both the one and the other flower late, and not before the riſing or apparition of the ſtarre Arcturus. The male carieth a ſtrong ſent: but that of the female is more penetrant; in which regard the female is better for the bite and ſting of venomous beaſts. The leaves of the female, ſmell of Honey. The root of the male, is by ſome called Libanotis, whereof we have alreadie written.

As touching theſe hearbes following, *Dios Anthos, Majoran, the day Lillie, Hemerocalles, Sothernwood, Elecampane, water Mints, and wild running Thyme, as alſo all which doe branch
B and put forth ſhoots as Roſes doe, ſuch ſerve onely in leafe for Guirlands. As for the ſaid *Iupiters* flower or Dios Anthos, particularly, there is nothing in it but the colour to commend it; for ſavour it hath none, no more than another hearbe which the Greekes call Phlox. As for the reſt, their flowers and braunches both be odoriferous, except the running wild Thyme.

Elecampane, named in Greeke Helenium, ſprang firſt (as men ſay) from the teares of ladie *Helena*: and therefore the beſt Elecampane is that which groweth in the Iſland of Helena. The plant is leafed like unto wild Thyme, ſpreading and running low by the ground with little braunches, nine inches or a ſpan long.

Sothernwood doth flouriſh in Summer, and carieth a ſweet and pleaſant ſavour, howbeit, the head it ſomewhat ſtuffeth and offendeth. The flower is of a golden colour. And ſay, that it carieth
C neither ſeed nor flower, yet commeth it up of it ſelfe in void and vacant places altogether neglected and without any culture, for it doth propagat and encreaſe by the tops and tips of the branches lying upon the ground, and ſo taking root. And therefore it groweth the better if it be ſet of root or ſlip, than ſowed of ſeed. For of ſeed, much adoe there is to make it come up. And when it is above ground, the young plants are removed and ſet, as it were in *Adonis* gardens, within pots of earth; and that in Summer time, after the manner of the hearbe and flower Adonium. For as well the one as the other be very tender, and can abide no cold: and yet as chill as they bee, they may not away with over-much heat of the Sunne, for taking harme. But when they have gotten head once and be ſtrong ynough, they grow and branch as *Rue doth.

Much like unto Sothernwood in ſent and ſmell, is Camomile: the flower is white, conſiſting
D of a number of pretie fine leaves ſet round about the yellow within.

* or *Iovis Flos*, which ſome take to be the Columbines.

*Helenium here deſcribed agreeth not with our Elecampane.

*Rutæ vide.

Chap. xi.

Of Marjoram, the greater and the leſſe, called in Latine Amaracus or Sampſuchum. Of Nyctygretum, Melilote, the white Violet: of Codiaminum, and wild Bulbes: of Heliochryſum, and Lychnis or Roſe Campian. And of many other hearbs growing on this ſide the ſea.

E *Diocles* the Phyſician, and the whole nation in manner of the Sicilians, have called that hearbe Amaracus, which in Ægypt and Syria is commonly named Sampſuchum. It commeth up both waies, as well of ſeed as of a ſlip and braunch. It liveth and continueth longer than the hearbes beforenamed, and hath a more pleaſant and odoriferous ſent. Marjoram is as plentifull in ſeed, as Sothernwood: but whereas Sothernwood hath but one tap-root and the ſame running deep into the ground, the reſt have their roots creeping lightly aloft and eb within the earth. As for all the other hearbes, they are for the moſt part ſet and ſowne in the beginning of the Autumne: ſome of them alſo in the Spring, & namely in places which ſtand much in the ſhade, which love to be well watered alſo and enriched with dung.

As touching Nyctygretum [or Lunaria] *Democritus* held it to be a wonderfull hearb, and few like unto it; ſaying that it reſembleth the colour of fire, that the leaves be prickie like a thorn, that it creepeth along the ground: he reporteth moreover, That the beſt kind thereof groweth in the
F land Gedroſia, That if it bee plucked out of the ground root and all after the Spring Æquinox, and be laid to drie in the Moonſhine for three daies together, it will give light and ſhine all night long; alſo, That the Magi or Sages of Perſia, as alſo the Parthian kings uſe this hearbe ordinarily in their ſolemne vowes that they make to the gods: laſt of all, That ſome call it Chenomychos, becauſe Geeſe are afraid of it when they ſee it firſt; others name it Nyctilops, becauſe in the night

night ſeaſon it ſhineth and glittereth a farre off. As for Melilote, it commeth up every where : howbeit, the beſt ſimply, and wherof is made the greateſt account, is in Attica. But in what place ſoever it groweth, that is moſt accepted which is freſh and new gathered, not enclining to white, but as like unto Saffron as is poſſible. And yet in Italie the white Melilote is the ſweeter and more odoriferous. G

The firſt flower bringing tidings of the Springs approch, is the white bulbous ſtock-Gilloſre. And in ſome warmer climats they put forth & ſhew even in Winter. Next unto it for their timely appearance, is the purple March Violet: and then after them the Panſe, called in Latine Flammea, and in Greeke Phlox, I meane the wild kind onely.

Codiaminon bloweth twice in the yeare, namely, in the Spring and the Autumne: for it cannot abide either Winter or Summer. Somewhat later than thoſe before rehearſed, are the Daffodill and Lillie ere they flower, eſpecially in countries beyond ſea. [In Italie verely (as I have ſaid before) they bloum not untill after Roſes:] for in Greece the Paſſe-flower *Anemone is yet more lateward. Now is this Anemone the flower of certaine wild Bulbes, different from that other Anemone, whereof I will ſpeake in the Treatiſe of Phyſicke-hearbes. Then followeth *Oenanthe, and Melanion, and of the wild ſort Heliochryſos. After them, a ſecond kind of Paſſe-flower or Anemone, called alſo Leimonia, beginneth to blow. And immediately upon it the petie Gladen or ſword-graſſe, accompanied with the Hyacinth. And laſt of all, the Roſe ſheweth in her likenes. But quickly hath the Roſe done, and none ſo ſoone, and yet I muſt except the garden Roſe. Of all the reſt, the Hyacinths or Harebels, the *ſtocke Gillo flower, and Oenanthe or Filipendula, beare flowers longeſt. But of this Oenanthe, this regard muſt be had, that the flowers bee often picked and plucked off, and not ſuffered to run to ſeed. This groweth in warme places. It hath the very ſame ſent that Grapes when they firſt bud and put out bloſſome, whereupon it tooke the name Oenanthe. But before I leave the Hyacinth, I cannot chuſe but report the fable or tale that goeth thereof, and which is told two manner of waies, by reaſon that the flower hath certain veines to be ſeene running in and out, reſembling theſe two letters in Greeke A I, plaine and eaſie to be read: which as ſome ſay, betoken the lamentable mone [αι] that *Apollo* made for his beloved wanton minion *Hyacinthus*, whom he loved: or as others make report, ſprung up of the bloud of *Ajax* who ſlew himſelfe, and repreſented the two firſt letters of his name AI. H I

*Pulſatylla or Wind-flower.

*Filipendula ſuppoſed of ſome.

*or rather the Wall-flower.

Heliochryſos beareth a yellow flower like to gold, a ſmall and fine leafe, a little ſtalke alſo and a ſlender, but hard and ſtiffe withall. The Magi or Sages of Perſia uſe to weare this hearb and flour in their Guirlands: and they be fully perſuaded, that by this meanes they ſhall win grace and favour in this life, yea, and attain to much honor in glorie; provided alwaies, that their ſweet compoſitions wherewith they annoint and perfume themſelves, be kept in a veſſell or box of gold not yet fined nor purified in the fire; which gold they call Apyron. And thus much for the flowers of the Spring. K

Now ſucceed and come after in their ranke, the Summer flowers, to wit, Lychnis, *Iupiters* flower or Columbine, and a ſecond kind of *Lillie: likewiſe Iphyon, and that Amaracus or Marjeram, which they call the Phrygian. But of all others, the flower Pathos is moſt lovely and beautifull: whereof there be two kinds, the one with a purple flower like unto the Hyacinth; the other is whiter, and groweth commonly in churchyards among graves and tombes, and the ſame holdeth on flouring better, and liveth longer. The flower de Luce alſo is a Summer flower. Theſe have their time, fade, and are ſoone gone. And then come other flowers for them in their place in Autumne, to wit, a third kind of Lillie, and Saffron: But of both theſe, the one is of a dull or no ſent at all: the other is very odoriferous. But all of them breake out and ſhew abroad with the firſt ſhower of raine in Autumne. Our Chaplet-makers uſe the flowers alſo of Bedegnar or white Thiſtle in their Guirlands: and no marvell, ſince that our Cookes dreſſe the young tendrels and crops thereof, for to make a daintie diſh for to content our raſt and goe pleaſantly downe the throat. Thus you ſee the order and manner of beyond-ſea flowers, how and when they come abroad. In Italie it is ſomewhat otherwiſe: for the Roſe followeth immediately after the Violets: and when the Roſe is in the mids of his ruffe, in comes the Lillie to beare him companie. No ſooner hath the Roſe plaied his part, but the blew-Blaw entereth the ſtage: and after him the Paſſeveleur or Flower-gentle. As for the Pervincle, it continueth freſh and greene all the yeare long: this hearbe windeth and runneth too and fro with her fine and ſlender twigges in manner of threds or laces, and thoſe beſet with leaves two by two in order, at every knot or joint. L M

*Some read Cerinthus rather.

Paſſing

A Paſſing good and proper indeed for vinet and ſtorie worke in borders, arbours or knots,& meet for fine and curious Gardeners: howbeit, for default of other flowers,the Garland-makers borrow a little of the law,and make up their defects with a ſupplie from it. The Greekes call it Chamædaphne.

The life of the white Violet or bulbous ſtocke-Gillofre,is three yeares at moſt, and ſo long it holdeth the owne well; after that tearme it doth degenerat and wax worſer. The Roſe-buſh will continue five yeares, without cutting downe or burning (which are the meanes to maintaine it in youth ſtill.) But as we have alreadie obſerved,there lieth very much in the ſoile,which would be conſidered eſpecially in flowers: for in Ægypt, none of all theſe above rehearſed,have any odour or ſent at all; and yet the Myrtle trees there, they alone carie a moſt ſweet and pleaſant ſa-
B vour. Moreover,in ſome tracts all theſe hearbes and flowers beforenamed, doe prevent in budding and blowing (two months) thoſe of other places. As for Roſe-rewes,the earth ought to bee digged & opened about the roots; firſt preſently upon the comming of the Weſterne wind Favonius in Februarie, and then a ſecond time about the Summer Solſtice: to conclude, theſe would be looked unto above all things,that before and betweene thoſe times, they bee kept well pruned and cleanſed from all ſuperfluities.

Chap. xii.

The order of nouriſhing and maintaining Bees. What meat is to be given them.
C *Their diſeaſes,and the remedies to them belonging.*

IN this diſcourſe of ours concerning Gardens and gay flowers appertaining to Guirlands, requiſit it is to ſpeake of Bees and Bee-hives, which become the garden very well: conſidering the gaine that commeth in ſo eaſily by them,eſpecially when they ſtand and do well.In regard therefore of theſe Bees,ſo beneficiall as they bee,and kept with ſo ſmall charges,a garden ought to be well planted and ſtored with Thyme,Baulme,Roſes,Violets of all kinds,Lillies,ſweet Trefoile,Beanes,Ervile,Cunila or Saverie,Poppies,Conyza, Caſia, to wit,Lavander and Roſemarie,Melilote, Meliſſophyllum, and Cerinthe. This Cerinthe is an hearbe bearing white leaves, and thoſe bending downeward: it groweth a cubit high,and carrieth an hollow head,containing
D within it a certaine ſweet liquour reſembling honey: Bees are moſt eager and greedie after the flower of this hearbe,as alſo of Senvie; whereat we may well make a wonder, ſeeing that for certaine they will not touch nor come neare to the bloſſome of the Olive trees.And therefore good it is to ſet Bee-hives farre ynough from this tree. And yet of neceſſitie ſome there would be planted neare unto them,that when the Bees do ſwarme or caſt, they might have a convenient place at hand to ſettle upon,for feare they ſhould flie too farre from the hive. The Cornell tree alſo is not good for Bees, for if they chaunce to taſt the flower thereof, they fall preſently into a vehement laske,whereof the poore wretches (if they have not helpe the ſooner) die: and therefore it would not ſtand in their way. Howbeit, there is a remedie to cure them of this Flux, namely, to take ſorviſes and ſtampe them together with honey, and ſo to give it them: to ſet unto them ei-
E ther mans urine or beaſts ſtale: or elſe laſt of all to ſerve them with graines of the Pomgranate, beſprinckled and drenched in wine of the Amminean grape. But if you ſet Browme all about their hives, you doe them an high pleaſure.

As touching their food and nouriſhment, I will tell you a wonderfull and memorable thing upon mine owne knowledge.There is a towne or Burgade called Hoſtilia, ſituate upon the river Po, the inhabitants of this village, when they ſee that their Bees meat goeth low therabout,and is like to faile,take me their hives with Bees and all,and ſet them in certaine boats or barges,and in the night row up the ſaid river Po againſt the ſtreame five myles forward. The morrow morning out goe the Bees to ſeeke food and releefe. Now when they have met with meat, and fed themſelves, they returne againe to the veſſels aforeſaid: and thus they continue daily,although
F they chaunge their place and haunt; untill ſuch time as their maiſters perceive that the hives be full,by the ſettling of their boats low within the water with their weight,and then they return home againe downe the ſtreame,and diſcharge the hives of the honey within.

Chap.

G

Chap. xiii.

Of a certaine venomous and poysonfull Honey. The remedies as well against the said Honey, as another kind that maketh folke besides themselves.

SEmblably in Spaine they deale with their Bees and hives upon Mules backs in the like case, and carie them up into the countrey for to bee provided of victuals. But here it would bee considered by the way, what pasturage it is that they be put into; for that there is some kind of food, which poysoneth all the honey that is gathered from it. At Heraclea in Pontus, in some yeares, all the honey that the Bees do make, is found to be venomous and no better than poyson; and yet the same Bees in other yeares gather good and holesome honie. Howbeit, those authors H
who have delivered thus much in writing, have not set downe what flowers they bee that yeeld this hurtfull honey: and therefore I thinke it not amisse to write what I have found and known as touching this point. There is an hearbe called Ægolethron in Greeke, which killeth horses verely, but Goats most of all, feeding thereupon; and therfore it tooke that name: the flowers of this hearbe, if it chaunce to be a wet and rainie Spring, do conceive and engender within them a certaine deadly venome which doth corrupt and rot them. This may be a propable reason, that the foresaid mischeefe and bane is not alwaies felt alike. This poysonsome honey may be knowne by these signs: First it will never thicken but continue liquid still; secondly, the colour is more deep and reddish than ordinarie; thirdly, it carrieth a straunge sent or smell with it, and will cause one to sneese presently; last of all, it is more ponderous and heavie than the good and harmelesse I
hony. The symptomes or accidents that ensue upon the eating of this honey, are these, They that have tasted thereof, cast themselves upon the ground and there fall a tumbling: they seeke by all meanes they can to be cooled: and no marvell, for they run all to sweat, that one drop overtakes the other. Howbeit, there bee many remedies for this poyson, which I will shew in place convenient. Meane while, because a man would not be without some good thing readie at hand, since the world is so full of villanie and set upon such secret mischeefe, I must needs put down one good receit, and that is this: Take honied wine that is old, mingle and incorporat it with the best honey you can meet withall, and Rue together: use this confection at your need. *Item*, Eat much of salt-fish, although it come up againe, and that your stomacke doe cast it. Moreover, this honey is so pernicious, that the very dogges if they chaunce to licke up any excrements that passe from the K
partie so infected (either by reaching, spitting, vomit, or seege) they are sure to be sped therewith, and to feele the like torments. Howbeit, the honied wine that is made therewith, if it may have age ynough and be stale, is knowne for a certainetie to doe no creature harme. And there is not a better medicine in the world, either to fetch out spots in womens faces, and make their skinne faire and cleare (if it be applied with Costus;) or to take out the blacke and blew marks remaining after stripes in eye or elsewhere, so it be tempered with Aloe. Another kind of honey there is in the same region of Pontus, and namely among the Sanni (a people there inhabiting) which because it driveth folke into a fit of rage and madnesse, they call in Greeke Mænomenon. Some attribute the occasion hereof to the flower of the Oleander, whereof the woods and forrests there be full. This nation selleth no hony at all, because it is so venomous and deadly: notwithstanding L
they doe pay for tribute a huge masse of wax unto the Romanes every yeare. Moreover, in the kingdome of Persis, and in Getulia, which lieth within Mauritania Cæsarienſis, a countrey confining and bordering upon the Massæsuli, there be venomous honey-combs; yea, you shall have in one hive some honey-combes full of poysoned honey, whereas others be sound and good: a daungerous thing no doubt, and than which, there could bee no greater deceit to poyson a number of people; but that they may be knowne from the rest by their leaden and wan hew that they have. What should we think was Natures meaning and intent by these secret slights and hidden mischeefes, That either the same Bees should not every year gather venomous honey; or not lay the same up in all their combes differently? Was it not ynough that she had bestowed upon us a
thing, wherein poyson might be soonest given and least perceived? Was shee not content thus M
to endaunger our lives, but shee must proceed farther, even to incorporat poyson her selfe in honey, as it commeth from the Bee, for to empoyson so many living creatures? Certes, I am of this mind and beleefe verely, That she had no other purpose herein, than to make men more warie what they eat, and lesse greedie of sweet meats to content and please the tooth. For the very

honey

A honey indeed ſhe had not generally infected with this hurtfull qualitie, like as ſhe had armed all Bees with ſharpe prickes and ſtings, yea, and the ſame of a venomous nature: & therfore againſt theſe creatures verely ſhe hath not deferred and put off to furniſh us with a preſent remedie. For the juice of Mallowes or of Yvie leaves ſerveth to annoint the ſtinged place, and keepe it from rankling: yea and it is an excellent thing for them that be ſtung, to take the very Bees in drinke; for it is an approoved cure. But this I marvell much at, That the Bees themſelves, which feed of theſe venomous hearbs, that carie the poyſon in their mouths, and are the makers of this miſcheevous honey, doe eſcape & die not thereof? Whereof I can give no reaſon at all, unleſſe dame Nature, that ladie and miſtreſſe of the world, hath given unto theſe poore Bees a certaine Antipathie and vertue contrarie unto poyſon: like as among us men to the *Marſi* and *Pſylli*, ſhe hath
B imprinted (as it were) a repugnancie in their bodies, to reſiſt the venome of all Serpents whatſoever.

Chap. xiiii.

Of a certaine kind of honey which Flies will not touch. Of Bee-hives. How to order the ſame, and namely when Bees want meat and are in daunger to be famiſhed. The manner alſo of making Wax.

THere is in Candie another ſtraunge and woonderfull thing, as touching Honey, gathered about the mountaine Carina, which taketh nine miles in compaſſe: within which ſpace and circuit of ground, there is not a Flie to be had; and the honey there made, Flies wil not
C touch in any place whereſoever. By which experiment, this honey is thought to bee ſingular for medicines, and therefore choiſe is made thereof before any other.

As touching Bee-hives, they ought to ſtand on the open ſide upon the Æquinoctiall Sunne riſing, that is to ſay, when the daies and nights be equall. And in any wiſe, regard would bee had, that they open not into the Northeaſt, and much leſſe the full Weſt. The beſt Bee-hives be made of barkes and rinds of trees: the ſecond in goodneſſe be thoſe of Ferula or Fennell-geant. In the third place are ſuch as be wrought of oiſier twigs. Many have made them of Talc, which is a kind of tranſparent glaſſe ſtone, becauſe they would ſee through them how the Bees doe worke and labour within. Daubed they ſhould be if they were well ſerved, both without and within with Oxe dung. The cover and lid thereof ought to be mooveable and have libertie to play up and downe
D behind, that it may bee let downe farre within-forth, in caſe either the hive bee too large and of greater receit in proportion than the Bees are in number; for feare they ſhould ſlacke their work and give over their travell, deſpairing ever to fill the ſame, ſeeing it ſo big and of ſo great capacitie: and being thus let downe (to make the hive ſeeme the leſſe) it muſt be gently drawn up again by little and little, that the Bees may be deceived thereby, and not perceive how their work grows upon them. In Winter time Bee-hives ſhould be covered with ſtraw: and oftentimes perfumed with beaſts dung eſpecially; * for this is agreeable to their nature. Over and beſides, it killeth the wicked vermine that breed in them, Spiders, Butterflies, and Wood-wormes: yea, and this propertie it hath moreover, to ſtirre up and quicken the Bees, and make them more lively and nimble about their buſineſſe. As for the Spiders aforeſaid, they verely are not ſo harmefull, and bee
E ſoone deſtroied: but the Butterflies doe the more miſcheefe, and are not ſo eaſily rid away. Howbeit, there is a way to chaſe them alſo, namely, to wait the time when the Mallow dooth begin to bloſſome, to take the chaunge of the Moone, and chuſe a faire and cleare night, and then to ſet up certaine burning lights juſt before the Bee-hives: for theſe Butterflies will covet to flie into the flame. But what is to be done, when you perceive that the Bees doe want victuals? Then it will be good to take drie Raiſins of the Sunne, and Figges, to ſtamp them together into a maſſe, and lay it at the entrie of the hive. *Item*, It were not amiſſe to have certaine lockes of wooll well touzed & carded, and thoſe wet & drenched in cuit either ſodden to the thirds, or to two thirds, or els ſoked in honied wine, for them to ſettle upon and ſucke. Alſo to ſet before them in their way the raw carkaſes of Hens, naked and pulled to the bare fleſh. Moreover, there be certaine Summers
F ſo drie and continually without raine, that the fields want flowers to yeeld them food, and then muſt they bee ſerved with the foreſaid viands, as well as in Winter ſeaſon. When honey is to be taken forth of the hives, the holes and paſſages for the ingreſſe and egreſſe of the Bees ought to be well rubbed and beſmeared with the hearbe Meliſſophyllon and Geniſta bruſed and ſtamped: or elſe the hives muſt be compaſſed about in the middeſt with branches of the white Vine,

* Conſidering that of a beaſts carkaſſe they will be engendred.

for

for feare leaſt the Bees depart and flie away. The veſſels whereout honey hath beene emploied, G
yea, and honey combes, would bee well rinced and waſhed in water: which being throughly ſod-
den, maketh a moſt wholeſome and excellent vinegre.

As touching Wax, it is made of the combes after the honey is preſſed and wrung out of them. But firſt they muſt bee purified and cleanſed with water, and for three daies dried in ſome darke place: upon the fourth day they are to be diſſolved and melted upon the fire in a new earthen pot never occupied before, with ſo much water as will cover the combes: and then it ſhould be ſtrained through a panier of reeds or ruſhes: which done, the wax is to be ſet over the fire a ſecond time in the ſame pot, and with the ſelfeſame water, and ſodden againe; and then it ought to run out of it into other veſſels of cold water, but thoſe firſt ſhould be all about within annointed and beſmeared with honey. The beſt wax is that which is called Puniça, *i.* of Barbarie, and is H
white. The next in goodneſſe is the yelloweſt, and ſmelleth of honey, pure and cleane without ſophiſtication; ſuch commeth from the countrey of Pontus: and verely I wonder much how this wax ſhould hold good, conſidering the venomous honey whereof it is made. In the third place is to be raunged the wax of Candie: for this ſtandeth much upon that matter which they call Propolis, whereof I have alreadie ſpoken in the Treatiſe of Bees and their nature. After all theſe, the wax of the Iſle Corſyca may be reckoned in the fourth ranke: which becauſe it is made much of the Box tree, is thought to have a vertue medicinable. Now the making and working of the firſt and beſt Punicke white wax, is after this manner: They take yellow wax, and turne it often in the wind without the houſe in the open aire; then they let it ſeeth in ſea-water, and namely, ſuch as hath been ſet farre from the ſhore out of the very deepe, putting thereto Nitre: this done, they ſcum off the flower (that is to ſay, the whiteſt of it) with ſpoones; and this creame (as it were) I
they change into another veſſell, which hath a little cold water in it. Then once againe they boile it in ſea-water by it ſelfe alone, and ſet the veſſell by for to coole. After they have done thus three times, they let it drie in the open aire upon an hurdle of ruſhes, in the Sunne and Moone, both night and day: and this ordering bringeth it to be faire and white. Now, in the drying, for feare that it ſhould melt, they cover it all over with a fine Linnen cloth. But if they would have it to be exceeding white indeed, they ſeeth it yet once more, after it hath been thus ſunned & mooned. In truth, this Punicke white wax, is ſimply the beſt to be uſed about medicines. If one be diſpoſed to make wax blacke, let him put thereto the aſhes of paper: like as with an addition of Orchanet it will be red. Moreover, wax may bee brought into all manner of colours, for painters, limners, and enamellers, and ſuch curious artificers, to repreſent the forme and ſimilitude of any thing K
they liſt. And for a thouſand other purpoſes men have uſe thereof, but principally to preſerve their walls and armours withall. All other things as touching Honey and Bees, have ben handled alreadie in the peculiar Treatiſe to them and their nature belonging. Here an end therefore of Gardens and Gardinage.

Chap. xv.

Of hearbs which come up of themſelves, and ſuch eſpecially as be armed with pricks.

IT remaineth now to ſpeake of certaine wild hearbs growing of their own accord, which in many nations ſerve for the kitchin, and principally in Ægypt: for this countrey, although it bee L
moſt plentifull in corne, yet may ſeeme to have leaſt need thereof, and of all nations under heaven beſt able to live without the ſame: ſo well ſtored it is with hearbs, wherof the people doth ordinarily feed: whereas in Italie here, wee know as few of that kind good to be eaten, namely, Strawberries, * Tanus, Ruſcus, Creſtemarine or Sampire; as alſo Batis Hortenſiana, which
*The fruit or berrie whereof is *Vva Taminia*
ſome call French Sperage: we have alſo the wild Parſnep of the medows, and the Hop, but wee uſe them rather for pleaſure and delight, and to give contentment to our taſt, than for any neceſſarie food to maintaine life. But to come againe to Ægypt, there is to be found the nobleſt plant of all others, Colocaſia, which ſome name Cyamos, [*i.* the Ægyptian beane:] this hearbe they gather and cut downe out of the river Nilus: it putteth forth a maine ſtem, which being ſodden, M
yeeldeth in the eating and chewing, a certaine threadie matter or woolly ſubſtance, drawing out in manner of a cobweb; but the ſtalke as it groweth up amid the leaves, maketh a faire and goodly ſhew: for indeed the ſaid leaves be exceeding large, and comparable to the broadeſt that any tree beareth; reſembling thoſe for all the world of the Clote or great Burrhe growing in our ri-

A vers, which we call Perſonata. A wonderfull thing it is to ſee, what ſtore they in Ægypt ſet by the commodities that their river Nilus doth affourd: for of the leaves of this Colocaſia (plaited and enfolded naturally one within another) they make them cups of divers formes and faſhions, out of which they take no ſmall pleaſure to drinke. And now adaies this hearb is planted here in Italie. Next to Colocaſia, the Ægyptians make moſt account of that Cichorie, which I named before, the wild and wandring Endive; which hearbe commeth up in that countrey after the riſing of the Brood-hen ſtar: it floureth not all at once, but bloweth by braunches one after another: a ſupple and pliable root it hath, and therefore the Ægyptians uſe it in ſtead of cords to bind withall. As for Anthalium, it groweth not in Nilus, but not far from the river: it beareth a fruit in bigneſſe and roundneſſe reſembling a Medlar, having neither kernell within, nor huske with-
B out: and the leafe of this plant is like to Cyperus, or Engliſh Galangale. This hearbe they uſe to eat, being firſt * dreſſed and prepared in the kitchin. They feed likewiſe upon Oetum, a plant that hath few leaves and thoſe very ſmall, howbeit a great root. Touching Aracidna and Aracos, they have many roots verely braunching and ſpreading from them, but neither leafe nor herbage, ne yet any thing els appearing above ground. And thus much of the chiefeſt and greateſt hearbs of Ægypt, ſerved up to the table: The reſt are common or vulgar, and every mans meat, by name, Condrylla, Hypochœris, Caucalis, Authriſcum, Scandix, (called by ſome Tragopogon, which beareth leaves like to Saffron;) Parthenium, Strychnum, Corchorus, and * Apace, which ſheweth his head about the Æquinox: alſo Acinos, and that which they name Epipetron, and it never beareth floure; whereas Aphace contrariwiſe never giveth over flouring,
C but when one floure is faded and ſhed, another commeth up, and this courſe it holdeth all winter long; throughout the Spring alſo, even to the heat of Summer. Many other hearbs they have of baſe reckoning: but above all, they make greateſt account of * Cnicus (an hearbe not knowne in Italy) not for any good meat they find in it, but for the oyle drawne out of the ſeed thereof. Of this hearbe, there be two principall kinds, to wit, the Wild, and the Tame: the Wild is ſubdivided into two ſpeciall ſorts, the one of a more mild and gentle nature than the other; although the ſtalks of both be alike, that is to ſay, ſtiffe and ſtreight upright: and therefore women in old time uſed the ſtems thereof for rocks and * diſtaffs; wherupon ſome do call the hearb
D Atractylis: the ſeed is white, big, and bitter. The ſecond is more rough and hairie, creeping long on the ground, with ſtalks more muſculous and fleſhie, and carrieth a ſmall ſeed. This hearb may be raunged among thoſe that be prickly: for ſo muſt herbs be devided into ſuch generall head; namely, that ſome be full of pricks, others cleane without and ſmooth. As for thoſe which ſtand upon pricks, they be ſubdivided into many members and braunches. And to begin with a kind of Sperage, called alſo Scorpio, it hath no leafe at all, but in ſtead thereof, pricks and nothing els. Some there be leafed indeed, but thoſe are beſet with pricks, as the Thyſtle, Sea-holly, * Liquitice, and Nettle: for the leaves of all theſe hearbs be prickie and ſtinging withall. Others, beſides their leaves, have prickles alſo, as the * bramble, and Reſt-harrow or Whin. Some be provided of pricks both in leafe and ſtalke, as Phleos, which others have called Stœbe. As for Hippophacet, it hath a pricke or thorne in every joynt: but the bramble Tribulus aforeſaid, hath this
E propertie by it ſelfe, That the fruit alſo which it beareth, is ſet with pricks. Of all theſe ſorts, the Nettle is beſt knowne, which carrieth certaine goblets and concavities, and the ſame yeelding a purple kind of downe in the floure, and it riſeth up ſometimes above two cubits high. Many kinds there bee of theſe Nettles; namely, the wild Nettle, which ſome would have to be the female, and this is more mild than the reſt. In this wild kind is to be reckoned alſo, that which they call Cania, and is of the twaine more ægre, for the verie ſtalke will ſting, and the leaves be purfled as it were and jagged. But that Nettle which carrieth a ſtinking ſavor with it, called is Herculanea. All the ſort of them are full of ſeed, and the ſame blacke. A ſtraunge qualitie in theſe Nettles, that the verie hairie down of them (having no evident pricks ſticking out) ſhould be ſo
F ſhrewd as it is, that if one touch it never ſo little, preſently there followeth a ſmarting kind of itch, and anon the skin riſeth up in pimples and bliſters, as if it had been skalt or burnt: but well knowne is the remedie of this ſmart, namely, to annoint the place with oile. Howbeit this biting propertie that it hath, commeth not to it at the beginning when it is new come up, but it is the heat of the Sun that fortifieth this mordacitie. And verely in the Spring when the Nettle is yong and peepeth firſt out of the ground, they uſe to eat the crops thereof for a pleaſant kind of meat, and many be perſuaded beſides that it is medicinable, and therefore preciſely & religiouſly ſeed

* as *Theophraſtus* ſaith, ſodden in ale: *hordeaceo zytho.*

* Thought to be *Dent de lion.*

* *Carthamus*, or baſtard ſaffron: but *Turnebus* ſuppoſeth it to be put for *Cieti*, whereof commeth *Oleum Cicinum.*

* *Celu*, although ſome read *fuſis*, *i.* ſpindles.

* *Glycyrrhizen*, but this agreeth not with our Liquitice.

* *Tribulus.*

* *Acetabulis.*

thereupon, as a preſervative to put by all diſeaſes for that preſent yeare. Alſo the root of the wild Nettle, if it be ſodden with any fleſh, maketh it to eat more tender. The dead Nettle, which ſtingeth not at all, is called Lamium. As touching the hearbe Scorpio, I will write in the treatiſe of hearbs medicinable. G

Chap. XVI.

Of Carduus, and Ixine: of Tribulus and Anchuſa.

THe common Thiſtle is full of prickie haires, both in leafe and ſtalke: likewiſe *Acorna, *Leucacanthos, Chalceos, Cnicos, Polyacanthos, Onopyxos, Ixine, and Scolymos. As touching the Thiſtle Chamæleon, it hath no pricks in the leafe. Moreover, theſe prickie hearbs are diſtinguiſhed & different one from another, in this, That ſome of them be furniſhed with many ſtems, and ſpred into divers braunches, as the Thiſtle: others againe riſe up with one maine ſtalke, and branch not, as Cnecos. Alſo there be of them that be prickly only in the head, as the Eryngium or Sea-holly. Some floure in Summer, as Tetralix and Ixine. As for Scolymus, late it is alſo ere it blow, but it continueth long in the floure. Acorna differeth from it onely in the red colour and fattier juice that commeth from it. Atractylis alſo might goe for Scolymus, but that it is whiter and yeeldeth a liquor like bloud: whereupon there be ſome who call it Phonos, *i.* Murderer: this qualitie it hath beſides, that it ſenteth ſtrong: the ſeed alſo ripeneth late, and not before Autumne: and yet this is a propertie common to all plants of this prickie and thiſtly kind. But all theſe hearbs will come of ſeed and root both. As for Scolymus, it differeth from the reſt of theſe Thiſtles herein, That the root, if it be ſodden, is good to be eaten: beſides, it hath a ſtraunge nature, for all the ſort of them during the Summer throughout, never reſt and give over, but either they floure, or they apple, or els be readie to bring foorth fruit: and looke when the leaves begin to wither, their pricks looſe their force and will not pierce. H I

* A kind of thiſtle: ſome call it Mans-bloud.
* S. *Mary* thiſtle.

Ixine * is a rare hearbe and geaſon to be ſeene, and not found growing in all countries alike. Immediatly from the root it putteth foorth leaves plentie; out of the mids of which root there ſwelleth out a bunch like an apple, but the ſame is covered with the foreſaid leaves: in the verie top of which fruit, there is contained a gum of a pleaſant taſt, called the Thiſtle-Maſticke. Touching the hearbe Cactos, which groweth alſo in Sicilie and no where els, it hath a propertie by it ſelfe; the ſtalkes whereof ſhooting from the root, creepe along the ground, and it carrieth a broad leafe full of pricks and thorns: and indeed theſe ſtalks thus running upon the earth, the Sicilians call Cactos, which they uſe to keep and preſerve; and being thus condited alſo, they commonly eat, as very good meat. One ſtem it hath growing upright, which they tearme Pternix, as ſweet and pleaſant as the other, but it will not abide to be kept long. The ſeed thereof is covered with a certaine ſoft downe, which they call Pappos, which being taken off with the huske, there remaineth a tender kernell within, which they eat, and find it as delicat as the verie heart of the Date tree top, which is called the Braine: and this pith aforeſaid, the Sicilians name Aſcalia. K

* *Non rara viſum eſt, æquè in omnibus terris naſcitur: Ex Theop.* which is clean contrary to *Plinie.*

The Caltrop-thiſtle Tribulus, groweth not but in moorie grounds and ſtanding dead waters. Surely in other places, folke curſe it as they paſſe by, the pricks and ſpurs ſticke out ſo daungerouſly: but about the rivers Nilus and Strymon, the inhabitants do gather it for their meat. The nature of this plant, is to leane and bend downward in the head to the water: the leafe reſembleth in forme thoſe of the Elme, and they hang by a long ſtele or taile. But in other parts of the world there be two other kinds of Tribulus: the one is leafed like to the Cichling peaſe; the other hath leaves ſharpe pointed: this ſecond kind is later ere it floure, and commonly groweth about the mounds of cloſes lying by villages and towne ſides; the ſeed lyeth in a cod rounder than the other, and blacke withall: whereas the former hath a * ſandie ſeed. Of theſe thornie and prickly plants, there is yet one kind more, namely Ononis, *i.* Reſt-harrow: for it carrieth pricks cloſe to the very braunches: the leafe is like to Rue: the whole ſtalke throughout is ſet with leaves diſpoſed in manner of a guirland. This plant commonly groweth after corn; it * plagueth the plough, and yet there is much adoe to rid it out of a ground, ſo loth it is to die. Of plants that be prickie, ſome have their ſtalkes and braunches training by the ground, as namely that hearbe which they call Coronopus, *i.* Harts-horne, or Buck-horne Plantain: contrariwiſe, there ſtand upright, Orchanet, the root whereof is ſo good to colour wax and wood red. And of ſuch as be more gentle in handling * Camomile, Phyllanthus, Anemone, and Aphace. As for Crepis and * Apate, their L M

* ἀνιμῶδες, for, ἀνθεμῶδες, *in Theophraſt.* *i.* like the ſeed of Seſama.
* And therfore it is called, *reſta bovis*, or *reſta aratri*, becauſe it ſtaieth the draught of the Oxe at plough.
* *Anthemius.*
* Deceit: ſo called, becauſe the bitternеſſe deceiveth many a one, looking like to a kind of Cichorie.

ſtalks

A ſtalks be all leafe. Moreover, this would be noted, that the leaves of hearbs differ one from another, as well as in trees: ſome in the length or ſhortneſſe of the ſtele whereto they hang; others in the breadth or narrowneſſe of the leafe it ſelfe: in forme alſo, whereby you ſhall have ſome cornered, others cut and indented: likewiſe in ſent and floure, for ſome there be that continue longer in flouring than others, and blow not all at once, but one part after another, as Baſill, Tornſoll, Aphaca, and Onocheile.

Chap. xvii.

The difference of hearbs in their leafe: what hearbs they be that floure all the yeere long: of the Aſphodel, Piſtana, and petie Gladen or Sword-graſſe.

B MAny hearbs there be as well as ſome trees, which continue greene and hold their leaves from one end of the yeare to the other, as Tornſoll, and Adianthum or Capillus Veneris. Another ſort there is of hearbs that floure ſpike-wiſe, of which kind are Cynops, Alopecurus, [*i.* Foxtaile,] Stelephuros, which ſome call Ortyx, others Plantaine, (of which I will write more at large among Phyſicke hearbs) and Thryollis. Of theſe, Alopecurus carrieth a ſoft ſpike, and a thick moſſie down, not unlike to Fox tails, whereupon it tooke that name in Greeke: and Stelephurus reſembleth it very much, but that the Foxtaile bloweth not all togither, but beareth floures ſome at one time & ſome at another. Cichorie and ſuch like, have their leaves ſpreading upon the ground, and thoſe put foorth directly from the root, beginning to ſpring immediatly after the apparition of the ſtarre Vergiliæ. As touching Parietarie, there be other nations
C as well as the Ægyptians, who feed upon it: It tooke the name Perdicium in Latine, of the bird Perdix, *i.* the Partridge, that ſeeketh after it ſo much, and plucketh it out of the wals where it groweth: it hath many roots and the ſame thicke. In like manner, the hearbe Ornithogale, *i.* Dogs oinion, hath a ſmall ſtem and a white, but a root *halfe a foot long, the ſame is full of Bulbes like oinions, ſoft alſo, and accompanied with three or foure other ſpurs growing out of it. This hearb they uſe to ſeeth among other pot-hearbes for pottage. I will tell you a ſtraunge qualitie of the hearbe Lotos and of Ægilops: if their ſeed be caſt into the ground, it will not come up in a year. As wonderfull is the nature alſo of the Camomile: for it beginneth to flower in the head, whereas all other hearbes which blow not all at once, flower at the foot firſt. Notable is the Bur likewiſe
D and worthie to be obſerved, I meane that which ſticketh to our clothes as we paſſe by, the flower lieth cloſe and groweth within the ſaid Bur, and never appeareth without-foorth: it is I ſay as it were hatched within, much like to thoſe living creatures that couve and quicken their egs within their bellie. Semblably, about the cittie Opus there is an hearbe called Opuntia, which men delight to eat: this admirable gift the leafe hath, That if it be laid in the ground, it will take root; and there is no other way to plant this hearbe, and maintaine the kind. As for Iaſione, one leafe it hath and no more: but ſo lapped and enfolded, that it ſeemeth as if they were many. Touching Condrylla, the hearbe it ſelfe is bitter: but the juice of the root is hote and biting. Bitter alſo is Aphaca or Dent de Lion: as alſo that which is called Picris, which name it tooke of the exceeding bitterneſſe that it hath; the ſame floureth all the year long. As for Squilla and Saffron, they
E bee both of a marveilous nature: for whereas all other hearbs put out leafe firſt, and then knit round into a ſtem, in theſe two a man may evidently ſee the ſtalk before the leafe. And in Saffron verely, the ſaid ſtalke thruſteth out the floure before it: but in the Sea-onion Squilla, firſt ſheweth the ſtalke, and then afterwards the floure breaketh out of it. The ſame Squilla floureth thrice in the yeere, as I have ſaid heretofore, ſhewing thereby the three ſeaſons of ſeednes. In the range of theſe bulbous and onion-rooted plants, ſome place the root of * Cyperus, that is to ſay, of Gladiatus, [*i.* Petie-gladen, Flags, or Sword-wort:] this is a ſweet root, and being ſodden or baked with bread, it giveth it a more pleaſant taſt; and beſides, it mendeth the weight of bread well if it be wrought & kneaded with it in dough. Not unlike to it is that hearbe which they call Theſion, but that the root is harſh and unpleaſant. All others of the ſame kind differ in leafe. The As-
F phodell hath long and narrow leaves: Squilla is broad leafed, and may be handled without offence; whereas the Gladen leafe is like a ſword blade indeed, and keene-edged according to the name [both in Greeke and Latine.] The Aſphodell ſeed is good to be eaten, if it be parched or fried: ſo is the bulbous root of it alſo; but this ſhould be roſted under the embres, and then eaten with ſalt and oile: Over and beſides, if it be ſtamped with figs, it is an excellent diſh; and this

* *Semipedali.* Dioſcor. hath *Seſquipedali, i.* a foot and a halfe.

* *Cyperi*, or rather *Xyphij*, or *Phaſgani.*

indeed (according to *Heſiodus*) is the onely way to dreſſe it. Moreover, it is ſaid, that Aſphodels G
planted before the gates of any ferme houſe in the countrey, preſerve the place from all charms and ſorceries. *Homer* alſo the Poët hath made mention of the Aſphodell. The root reſembleth
**Napis*: Dioſcor. *Glandibus, id eſt*, nuts or acorns. **Navews of a meane bigneſſe: and there is not another root with more heads, for oftentimes a man ſhall ſee foureſcore bulbs cluſtred in a bunch togither. *Theophraſtus*, and all Greeke writers almoſt, and namely *Pythagoras* (the chiefe prince of Philoſophers) deſcribe this plant to have a ſtem of one cubit in length, yea and oftentimes of twaine; with leaves like to wild Porret: and the ſaid ſtem they called Anthericon; but the root, that is to ſay, thoſe bulbs reſembling onions, Aſphodelas: but our countreymen have named in Latine, the ſtem Albucus; but the root, Haſtula Regia. This is the name alſo of the ſtalke, full of grains or berries: and thereof they would make two kinds [the male and female.] Well, the ſtem of the Aſphodell then, is commonly a cubit long, large and big, cleane and ſmooth. Of this hearbe *Mago* hath written, and ordained, that it ſhould be cut downe in the going out of March and entrance of Aprill, namely, after it hath done flouring, and before that the ſeed be ſwelled and growne to any bigneſſe: then upon the fourth day after, when the ſaid ſtems are ſlit and cloven, they muſt be laid abroad to dry in the Sun: when they be dried, they ought to be made up into knitchets or handfuls. Hee ſaith moreover, that the Greeks name that hearbe Piſtana, which we call in Latine Sagitta, growing in mariſhes and moores among other fennie weeds. This alſo would he have to be cut down and gathered, betweene the Ides of May and the end of the month of October: then, to bee pilled, and ſo to be dried by little and little with the moderat heat of the Sun. The ſame author giveth order like wiſe, that the other kind of Gladiolus, which they call Cypiros, which alſo is an hearb I
growing about lakes and meeres, any time within Iuly ſhould be cut downe to the very root; and the third day after, to be dried in the Sun untill it looke white: but every day that it lyeth abroad, it muſt be brought into the houſe before the Sun goe downe; becauſe all hearbs growing upon mariſh grounds, take harme by dewes in the night.

Chap. xviii.

Of Ruſhes, ſix kinds; and of Cyperus: their medicinable vertues. Of Cypirus, and the ſweet ruſh Scœnanth.

Mago writing of the Ruſh, commonly called Mariſcon, ſaith, That for to twiſt and weave K
into mats, it ought to be gathered out of the mariſh ground where it groweth, in Iune untill mid-Iuly. As for the drying of it, the ſame order muſt be obſerved in all points, as we have ſet downe before in the diſcourſe of other marais weeds. He maketh a ſecond kind of water Ruſhes, which I find to be called the Sea-ruſh, and of the Greeks Oxyſchœnon, *i.* the Sharpe ruſh: which alſo is ſubdivided into three other ſorts; for there is the barraine ruſh, called alſo the male, and in Greeke Oxys: the female Ruſh bearing a blacke ſeed, which they call Melancranis. This is thicker than the other, fuller alſo of braunches and tufts. And the third more than it, which is named Holoſchœnus. Of all theſe, Melancranis commeth up of the own ſeed, without any other kinds intermingled with it: but Oxys and Holoſchœnus, grow both togither out of one turfe. Of all others, the great Ruſh Holoſchœnus is beſt for to be wrought in mats, & ſuch L
like implements about an houſe, becauſe it is ſoft and fleſhie: it beareth a fruit hanging and cluſtering togither in manner of fiſh ſpawne. As for that Ruſh, which we called the male, it groweth of it ſelfe, by reaſon that his top faſteneth in the ground, and ſo taketh root by way of propagation: but Melancranis ſoweth her owne ſelfe, and commeth up of ſeed; for otherwiſe their race would periſh, conſidering the roots of them all every yeere doe die. Theſe Ruſhes are uſed to make leaps and weels for fiſhers at ſea, and fine and daintie wicker veſſels: alſo candle-wick and matches; eſpecially the marow or pith within, which is ſo great (eſpecially about the foot of the Alps reaching to the ſea ſide) that when a Ruſh is ſlit, there is found in the belly a pith almoſt an inch broad by the rule. And in Ægypt there be found Ruſhes ſo big, that they will ſerve to make ſieves, rangers, and vans: in ſuch ſort, that the Ægyptians can find no matter for that purpoſe, M
better. Some there be, that would have the triangled or three ſquare ruſh Cyperus, to be a ſeverall kind by it ſelfe. This Cyperus, many there be that cannot diſtinguiſh from Cypirus, by reaſon of the great affinitie of their two names: but I meane to put a difference betweene them both: for Cypirus is the Petie-glader or Sword-graſſe, (as I have before ſhewed) with a bulbous

or

A or onion-root: the beſt of which kind, groweth in the Iland of Crete: next to it in goodneſſe, is that of the Iſle Naxos: and in a third degree, is to be placed that of Phœnice: and indeed that of Crete or Candie, in * whiteneſſe and odour commeth neare to Nard. The Naxian Cypirus hath a quicker ſent: the Phœnician Cypirus ſmelleth but a little. As for that in Ægypt, it hath no ſavour at all; for there alſo groweth Cypirus. But now to come unto the properties thereof, it hath vertue to diſcuſſe and reſolve hard ſwellings in the bodie. For now my purpoſe is to ſpeake of their medicinable vertues, for as much as there is great uſe in Phyſick, as well of ſuch aromaticall ſimples, as odoriferous floures. As touching Cypirus therefore, I profeſſe verely that I will follow *Apollodorus*, who forbiddeth expreſſely to take Cypirus inwardly in any drinke: and yet he proteſteth, that it is moſt effectuall for them that be trobled with the ſtone, and full of gravell;

B but, by way of fomentation onely. Hee affirmeth moreover, that without all doubt it cauſeth women to travaile before their time, and to ſlip their untimely fruit. But one miraculous effect thereof he reporteth, namely, That the Barbarians uſe to receive the fume of this hearbe into their mouth, and thereby waſt and conſume their ſwelled ſplenes: alſo, they never go forth of dores, before they have drunke a pipe thereof in that manner: for perſuaded they are verely (ſaith hee) that by this means they are more youthfull, lively, and ſtrong. He ſaith moreover, that if it be applied as a liniment with oile, it healeth all merry-galls and raw places where the fleſh is rubbed off or chafed: it helpeth the ranke rammiſh ſmell under the arme-holes; and without faile cureth any chilling, numneſſe, and through-cold. Thus much of Cypirus.

As for Cyperus, a Ruſh it is (as I have ſaid) growing ſquare and cornered: neare the ground

C it is white; toward the top, of a darke blackiſh greene, and fattiſh: the under-leaves that be loweſt, are ſlenderer than leeke-blades: the uppermoſt in the head, are ſmall, among which is the ſeed. The root is like unto a blacke Olive, which if it grow long-wiſe, is called Cyperis, and is of ſingular operation in Phyſicke. The beſt Cyperus is that which groweth among the ſands in Africke, neare the temple of *Iupiter Ammon*: in a ſecond ranke, is that of Rhodes: in a third place may be raunged the Cyperus in Thracia: and in the loweſt degree, that of Ægypt. And hereupon came the confounding of theſe two plants, Cyperus and Cypirus, becauſe both the one and the other grow there. *But the Cyperus of Ægypt is very hard, and hath no ſmell at all; whereas in the other, there is a ſavour reſembling the very Spikenard. There is another hearbe alſo comming from the Indians, called * Cyperis, of a ſeverall kind by it ſelfe, in forme like vnto

D Ginger: if a man chew it in the mouth, it coloureth the ſpittle yellow, like as Saffron.

But to come again to Cyperus, and the medicinable properties therof, It is counted to have a depilatorie vertue for to fetch off haire. In a liniment it is ſingular good for the excreſcenſe of the fleſh about the naile roots, or the departure and looſeneſſe thereof about them; which both imperfections be called Pterygia: it helpeth the ulcers of the ſecret parts, and generally all exulcerations proceeding of rheumaticke humors, as the cankers in the mouth. The root of Cyperus is a preſent remedie againſt the ſtinging of ſerpents, and ſcorpions eſpecially. Taken in drinke it doth deſopilat and open the obſtructions of the matrice: but if a woman drink too much thereof, it is ſo forcible that it will drive the matrice out of the bodie. It provoketh urine, ſo as it expelleth the ſtone and gravell withall: in which regard alſo, it is an excellent medicine for the dropſie.

E A liniment thereof is ſingular for cancerous and eating ſores, but eſpecially for thoſe that be in the ſtomacke, if it be annointed with wine or vinegre tempered with it.

As concerning the Ruſhes beforeſaid, their root ſodden in three hemines of water, untill one third part be conſumed, cureth the cough. The ſeed parched againſt the fire, and ſo drunke in water, ſtaieth the flux of the belly, and ſtopperh the immoderat courſe of womens monthes; but it procureth headach. As for the Ruſh called Holoſchœnos, take that part of it which is next the root, and chew it; then lay it to the place that is ſtung with a venomous ſpider, it is an approved remedie. I find one ſort more of Ruſhes, which they call Euripice; and this propertie withall, That it bringeth one to ſleepe: but it muſt be uſed with moderation, for otherwiſe it breedeth drowſineſſe, lib to the lethargie. Nowſeeing I am entred into the treatiſe of Ruſhes, I muſt needs

F ſet downe the medicinable vertues of the ſweet Ruſh called Squinanth; and the rather, becauſe (as I have alreadie ſhewed) it groweth in Syria ſurnamed Cœle. The moſt excellent Squinanth commeth out of Nabatœa, and the ſame is knowne by the addition or ſurname Teuchites. In a ſecond place is that of Babylon. The woorſt of all is brought out of Affricke, and it is altogether without ſmell. Squinanth is round, of an hote and * fierie taſt, biting at the tongues end.

* *Candor*: ſome read *Color*: i. in colour.

* No more hath *Cypirus* in Ægypt, by his owne ſaying.

* This *Cyperis* is taken to be *Curcuma*, or *Terramerita*, called thereupon corruptly, *Turmericke*.

* *Ignea mordacitatis.*

The true Squinant indeed which is not ſophiſticated, if a man rub it hard, yeeldeth the ſmell of a Roſe: and the fragments broken from it, doe ſhew red. As touching the vertues thereof, It reſolveth all ventoſities, and therefore comfortable it is and good for the wind in the ſtomacke: alſo it helpeth them that puke up choller, or reach and ſpit bloud: it ſtinteth the yex, cauſeth rifting and breaking wind upward: it provoketh urine, & helpeth the bladder. The decoction therof is good for womens infirmities, if they ſit therein. A cerot made therewith, and drie roſin together, is excellent againſt ſpaſmes and cricks that ſet the necke far backward. G

As concerning Roſes, the temperature thereof is hot: howbeit they knit the matrice by an aſtrictive qualitie that they have, and coole the naturall parts of women. The uſe of Roſes is twofold, according to the leafe of the floure, and the floure it ſelfe (which is the yellow.) The head of the Roſe leafe, to wit, the white part thereof, is called in Latin Vnguis, *i.* the Naile. In the yellow floure aforeſaid, are to bee conſidered ſeverally, the ſeed, the hairie threads in the top, the huske and pellicle that covereth the roſe in the bud, and the cup within: and every one of theſe have their proper qualities and vertues by themſelves. The leaves are dried, or the juice is drawn and preſſed out of them three waies: either all whole as they be, without clipping off the white nailes, for therein lyeth the moſt moiſture: or when the ſaid nailes are taken off, and the reſt behind is infuſed in the Sun, lying either in wine or oyle within glaſſes, for oile roſat or wine roſat. Some put thereto ſalt, others mingle withall either Orchanet or Aſpalathus, or els Squinanth: and this manner of juice thus drawne and prepared, is very good for the matrice, and the bloudie flix. The ſame leaves, with the whites taken away, are ſtamped, and then preſſed through a thicke linnen cloth into a veſſell of braſſe; and the ſaid juice is ſodden with a ſoft fire unto the conſiſtence of hony: and for this purpoſe, choiſe would be made of the moſt odoriferous leaves. H I

Chap. xix.

The medicinable vertues of Roſes: of the Lillie and Daffodill, called Laus tibi. Of the Violet, of Bacchar, Combretum, and Azarabacca.

HOw wine of Roſes ſhould be made, I have ſhewed ſufficiently in the treatiſe of divers kinds of wines. The uſe of the juice drawne out of Roſes, is good for the eares, the cankers, and exulcerations in the mouth, the gumbs, the Tonſils or Amygdals, for gargariſms, for the ſtomacke, the matrice, the infirmities and accidents of the tuil or fundement, and the head-ach. Taken alone, it is ſingular good for the ague; with vinegre, for to procure ſleepe, and to reſtraine the heaving of the ſtomacke, and the offers to vomit. The aſhes of Roſes burnt, ſerve to trim the haires of the eyebrowes. Roſes dried and reduced into powder, repreſſe the ſweat betweene the *legs, if it bee ſtrewed upon the place. Dried Roſe leaves doe repreſſe and ſtay the flux of humors into the eyes. The floure [which is the yellow in the mids] procureth ſleepe. The ſame taken inwardly with vinegre and water, ſtayeth the immoderat flux of women; and the whites eſpecially: alſo it repreſſeth the reaching and ſpitting of bloud. The pain of the ſtomack it appeaſeth, being taken in three cyaths of wine. The ſeed or fruit of the Roſe (which is of a Saffron colour) is beſt, ſo it be not above a yeare old, and the ſame dried in the ſhade. As for the blacke, it is naught and good for nothing. To rub the teeth with this ſeed, eaſeth the toothach: the ſame provoketh urine. Being applied to the ſtomack, it is comfortable: & ſo it helpeth S. *Anthonies* fire, if it hath not run too long. If it be drawn up by the noſthrils, it purgeth and cleanſeth the head. As for the heads or knobs, if they be taken in drinke, they knit and bind the bellie, and withall, doe ſtay the flux of bloud upward. The whites or nailes of the Roſe leafe bee ſingular for wateriſh eies, ſo they be applied drie with bread crums. The leaves verely if they be brought onely into a liniment, and outwardly applied, are reputed ſoveraigne for the queaſineſſe and paine of the ſtomack, for the gnawings and other accidents which the bellie and guts bee ſubject unto: alſo for the Midriffe and other precordiall parts. Moreover, they are good to be eaten, if they be condite and preſerved in manner of garden Docke or Patience. But in keeping of Roſe leaves, an eye would be had unto them, for fear leaſt they grow to a mouldineſſe, which quickly will ſettle upon them. Drie Roſe leaves are of good uſe in Phyſicke, yea, the very Roſe cake after the juice and moiſture is preſſed out of the leaves, ſerveth for ſome purpoſe. For of them be made bags and quilts, yea, and drie pouders for to repreſſe ſweat, and to palliat the ſtrong ſmell therof: with this charge and caveat, that preſently after that one is come out of the ſtouve or baine, the pouder bee ſuffered to drie K L M

upon

* *Siccis fœmina aſperguntur*: I doubt that *Plinie* read in *Dioſcorides*, μυρσίνη for μύρτα, *id eſt*, *Vnguenta*: and then it carieth this ſenſe; that dried Roſes & powdered, enter into ſweet ointments.

A upon the bodie, and then afterward waſhed off with cold water. The wild Roſe *leaves reduced into a liniment with Beares greaſe, doth wonderfully make haire to grow again, where (through ſome diſeaſe) it is fallen away.

*or rather the ſpungie ſubſtance growing upon the Cancre brier and wild Roſe.

Lillie roots through their ſingular vertues and operations many waies, have enobled their own flowers. For firſt and formoſt, if they be taken in wine, they bee countrepoyſons againſt the ſting of Serpents, and the venome of Muſhromes. Sodden in wine, and applied in manner of a cataplaſme, and ſo bound to the feet, they mollifie and reſolve the cornes: but this muſt not bee undone and removed in three daies. Boiled with greaſe or oile, they cauſe hair to come again even in places that were burnt. If Lillie roots bee drunke in honied wine, they doe evacuat downeward at the ſeege with other ordure, the cluttered, bruiſed, and hurtfull bloud within the bodie. Over
B and beſides, in this manner they helpe the ſpleene, them that are burſten and bruiſed, and withall, bring downe womens tearmes orderly. But if they be ſodden in wine, and ſo laid too in forme of a cataplaſme, they knit and heale ſinewes that were cut aſunder. They rectifie running tetters and lepries: they ſcoure away dandruffe and pilling skales in the face, they make the skin ſmooth and take away rivels and wrinckles. The leaves of Lillies boiled in vinegre, are good to be laid to greene wounds: reduced into a cataplaſme with Hony, Henbane, and Wheat meale, incorporat and united all together, and ſo applied to the cods, they repreſſe the flux of humours falling to thoſe parts. The ſeed made into a liniment, allaieth the heat of S. *Anthonies* fire. And in the ſame ſort, the flower and leaves applied, doe heale old ſores. As touching the juice, which is expreſſed forth of the flowers, of ſome it is called Mel, [*i.* Honey;] of others Syrium: ſingular good for
C to ſoften and mollifie the Mattice, for to procure ſweat, and to ripen impoſtumes tending unto ſuppuration.

Now for Daffodils, there be two kinds of them admitted by the Phyſicians for to bee uſed in medicine: the one with a purple flower; the other of a graſſe greene. This latter Daffodill is adverſe and hurtfull to the ſtomacke, and therefore cauſeth it to overturne and vomit: it ſetteth the bellie alſo into a flux: contrarie it is to the ſinewes, and ſtuffeth the head: for the which narcotike qualitie of ſtupifying & benumming the ſences, it tooke the name in Greek Narciſſus, of Narce; which betokeneth nummedneſſe or dulneſſe of ſence, and not of the young boy *Narciſſus*, as the Poets doe faine and fable. The roots as well of the one as the other Daffodill, have a pleaſant taſt (as it were) of honied wine: the ſame is good for burnes, applied unto the place with a little
D honey: and ſo it helpeth diſlocations and healeth wounds. Moreover, a cataplaſme made of it honey and oatmeale, doth reſolve or ripen biles and great apoſtemations: and in that ſort it draweth forth ſpils, ſhivers, arrow heads, and thornes, and whatſoever ſticke within the bodie? Being ſtamped and incorporat with Barley groats and oile, it cureth them that be bruiſed and ſmitten with a ſtone. Mingled with meale, it cleanſeth wounds, it ſcoureth the skin from all ſpots that disfigure it, yea, and taketh away the blacke morphew. Of this flower is made the oile Narciſſinum, good to ſupple and ſoften all hard tumors, good alſo to revive and heat again whatſoever is ſtark and benummed with extream cold. And above all, this flower is excellent for the eares: howbeit it maketh the head to ake.

Of Violets, there be ſome wild and of the field: others domeſticall, and growing in our gar-
E dens. The purple Violets are refrigerative and doe coole. And therefore a good liniment is made of them to be applied unto an hot ſtomacke, againſt burning inflammations. A frontall likewiſe may be made of them to bee laid unto the forehead. But a peculiar vertue they have beſides to ſtay the running and waterie eyes: as alſo to helpe the providence or falling downe both of uuill
F and matrice, and to reduce them againe into their places. Moreover, beeing applied to ſwellings and impoſtumations, they reſolve the ſame without any head or ſuppuration. Guirlands being made of Violets and ſet upon the head, reſiſt the heavineſſe of the head, and withſtand the overturning of the braines upon over-liberall drinking; yea, the very ſmell thereof will diſcuſſe ſuch fumes and vapours as would trouble and diſquiet the head. Violets being drunk with water, doe cure the Squinancie. That which is purple in the flower of the Violets, helpeth the falling evill, in children eſpecially, if they drinke it with water. Violet ſeed reſiſteth the poyſon of Scorpions. Contrariwiſe, the flower of the white Violet, to wit, the bulbous ſtocke-Gillofre, is good to breake all impoſtumate ſwellings, whereas March Violets did reſolve them. But as well the white Violets as the yellow wall-flowers are ſingular good to extenuate the groſſe bloud of womens tearmes, and to move urine. Violets if they be freſh and new gotten, are not ſo effectuall for theſe

purpoſes as the drie and old gathered, and therefore they would have a whole yeares drying before they be uſed. The wall-flower being taken to the quantitie of halfe a cyath in three cyaths of water, ſtirreth womens fleurs, and draweth them downe. A liniment made with the root and vinegre together, doe mittigat and allay the paine of the ſpleene: likewiſe it aſſuageth the gout: and being tempered with Myrrhe and Saffron, it is ſingular for inflammations of the eyes. The leaves mixed with honey, cleanſe the head from skurfe and skall: reduced into a cerot, it healeth up the chaps in the ſeat or fundament, as alſo all ſuch Fiſſures in any moiſt place whatſoever. And with vinegre they be good for all collections of humors and apoſtemations. G

Bacchar alſo is an hearbe whereof there is good uſe in Phyſicke. Some of our countreymen have called it in Latine Perpenſa. It aſſourdeth a good remedie againſt Serpents: it qualifieth the exceſſive heat of the head, allaieth the ach, and reſtraineth the flux of humors downe into the eyes. A cataplaſme is made therof for womens breaſts ſwelling immediatly upon childbirth, for to breake the kernell; alſo for fiſtulous ulcers beginning to breed between the corners of the eyes and the noſe; and S. *Anthonies* fire. The very odour thereof is a good inducement to ſleepe. The root ſodden and taken in drinke, is ſingular for them that are troubled with crampes & convulſions; that have fallen from on high; that be drawne together with ſpaſmes; and finally, for ſuch as labour for wind. A decoction made of three or foure of the roots, boiled away to the thirds, is given with good ſucceſſe for an old cough. And this drinke or Iuleb is very convenient for to purge women that have travelled and beene delivered before their time. It taketh away the ſtitches in the ſide, cureth the pleuriſie, and skoureth the ſtone. Hereof be bags and quilts made, and thoſe if they bee laid in a Ward-robe amongſt clothes and apparrell, cauſeth them to ſmell ſweet. H I

As for Combretum (which I ſaid was much like unto Bacchar) if it be beaten to pouder, and tempered with Hogs greaſe, it maketh a ſoveraigne ſalve that healeth wounds wonderfully. Aſarum (by report) is an appropriat medicine for the liver, if an ounce of it be taken in one hemine of honied wine. It purgeth the bellie as violently as Ellebore. In caſe of the Dropſie it is ſingular; as alſo for the Midriffe, precordiall parts, the Matrice, and the Ianiſe. If it bee put into new wine when it worketh, and ſo tunned up, it maketh a ſingular diureticke wine for to provoke urine: It muſt for this purpoſe be digged out of the ground, when the leaves begin to put forth. Dried it ought to be in the ſhade: although it be ſubject to corruption, and mouldeth very ſoone.

Chap. xx. K

Of *French Nard*, and *Saffron*. The medicinable vertues of Saffron, and the cake or dregs thereof. Of Saliunca, Polium, and Flower-de-lis. Of Holochryſon, Chryſocome, and Melilote.

FOr as much as ſome have taken ruſticke Nard to be the root of Bacchar, and ſo named it: the which hath put me in mind of French Nard, and the promiſe which I made in my treatiſe of ſtrange and forraine trees, to put off no longer than this place for to ſpeake of it, and the properties thereto belong. To acquit my ſelfe therefore, I will here ſet downe the vertues of the ſaid Nard, as touching Phyſicke. Firſt therefore, if two drams of French Nard bee taken in wine, it is ſingular againſt the ſting and biting of Serpents. *Item*, If one drinke it either in wine or water, it eaſeth the paſſions of the Collicke, proceeding from the inflammation of the gut Colon. In like ſort it cureth the inflammation of the liver and the reines: the overflowing alſo of the gall and the laundiſe therupon. Taken alone by it ſelfe or with Wormewood, it is a good remedie for the Dropſie. It repreſſeth the immoderat flux of womens flowers. L

Zedoarium. As touching Setwall or Valerian, which in the foreſaid place we named Phu; the *root either beaten into pouder or ſodden and ſo given in drinke, is excellent for the riſing of the Mother, which threateneth ſuffocation; for the paines of the breaſt and pluriſie. The ſame provoketh the courſe of womens tearmes, ſo it be taken in wine.

Saffron will not reſolve nor be mixed well with honey or any ſweet thing. Howbeit, in wine or water it will diſſolve very ſoone and be incorporated therwith. A ſoveraigne ſpice this is, and ſingular for many maladies. The beſt way to keepe Saffron, is within a box of horne. It diſcuſſeth verely all inflammations, but principally thoſe of the eyes, if together with an egg it bee applied in forme of a liniment. Excellent it is for the ſuffocation of the matrice, the exulcerations M

of

A of the ſtomacke,breaſt,kidneies,liver,lungs,and bladder: and more particularly,if any of theſe parts be inflamed,a proper remedie alſo it is in that caſe. Likewiſe it cureth the cough and pleuriſie.It killeth an itch,and provoketh urine. Our wine-knights when they purpoſe to ſit ſquare at the taverne and carouſe luſtily, if they drinke Saffron, never feare ſurfeit nor the overturning of
F their braine: and they are verely perſuaded, that this keepeth them from drunkenneſſe, and maketh them carie their drinke well. Certes, a Chaplet of Saffron upon the head, dooth allay the fumes aſcending up thither,and prevent drunkenneſſe. Saffron induceth ſleepe, but it troubleth the braine *ſomewhat. It pricketh forward to wanton luſt. The flower of Saffron reduced into a liniment with white Fullers earth,helpeth the Shingles and S. *Anthonies* fire. And Saffron it ſelfe entereth into very many compoſitions of Phyſicke.One Collyrie or *eye-ſalve there is,which ta-
B keth the name alſo of Saffron. And when the ointment made of Saffron called Crocinium, is ſtrained and preſſed out,the grounds which remaine is named Crocomagma, which alſo is not without ſome eſpeciall uſes,for it cureth the ſuffuſion of the eyes, or the cataract: but it cauſeth ordeur and heat of urine more than Saffron it ſelfe.The beſt is that accounted,which if a man taſt in his mouth,doth colour his ſpittle and ſtaine his teeth.

* Nay it is a great enemie unto it.

* *Dia-crocu. Paul. Ægin.*

As touching the Flower-de-lis, the red is thought to bee better than the white. Certes if little infants doe weare it tied about them by way of necklace,collar,or girdle,it is ſuppoſed to be a
F ſingular remedie,eſpecially when they breed teeth or have the chincough.Alſo if they bee troubled with the *worms,they hold it good gently to inſtill the ſame into the body[either by drink or clyſters.]All other operations that the Flower-de-lis hath, differ not much in effect from honey.
C A ſingular propertie it hath to cleanſe the head from ſores and ſkals, and generally to mundifie all old impoſtumate ulcers. Two drams therof taken with honey,eaſeth the bellie,and provoketh to the ſtoole.Given in ordinarie drinke,it ſtaieth the cough,appeaſeth wrings,and diſſolveth ventoſities in the bellie.In vinegre it openeth the opilations of the ſpleen.And being taken with water and vinegre together, it is an effectuall remedie againſt the ſtinging of ſerpents and ſpiders. The weight of two drams eaten with bread or drunke in water, reſiſteth the poyſon of ſcorpions. Being made into a liniment with oile,and ſo applied,it cureth the bitings of mad dogs, & heateth the parts mortified with extreame cold.In the ſame manner alſo it allaieth the pains of the ſinewes.Reduced into an ointment with Roſin,it is ſingular for the paine of the loins & the gout Sciatica.This root is hote in operation.If it be drawne or ſnuffed up into the noſe,it cauſeth ſneeſing,and purgeth the head.A liniment of it & Pome-quinces or Peare-quinces,eaſeth the head-
D ach: it repreſſeth alſo the vapours flying up into the head, cauſing diſtemperature of the brain,
F in a ſurfeit of wine or ſtrong drinke. It helpeth ſtreightneſſe of breath, and ſuch as cannot take their wind but ſitting upright.It provoketh vomit,if it be taken to the weight of two Oboli.A cataplaſme of it & honey together,draweth forth ſpils of broken bones.The pouder of it is much uſed for Whit-flawes: and the ſame applied with wine, taketh away corns and werts: but it muſt lie on three daies before you unbind and take it from the place. The very chewing of it, correcteth a ſtrong and ſtinking breath: as alſo the filthie ſavour of the arme-holes. The juice thereof doth mollifie all hard tumors. It provoketh ſleepe, but it conſumeth ſperme or naturall ſeed. The Fiſſures in the ſeat, as alſo the blind and ſwelling piles in the fundament and all ſuperfluous
E excreſſences of the bodie,it cureth.

* *Tinearum vitio. Plinie* commonly taketh *Tineas* for wormes in the belly: although otherwiſe it betokeneth ſores and ſkals in the head.

There is a wild kind of Floure-de-lis,which ſome call Xyris: the root of this hearb is good to reſolve and diſcuſſe the ſwelling kernels named the Kings evill, hot biles,and riſings in the groin. Howbeit for to worke theſe effects,there be certaine ceremonies preciſely to be obſerved,namely,That it be taken out of the ground with the left hand in any caſe. *Item*, that they who gather it doe ſay in the gathering,For whoſe ſake they pluck it up; and withall,name the perſon.And here in making mention of this matter,I cannot but detect the knaverie of theſe Herbariſts and Simplers: Their maner is not to employ and occupie all that they have gathered,but reſerve & keepe part thereof,as alſo of ſome other hearbs,as namely of Plantaine: and if they bee not well contented,nor thinke themſelves paied throughly for their paines in the cure, they make no more
F adoe but burie and cover within the earth that part which they kept by them, in the ſame place where it was digged forth. And I beleeve verely they have an unhappie meaning and a certaine kind of witchcraft herein: forſooth,That the maladies which they ſeemed to have healed,ſhould breake out and be ſore againe,to the end that they might be ſet on work anew. As touching Saliunca,the decoction of it in wine and ſo taken,ſtaieth vomits,and doth corroborat the ſtomack.

Muſæus

Muſæus and *Heſiodus* the Poets have a great opinion of Polium: for they give counſell to all G
thoſe that would come to preferment & promotion, for to be annointed all over with a liniment thereof: ſuch alſo as be deſirous of renowme and glorie, to be ever handeling of it, to ſet it alſo, and maintaine it in their gardens. True it is, that folke doe carie Polium about them ordinarily, or lay it under their beds for to chaſe away ſerpents. Phyſicians doe ſeeth it either new and green, or drie, in wine, and thereof make a liniment: or els they give it to drink in vinegre, to thoſe that be pained with the jaundiſe; yea, and to ſuch as be newly fallen into the dropſie, they give counſell to drinke the decoction thereof, being ſodden in wine. And of it ſo prepared, they make a liniment for to be applied unto greene wounds. Moreover, this hearbe is very good to ſend out the after-burden in women newly brought to bed, and to expell the dead infant out of the mothers wombe. And otherwiſe it ſerveth very well to mitigate any paines of the bodie. It doth purge and H
evacuat the bladder: and in a liniment applied to the eyes, reſtraineth their exceſſive watering. I know not any other hearbe better to goe with other ingredients into antidots or counterpoyſons (named of the Greekes Alexipharmaca) than this. Howbeit, ſome denie all this, and are of opinion that it is hurtfull to the ſtomacke, that the drinking of it ſtuffeth the head, and cauſeth women to fall into labour before their time. They ſay alſo, that this ceremonie would be precisely obſerved, That in the very place where this plant is found, ſo ſoone as ever it is gathered it ſhould be hanged preſently about the neck of the partie, with a ſpeciall care that it touch not the ground firſt, and then is it an excellent remedie for the cataract in the eye. And theſe authours deſcribe this hearbe to have leaves like to Thyme, but that they bee ſofter and covered over with a more hoarie and woollie downe. Being taken with wild Rue in raine water, ſo that it bee beaten before I
into pouder, it doth mitigat (by report) the deadly paines cauſed by the ſting of the Aſpis, it bindeth and draweth up a wound, it keepeth corroſive ſores from feſtering and going farther, as well as the flowers of the Pomegranat.

As namely *Dioſcorides.*

The hearb Holochryſos if it be taken in wine, helpeth the ſtrangurie, and ſuch as cannot piſſe but by drops. And a liniment thereof is paſſing good to repreſſe the flux of humors to the eies. If it bee incorporat with Tartar or wine lees burnt into aſhes, and drie Barley groats; it mundifieth the skin, and riddeth away ring-wormes, tettars, and ſuch like wild fires.

As for Chryſocome, the root of it is hote, and yet aſtringent. It is given to drinke for the diſeaſes of the liver and the lights. And being ſodden in honied water, it aſſuageth the paines incident to the matrice. It provoketh womens monthly purgation: and being given in drink raw, K
it purgeth waterie humors gathered in the dropſie.

Touching Baulme, which the Greekes call Melittis or Meliſſophyllon: if Bee-hives be rubbed all over and beſmeared with the juice thereof, the Bees will never away; for there is not a flower whereof they bee more deſirous and faine, than of it: and in truth, looke in what garden there groweth abundance of this hearbe, the Bees there when they ſwarme, will bee ſoone intreated to tarie, and not be haſtie to wander far abroad. The ſame is a moſt preſent remedy not only againſt their ſtings, but alſo of weſpes, ſpiders, and ſcorpions. And being tempered with a little nitre, it is ſingular againſt the *ſtrangulation of the mother. Taken it wine, it pacifieth the wrings and torments of the bellie. The leaves thereof being ſodden with ſalt, and brought into an ointment, are ſingular good for to be applied unto the ſcrophules or ſwelling kernils called the Kings evill: and L
likewiſe to the accidents of the ſeat and fundament, as the ſwelling hæmorrhoids or piles. The juice taken in drink, bringeth women to their ordinary monthly courſes: it diſcuſſeth ventoſities, and healeth ulcers: it allaieth the paines of any gouts, and cureth the biting of mad dogs: it is good for the bloudie flix that hath run on a long time: as alſo thoſe fluxes which proceed from the imbecillitie of the ſtomacke: it helpeth them that bee ſtreight in the cheſt, and cannot take their wind but bolt upright: it mundifieth alſo the ulcers within the breaſt. To conclude, it is ſaid to be a ſingular remedie & none like unto it, for to diſpatch the webs in the eye, if they be annointed with the juice thereof and honey tempered together.

* *Dioſcorides* hath μυκήτων, *i.* Muſhromes: whereof there be ſome that be daungerous for ſuffocation. But *Plinie* as it ſhould ſeeme, read it μητρῶν, and accordingly hath tranſlated it.

Melilote alſo is thought to be good for the eyes, if it bee applied with milke or line ſeed. It aſſuageth alſo the paine of the jawes and head, if it be laid too with oile of Roſes: likewiſe it dooth M
mitigat the paine in the eares, if it be inſtilled or dropped into them with wine cuit. Moreover, the tumors and breaking out of the hands it helpeth. Being boiled in wine, or ſtamped greene, it eaſeth the greeſe of the ſtomacke. The ſame effect it hath in the paine of the matrice. But if the cods be amiſſe, if the Longaon or tuill be fallen, and beare out of the bodie; or if that part bee

affected

affected with other accidents, Bath the place with a decoction of it, boiled green in water or cuit, and the patient ſhall find eaſe. But if there bee an ointment made of it and oile of Roſes incorporat together, it is a ſoveraigne remedie for all cancerous ſores. If it be boiled firſt in ſweet wine or cuit, it is the better for the purpoſe aforeſaid: and ſo prepared, a ſpeciall and effectuall thing it is for the wens called Melicerides, wherein is engendred matter reſembling honey.

Chap. xxi.

Of Trefoile, and Thyme: of the day Lillie Hemerocalles: of Elecampane, and Sothernewood, and Cypres.

I Am not ignorant, that folke are verely perſuaded, how that Trefoile or three leaved graſſe, is of great force againſt the ſtings of ſerpents and ſcorpions, if either twentie grains of the ſeed bee taken inwardly in wine, or water and vinegre together; or if the leaves and the whole hearbe be ſodden, and the decoction drunke: as alſo, that ſerpents are never ſeen to lie under this Trefoile. Moreover, I know full well that diverſe Authors renowmed and of great credit, have delivered in their bookes, That five and twentie grains of that Trefoile, which wee called Menianthes, is ſufficient for a preſervative and antidote againſt all poyſons whatſoever: beſides many other medicinable vertues which bee aſcribed to this hearbe. But for mine owne part, I am induced by the authoritie of the moſt grave and reverend Poet *Sophocles*, to ſtand againſt their opinion: for he affirmeth plainely, That Trefoile is venomous. Likewiſe, *Simus* the Phyſician dooth report, That if the decoction of it ſodden, or the juice thereof ſtamped, bee poured or dropped upon any part of the bodie which is ſound, it will cauſe the ſame fierie and burning ſmart as followeth upon a place bitten or ſtung with a ſerpent. And therefore I would thinke with them, and give counſell alſo, that it is not to be uſed otherwiſe than a countrepoyſon. For it may be peradventure, that in this as in many other, one poyſon (by a certaine antipathie & contrarietie in nature) expelleth and mortifieth another. Moreover, this I mark and obſerve in their writings, That the ſeed of the Trefoile which hath ſmalleſt leaves, if it bee reduced into a liniment, is ſingular good to embelliſh womens skin, and to preſerve their beautie, if the face be annointed therwith.

Thyme ought to be gathered whiles it is in the flower, and then to be dried in the ſhade. Now there are of Thyme two kinds, to wit, the white; which hath a woodie root, growing upon little hils; and this is thought to be the better: the ſecond, is blacker, & carieth beſides a black flower. They are thought both of them, the one as well as the other, very good to cleare the eyeſight, whether they be eaten with meats or taken as a medicine. In like maner, an electuarie or lohoch made of Thyme, is ſuppoſed to be excellent good for an old cough: and being taken with hony and ſalt, to raiſe and breake fleame, cauſing the ſame to be raught up with more facilitie. Alſo that if it bee incorporat with honey, it will not ſuffer the bloud to clutter and congeale within the bodie. Applied outwardly as a liniment with Senvie, it dooth extenuat and ſubtiliat the rhewme that hath of long time fallen into the throat and wind pipe: and ſo likewiſe it amendeth the greevance of ſtomacke and bellie. Howbeit, theſe Thymes muſt bee uſed with meaſure and moderation: becauſe they ſet the bodie into an heat, although they be binding & make the belly coſtive. Now in caſe there be an exulceration in the guts, there muſt be taken the weight of one denier or dram in Thyme, to every ſextar of honey and vinegre: ſemblably, it muſt bee ordered in caſe of the pleuriſie; and when there lieth a paine betweene the ſhoulders or in the breaſt. A drink made of Thyme with honey and vinegre in manner of a juleb or ſyrrup, cureth the greefe of the midriffe and precordiall parts neare unto the heart. And verely a ſoveraigne potion this is to bee given unto them that bee troubled in mind and lunaticke, as alſo to melancholicke perſons. The ſame alſo may bee given to thoſe who bee ſubject to the epilepſie or falling ſickneſſe: whom the very perfume and ſmell of Thyme will raiſe out of a fit, and fetch them againe, when the diſeaſe is upon them: It is ſaid, that ſuch ſhould lie ordinarily in a ſoft bed of Thyme. This hearbe is proper for thoſe that cannot draw their breath unleſſe they ſit upright, and to ſuch as are ſhort winded, yea, and good for women, whoſe monthly courſes are either ſuppreſſed or come but ſlowly. And ſay that the infant were dead in the wombe, a decoction of Thyme, ſodden in water unto the thirds & ſo taken, doth ſend it forth of the bodie. Men alſo do find a great benefit by Thyme, if they drinke a ſyrrup made of it with honey and vinegre, in caſe of ventoſities and inflations: alſo, if their bellies be ſwolne or their cods; yea, and when their bladder is pained. Moreover, if it

be

be applied as a cataplasme with wine, it assuageth all tumors, and bringeth downe swellings: it G
staieth also the impetuous and violent flux of any humours to a place, readie to breed an impostumation. But if the same be applied with vinegre, it taketh away werts and hard callosities. It is good for the Sciatica and other gouts, for dislocations and lims out of joint, being beaten unto pouder, and bestrewed upon a quilt of wooll, moistned and bathed with oile, and so laid unto the place in manner of a fomentation. A potion also thereof is usually given in case of the Gout, to wit, the weight of three Obols, in as many cyaths of vinegre and honey. Also when the stomack riseth against meat and refuseth it, a drage or pouder of it with salt, bringeth the appetite again.

The day Lillie Hemerocalles, hath leaves of a pale and wanniſh greene colour, otherwise soft and gentle: the root is bulbous or Onion like, and odoriferous: which if it bee laid to the bellie in manner of a cataplasme, doth evacuat waterie humors, yea, and thicke bloud that lieth cluttered within the bodie readie to do a mischeefe. The leaves make an excellent liniment to annoint the eyes and the parts about it, as a defensative against the rheume falling thither with violence; as also to be applied unto the paps and breasts of women, which ake and are pained presently after child-birth. H

Helenium, an hearbe which sprang first from the teares of ladie *Helena*, as I have alreadie shewed, is thought to have a speciall vertue to preserve beautie, and to maintaine the skin fair, pure, and delicat, as well in the face of women, as in other parts of their bodie. Moreover, a deep opinion there is of this hearbe, that whosoever use it shall proove amiable and gracious: they shall I say, win love and favour whersoever they come. Also there is attributed and prescribed to this hearbe, if it be taken in wine, a mightie operation to procure mirth and make the heart merie: and it is thought to be as effectuall that way, as was that noble drinke Nepenthes (so highly commended in *Homer*) so called, for that it puts away all heavinesse, sorrow, and melancholie. And in faith the juice of Helenium is *passing sweet and pleasant. The root of Helenium taken in water upon an emptie stomacke when a man is fasting, is very good for them that are streight winded, & cannot take their breath but upright. Now is this root white within and *sweet also as is the hearbe. The same is given to drinke in wine against the sting of serpents. To conclude, being beaten into pouder, it is said for to kill Mice. I

As touching Abrotonum, I find that there be two kinds of it. The one of the plaines, which I take to be the male; the other of the mountaines, which I would have to goe for the female. Neither of them both there is, but it is as bitter as Wormewood. The best is that which groweth in Sicilie: next to which, that of Galatia is most esteemed. The leaves are much used, but the seed much more, for to heat and chause any part of the bodie. And therefore it is good and comfortable for the sinews: it cureth the cough: it procureth them libertie of breath, who cannot fetch their wind lying or leaning with their heads: it helpeth the crampe: it doth consolidat ruptures: it easeth the pain of the loines, and maketh free passage for urine. The right manner of the decoction as well of the one as the other, is to seeth them in bunches or bundles like handfuls, untill a third part of the water bee consumed; and foure cyaths is an ordinarie draught of this decoction. The seed also being beaten into pouder, is given to the weight of a dram in water, for a drink. And indeed so taken, it comforteth the matrice and the naturall parts of women. A poultesse made of it and Barley meale, applied unto dull and broad swellings which gather not quickly to an head, doth ripen them apace and bring them to suppuration. Also being reduced into a liniment with a quince rosted or baked, it cureth the inflamination of the eyes, if they be annointed therwith; it hath a vertue to drive away serpents; and in case one bee stung with them alreadie, it expelleth the poyson, taken inwardly in drinke; or laid too outwardly in forme of an ointment, draweth it forth. But most effectually is the power thereof seene, in those poysoned and venomous stings which cause the bodie to shake, chill, and quake for cold; as namely, those of scorpions, & the spiders called Phalangia. Moreover, good it is also for other poysons, if it be taken in drinke: and so it helpeth those that bee surprised with any extreame cold howsoever. This propertie likewise it hath, to draw forth of the bodie all spils or any thing els that sticketh within the same. It driveth out of the bodie the wormes engendred in the guts. Finally, it is said, that if a braunch thereof be laid under the pillow where folke lieth in bed, it will put them in mind of wantonnesse, and provoke them to lust: and against all charmes, enchantments, & witchcrafts, which coole the heat of the flesh, and disable or bind any person from the act of generation, it is the most powerfull heath of all others. K L M

*So is not *Inula*, or our Elecampane. And therfore either it is not Helenium here: or els *Plinie* doth mistake in this place, as in many others.

*which agreeth not with ours.

CHAP.

A

Chap. xxii.

The medicinable vertues of Leucanthemum, and Sampſuchum, [i. Marjerom.]

LEucanthemum mingled with two parts of vinegre, and ſo given to drinke, is good for thoſe that be ſhort winded. As for Sampſuchum or Amacacum, that of Cyprus is moſt commended, and the ſweeteſt of all other: this heatb brought into a liniment, and applied with vinegre and ſalt, is good againſt the venome of Scorpions. Moreover, if it be put up into the naturall parts of a woman in forme of a peſſaine, it helpeth much to bring downe their monethly courſes: for if it be taken in drinke, it is not ſo effectuall. Applied as a liniment, after it is incor-
B porat with barley groats, it reſtraineth the flux of humors to the eyes. The juice thereof when it is ſodden, diſcuſſeth and diſſolveth the ventoſities that moove pangs and wrings in the belly. A good medicine it is to provoke urine, and by conſequence, for thoſe that be in a dropſie. Marjoram dried, mooveth ſneezing. Thereof is made an artificiall oile, called Sampſuchinum or Amaracinum, ſingular for to heat the ſinewes, and to mollifie their ſtiffeneſſe and hardneſſe: as alſo by the heat thereof to comfort the matrice. The leaves applied with honey, ſerve very well to reduce the blacke and blew marks occaſioned by ſtripes or bruiſes, to their naturall and lively colour: and brought into a cerot with wax, it is good for diſlocations of joynts.

Chap. xxiii.

C

The vertues and properties of Anemone or Windfloure, requiſit in Phyſicke.

WEe have diſcourſed of Anemone and thoſe kinds thereof, which go to the making of chaplets and garlands: it remaineth now therefore to ſpeake of thoſe which ſerve for good uſe in Phyſicke. But firſt as touching Anemone in generall: ſome there be who call it Phenion; and two principall kinds there be of it: The firſt groweth wild in the woods: the ſecond commeth in places well tilled and in gardens; but both the one and the other love ſandie grounds. As for this later kind, it is ſubdivided into many ſpeciall ſorts: for ſome have a deepe red ſcarlet floure; and indeed ſuch are found in greateſt plentie: others beare a purple floure: and there be againe which are white. The leaves of all theſe three be like unto Parſley. None of them
D ordinarily grow in heigth above halfe a foot; and in the head of their ſtemme, they ſhoot forth ſprouts in manner of the tendrils of Aſparagus. The floure hath this propertie, Never to open but when the wind doth blow; whereupon it tooke the name * Anemone in Greeke. But the wild Anemone is greater and taller: the leaves alſo are larger; and the flours are of a red colour. Many writers, beeing carried away with an error, thinke this Anemone and Argemone to be both one: others confound it with that wild Poppie which we named Rhœas: but there is a great difference betweene them, for that both theſe hearbs doe floure after Anemone: neither doe the Anemonæ yeeld the like juice from them, as doth either Argemone or Rhœas before-named: they have not alſo ſuch cups and heads in the top, but onely a certaine muſculoſitie at the ends and tips of their braunches, much like to the tender buds of Aſparagus.

Hereupon Anemone is called Role-parſley.

* ἀνεμὸς in Greeke, betokeneth Wind: whereupon *Ruellius* called it *Herba-venti:* and *Gerard*, Wind-floure more properly.

E All the ſorts of Anemone or Wind-floure, bee good for the head-ach and inflammations thereof; comfortable to the matrice of women, and encreaſeth their milke. Being taken inwardly in a Ptiſane or barley gruell, or applied outwardly as a cataplaſme with wooll, this hearbe provoketh their monthly tearms. The root chewed in the mouth, purgeth the head of fleame, and cureth the infirmities of the teeth. The ſame being ſodden, and laid to the eyes as a cataplaſme, repreſſeth the vehement flux of waterie humours thither. The Magicians and Wiſe men, attribute much to theſe hearbs, and tell many wonders of them; namely, That a man ſhould gather the firſt that he ſeeth in any yeere, and in the gathering to ſay theſe words, *I gather thee for a remedie againſt tertian and quartan agues:* which done, the partie muſt lap and bind faſt in a red cloth the ſaid floure, and ſo keepe it in a ſhadie place; and when need requireth, to take the ſame,
F and either hang it about the necke, or tie it to the arme or ſome other place. The root of that Anemone which beareth the red floure, if it be bruiſed and laid upon any living creature whatſoever, raiſeth a bliſter, by that cauſticke and corroſive vertue which it hath: and therefore it is uſed to mundifie and cleanſe filthie ulcers.

Chap. xxiiii.

The vertues of Oenanthe in Physicke.

OEnanthe is an hearb growing upon rockie and ſtonie grounds. The leaſe reſembleth thoſe of the Parſnep: roots it hath many, and thoſe big. The ſtem and leaves of this hearbe, if they be taken inwardly with honey and thicke ſweet wine, doe cauſe women in labour to have eaſie deliverance, and withall, do cleanſe them well of the after-birth. Eaten in an electuarie, or licked in a lohoch made with honey, the ſaid leaves doe rid away the cough, and provoke urine. To conclude, the root alſo is ſingular for the infirmities and diſeaſes of the bladder.

Chap. xxv.

The medecines made with the hearb Heliochryſon.

HEliochryſon, which others name Chryſanthemon, putteth footh little braunches verie faire and white: the leaves are whitiſh too, much like unto Abrotomum: From the tips and ends of which braunches, there hang downe certaine buttons (as it were) like berries round in a circle, which with the repercuſſion and reverberation of the Sun-beames, doe ſhine againe like reſplendent gold. Theſe tufts or buttons, do never fade nor wither: which is the cauſe that the chaplets wherewith they crowne and adorne the heads of the gods, be made thereof: a ceremonie that *Ptolomæus* K. of Ægypt obſerved moſt preciſely. This hearbe groweth in rough places among buſhes and ſhrubs. If it be taken in wine, it provoketh urine, and womens fleures. All hard tumors and inflammations it doth diſcuſſe and reſolve without ſuppuration. A liniment made with it & honey, is good to be applied unto any place burnt or ſcalded. It is given in drinke uſually for the ſting of ſerpents: for the paines and infirmities alſo of the loines. If it be drunke in honyed wine, it diſſolveth and conſumeth the cluttered bloud, either in the belly and guts, or the bladder. The leaves taken to the weight of three Oboli in white wine, doe ſtay the immoderat flux of the whites in women. This hearbe, if it be laid in wardrobes, keepeth apparell ſweet, for it is of a pleaſant odour.

Chap. xxvi.

The vertues and properties of the Hyacinth, and Lychnis, in Phyſicke.

THe Hyacinth loveth Fraunce very well, and proſpereth there exceedingly. The French uſe therewith to die their light reds or luſtie-gallant, for default of graine to colour their ſcarlet. The root is bulbous and onion-like, well knowne to theſe ſlave-courſers, who buy them at beſt hand; and after, tricking, trimming, and pampering them up for ſale, make gain of them: for being reduced into a liniment, they uſe it with wine to annoint as well the ſhare of youths, as the chin and cheeks; to keepe them for ever being under-growne, or having haire on their face, that they may appeare young ſtill and ſmooth. It is a good defenſative againſt the pricke of venomous ſpiders; and beſides, allaieth the griping torments of the belly. It forcibly provoketh urine. The ſeed of this hearbe given with * Abrotonum, is a preſervative againſt the venome of ſerpents and ſcorpions; and cureth the jaundiſe.

*ὑπὸ in *Dioſcorides*, it ſeemeth he read ἀβροτόνῳ.

As touching Lychnis, that flaming-hearbe ſurnamed Flammea, the ſeed of it beaten into powder and taken in wine, is ſingular good againſt the ſting of ſerpents, ſcorpions, hornets, and ſuch like. The wild of this kind is hurtfull to the ſtomacke, and yet it is laxative and purgeth downward. Two drams thereof is a ſufficient doſe to purge choller, for it worketh mightily. Such an enemie it is to ſcorpions, that if they doe but ſee it, they are taken with a nummedneſſe that they cannot ſtir. In Aſia or Natolia, they call the root of this hearbe Bolites, which if it be laid upon the eyes and kept bound thereto, taketh away the pin and the web, as they ſay.

Chap. xxvii.

The medicinable vertues of Pervincle, Ruſcus, Batis, and Acinos.

ALſo the Pervincle, called by the Greeks *Chamædaphne, if it be ſtamped drie into powder, and a ſpoonfull thereof given in water to thoſe that are full of the dropſie, it doth evacuat moſt ſpeedily, the waterie humors collected in their belly, or otherwiſe. The ſame root roſted

* or rather, *Daphnoides*, out of *Dioſcor.*

A roſted in embres, and well ſprinkled and wet with wine, diſcuſſeth and drieth up all tumors, being applied thereto. The juice thereof dropped into the eares, cureth their infirmities. A cataplaſme of it applied to the belly, helpeth them (as they ſay) very much, who are vexed either with gripes or fluxes of the wombe.

Concerning Ruſcus, the decoction of the root, if it bee given in drinke each other day, to them that be tormented either with the ſtone, or the wringing pains of the ſtrangurie, or to ſuch as piſſe bloud, it helpeth them. Now the preparing of this medecine, and the proportion alſo of it, is in this wiſe: The ſaid root muſt be taken out of the ground, as it mought be to day, and to morrow morning betimes it would be ſodden: and a ſextar of this decoction is to bee mingled with two cyaths of wine, and ſo the Patient is to drinke it. Some make no ſuch adoe, but take the
B root while it is green, ſtamp it, & in water draw the juice raw as it is, & ſo drinke it. In ſum, it is held for certein, That there is no better thing in the world for the infirmities and diſeaſes incident to the privie members of men, than to bruiſe the tender crops of this hearbe, and then with wine and vinegre to preſſe out the juice, and afterwards to drinke the ſame. In like manner, *Batis is good for them that be bound and coſtive in the belly: and a liniment of it, after it is roſted in the embres and ſtamped, is ſingular for the gout. Laſt of all, as touching the hearb Acinos, the Ægyptians uſe to ſow it, as well to make guirlands thereof, as to eat it. Surely, I would ſay it were Baſill, but that the braunches and leaves be more hairie; for certeinly it is very odoriferous. It hath a propertie to provoke urine, and womens fleures.

* Taken by the moſt part, for wild Baſill.

C

Chap. xxviii.

The medicines that Colocaſia or the Ægyptian Beane doth affourd.

G*Laucias* was of opinion, That Colocaſia was good to lenifie or mitigat the acrimonie of humors within the bodie; and withall, to helpe the ſtomacke.

Chap. xxix.

The medicines made of Anthalium.

D TOuching Anthalium (whereof the Ægyptians uſe much to eat) I find no other uſe of it, but onely from the kitchin to the table. Indeed there is an hearb much like to it in name, which ſome call * Anthyllion, others Anticellion: whereof bee two kinds; The one hath leaves and braunches like to the Lentill, and groweth a hand-breadth or ſpan high: it commeth up in * ſandie grounds expoſed to the Sun, and is ſaltiſh in taſt. The other reſembleth * Chamæpitys, but that it is lower and more hairie: it beareth a purple floure, carrieth a ſtrong ſent, and loveth to grow in ſtonie places. The former kind is a moſt convenient and proper hearb for the diſeaſes of the matrice and the naturall parts of women. Alſo being applied as a cataplaſme with oyle roſat and milke, it is a vmbretarie medicine. In caſe of the ſtrangurie and pains of the kidnies, it is given with good ſucceſſe to the quantitie of three drams. The other likewiſe is given to drink the weight of foure drams with honey and vinegre, for to mollifie the hardneſſe of the matrice, to
E aſſuage the torments of the belly, and to cure thoſe that be taken with the falling ſickneſſe.

* Some take it for *Kali*.
* ὑφυμέγεις, *Dioſcor.* ſomewhat brackiſh.
* *Iva muſcata*, or *Arthritica*.

Chap. xxx.

*Of * Parthenium, and the medicinable vertues that it hath.*

AS for Parthenium, ſome name it Leucanthe, others Tamnaum; but our countreyman *Celſus* the Phyſician, calleth it Perdicium and Muralium. It groweth in the mounds and hedges about gardens: it bringeth forth a white floure, ſavouring like an * apple, and having a bitter taſt. The decoction of this hearbe, if a woman ſit over it and receive the fume into her bodie, is good to mollifie the hard tumors of the matrice and naturall parts; as alſo to diſ-
F cuſſe all inflammations. A powder made of this hearbe dried, and incorporat with honey and vinegre, [*i.* Oxymell] and ſo applied, purgeth choller aduſt, and melancholy. In which regard, it is good for the ſwimming and dizzineſſe of the braine, and thoſe that are given to breed the ſtone. Being uſed in manner of a liniment, it is good for the ſhingles and S. *Anthonies* fire: likewiſe for the kings evill if it be incorporat with old ſwines greaſe. The Magicians uſe it much for

* Some thinke it is Mother-wort, others Feverfew.
* Surely according to *Dioſcorides*, *Plinie* ſhould have written thus: *Flore per ambitum candido, in. tus melino; id eſt*, with a floure white round about, but within of a darke yellow like to honey: & this agreeth to Feverfew.

tertian agues: but they lay a great charge, that it ſhould in any wiſe be plucked up with the left hand, and the parties preciſely named for whoſe ſake they gather it: but in any caſe they who plucke it, muſt not looke behind them: which done, a leafe of the hearbe muſt be put under the tongue of the ſick Patient; and when it hath been held ſo a little while, it muſt anon be ſwallowed downe in a cyath of water. G

Chap. xxxi.

Of Nightſhade or Morell: of Alkakengi and Halicacabus, and their uſe in Phyſicke.

NOw concerning Nightſhade or Morell, which ſome name Strychnos, others have written by the name of Trychnos: would to God that the guirland-makers of Ægypt had not emploied and uſed in their chaplets the flours of two kinds of them, induced thereto by the reſemblance that they have to the Ivie flours: of which, the ſecond that hath red berries like cherries of a ſcarlet colour, conteined within certaine bladders, and thoſe berries full of grains or ſeeds, ſome name * Halicacabus, others Callion; but our countreymen here in Italy call it *Veſicaria, becauſe it is good for the ſtone in the bladder. Certes, this plant is more like a ſhrub or little tree full of braunches, than any hearbe: bearing great and large bladders, and thoſe faſhioned like a top, broad & flat at one end, and ſharpe pointed at another; encloſing within it a great berie, which ripeneth in the month November. The third kind of Strychnos or Solanum, hath leaves like to Baſill: but I muſt but lightly touch this hearbe, and not ſtand long about the deſcription either of it or the properties which it hath; ſince my purpoſe is to treat of holeſome remedies to ſave folke, and not of deadly poiſons to kill them: for certes, this hearbe is ſo dangerous, that a very little of the juice thereof is enough to trouble a mans braine, and put him beſides his right wits. And yet the Greeke writers have made good ſport with this hearbe, and reported pretie jeaſts of it: For (ſay they) whoſoever taketh a dram of the juice, ſhall have many ſtraunge fantaſies appearing evidently unto them in their dreams; if they be men, that they dally with faire women; if women, that they be wantons playing and toying with men, without all ſhame and modeſtie; and a thouſand ſuch vaine illuſions: but in caſe they take this doſe double, then they ſhall proove fooliſh indeed, broad waking, yea and goe beſides themſelves: let them take never ſo little more, it is mortall, and no remedie then but death. This is that poiſon, which the moſt harmeleſſe and beſt minded writers that ever wrote, called ſimply Dorycnion: for that ſouldiers going to battaile, uſed to annoint and envenome therewith the heads of their arrows, darts, and ſpeares, growing as it did ſo commonly in every place. But other writers, who had not ſought ſo far into the matter, nor adviſedly conſidered of it, gave it the name of Manicon. But thoſe that of a naughtie mind, cared not ſecretly to empoiſon the whole world, have hidden the daunger thereof, and tearme it by a name pretending no harme; ſome calling it Neuris, others Periſſon. But as I proteſted before, I thinke it not good to be too curious and buſie about the deſcription of this hearbe, notwithſtanding I might ſeeme to give a good caveat of it, by further particularizing thereof. Well, the very ſecond kind which they call Halicacabus, is bad enough, for it is more ſoporiferous than Opium, and ſooner caſteth a man into a dead ſleepe, that he ſhall never riſe againe. Some name it Morion, others Moly: and yet it hath not wanted thoſe that have thought it praiſe-worthie: for *Diocles* and *Euenor* have highly commended it: and *Timariſtus* verely hath not ſtucke to write verſes in the commendation of it: A wonderfull thing, that men ſhould ſo farre over-paſſe themſelves, and forget all honeſtie and plaine dealing: for they ſay (forſooth) that a collution made of this hearbe, confirmeth the teeth that be looſe in the head, if the mouth be waſhed therewith. And one onely fault they found in Halicacabus, (otherwiſe it might be praiſed without exception) that if the ſaid collution were long continued, it would trouble the brain, and bring the partie that uſed it, to foolerie and idleneſſe of head. But for mine owne part, my meaning is not to ſet downe any ſuch receits and remedies, which may bring a further daunger with them, than the very diſeaſe it ſelfe for which they are deviſed. The third kind alſo is commended for to be eaten as meat, although the garden Morell is preferred before it in pleaſantneſſe of taſt. Moreover, *Xenocrates* avoucheth, That there is no maladie incident to our bodie, but the ſaid Morell is good for it. Howbeit, I make not ſo great reckoning and account of all the helps that theſe and ſuch like hearbs may affourd, as I do make conſcience H I K L M

to

* *Alkakengi*, or Winter-chery. * or rather for that the ſaid berrie lyeth within a cod like a bladder.

A to deliver them in writing, especially seeing wee have so great store of safe and harmelesse medecines, which we may be sure can doe no hurt. Indeed, the root of Halicacabus they use to drinke and make no bones at it, who would be knowne for great prophets to foretell future things: and therefore it is alone for them, to be seene furious and raging, the better to colour their knaverie and lead the world by the nose in a superstitious conceit and persuasion of their divine gift of prophesie, and so to feed men still in their folly. But what is the remedie, when a man is thus overtaken? (for surely I am better content to deliver that) Even to give the partie thus intoxicat, a great quantitie of mead or honeyed water, and to cause him to drinke it off as hot as he can. Neither will I over-passe this one thing besides, That Halicacabus is so adverse unto the nature of the Aspis; that if the root thereof be held any thing neare unto the said serpent, it will bring
B asleepe and mortifie that venomous creature, which by a soporiferous power that it also hath of the owne, casteth a man into a deadly sleepe, and killeth him therewith. And therefore, to conclude, hereupon it commeth, that the same root bruised and applied with oile, is a soveraigne and present remedie to them who are stung by the foresaid Aspis.

Chap. xxxii.

Of *Corchorum*, and *Cnicus*.

THey of Alexandria in Ægypt use to eat ordinarily of Corchorum: This herb hath leaves enwrapped and enfolded one within another, after the manner of the Mulberrie. Good it
C is (as they say) for the midriffe and the parts about the heart: also to recover haire that is falne away by some infirmitie; and likewise for the red pimples or sauce-fleame in the face. I read moreover, that the skab or mange in kine and oxen, is most speedily cured thereby. And *Nicander* verely doth report, That it helpeth the stinging of serpents, if it bee used before it be in the floure. As touching Cnicus, otherwise called Atractylis (an hearb appropriat to the land of Ægypt) I would thinke it meet not to use many words about it, but that it yeeldeth a soveraigne remedie against the poison of venomous beasts; yea and the daungerous mushroms, if a man have eaten them. This is certain, and an approoved experiment, That whosoever are wounded by the sting of scorpions, shall never feele smart or paine, so long as they hold that herb in their hand.

D

Chap. xxxiii.

Of Persoluta.

THe chaplet-makers in Ægypt set great store by Persoluta also, which they sow and plant in their gardens, only for to make coronets and guirlands. Two kinds there be of it: the male and the female. It is said, that the one as well as the other, if it be put under man or woman in bed, they shall have no mind nor power at all to play at *Venus* game, and specially the man.

Chap. xxxiiii.

Of Measures and Weights.

E

ANd forasmuch as we shall have occasion oftentimes in setting downe Weights and Measures, to use Greeke vocables, I care not much even in this place, to interpret those words once for all. First and foremost, the Atticke Drachma [for all Physicians in manner goe by the poise of Athens] doth peise just a Romane silver denier: and the same weigheth also six Oboli: now one Obulus is as much in weight as ten Chalci. A Cyathus, of it selfe alone, commeth to ten drams in weight. When you shall read the measure of Acetabulum, take it for the fourth part of Hemina, that is to say, fifteen drams. To conclude, Mna, which we in Latine call Mina, amounteth just to an hundred drams Atticke.

F

THE XXII. BOOKE OF THE HISTORIE OF NATVRE,

WRITTEN BY C. PLINIVS SECVNDVS.

The Proëme.

A Man would thinke, who did but read the former booke, that dame Nature and the Earth both, had done their parts and shewed their wonderfull perfection sufficiently: if he considered withall the admirable vertues of so many hearbs which they have brought forth and bestowed upon mankind, as well for pleasure as profit. But see what a deale of riches more is yet behind; and how the same as it is harder to be found, so it is in effect more miraculous! As for those simples whereof wee have alreadie written, for the most part they are such, as have served our turne at the bourd: or else in regard of their beautie, odour, and smell, have induced us to search farther into them, and to make triall of their manifold vertues and operations in Physicke. But yet there remaine behind many more, and those so powerfull, that they prove evidently unto us, how Nature hath produced nothing in vaine and without some cause: although the same be occult and hidden oftentimes from us, and reserved onely in her closet and secret counsell.

Chap. I.

Of certaine nations which use hearbes for procuring and preserving of beautie.

GErtes, I doe find and observe, that there bee forraine nations, who time out of mind, have ben ever accustomed to annoint their bodies with the juice of certaine hearbs, for to embellish and beautifie them, as they thought. And verely in some of these *barbarous countries, yee shall have the women to paint their faces, some with this hearbe, and others with that: yea, and among the Dakes and Sarmatians, in Transylvania, Walachia, Tartaria, and those parts, the men also marke their bodies with certaine characters. But to goe no farther than into Gaule, there groweth an hearbe there like unto Plantaine, and they call it Glastum [or Woad] with the juice whereof the women of Brittaine, as well the maried wives, as young maidens their daughters, annoint and die their bodies all over: resembling by that tincture the colour of Moores and Æthyopians: in which manner they use at some solemne feasts and sacrifices, to goe all naked.

*All such as be neither within Greece nor Italie.

Chap. II.

That clothes be died with certaine hearbs.

ANd now of late daies we know there hath been taken up a straunge and wonderfull manner of dying and colouring clothes. For (to say nothing of the graine brought out of Galatia, Affricke, and Portugall, whereof is made the royall Skarlet, reserved for princes only and great captaines to weare in their rich mantles of estate and coats of armes:) behold, the French inhabiting beyond the Alps, have invented the meanes to counterfeit the purple of Tyrus, the Skar-

A Skarlet alſo and Violet in graine; yea, and to ſet all other colours that can bee deviſed, with the
juice onely of certaine hearbs. Theſe men are wiſer (beleeve mee) than their neighbours of other
nations before them: they hazard not themſelves to ſound and ſearch into the bottome of the
deepe ſea for Burrets, Purples, and ſuch ſhell-fiſhes. Theſe adventure not their lives in ſtraunge
coaſts and blind baies, where never ſhip hath rid at anker, offering their bodies as a prey to feed
1 the monſtrous Whales of the ſea, while they ſeeke to beguile them of their food in fiſhing for
the ſaid Burrets: and all to find that, whereby as well unchaſt dames of light behaviour might ſet
out themſelves and ſeeme more proper, to allure and content adulterous ruffians: as alſo thoſe
2 gallants againe, ſquaring and ruffling thus in their colours, might court faire ladies and wedded
wives; yea, and with more eaſe entrap and compaſſe them to yeeld unto their pleaſure. But theſe
B men ſtand ſafe upon drie land, and gather thoſe hearbs for to die ſuch colours, as an honeſt min-
2 ded perſon hath no cauſe to blame, nor the world reaſon to crie out upon. Nay, our brave mini-
ons and roiotous wantons, it might beſeeme alſo to bee furniſhed therewith; if not altogether ſo
glorious to the eye, yet certainely with leſſe offence and harme. But no part it is of my deſſeigne
and intent to diſcourſe upon theſe matters at this preſent: neither will I ſtand upon the thrift and
good husbandrie that may be ſeene in ſuch a thing as this, leaſt I might ſeeme to colour any va-
nitie with a ſhew of commoditie and frugalitie: and to limit exceſſe and ſuperfluitie within the
tearms of profit and cheapeneſſe, which indeed will not bee gaged and brought within any com-
paſſe. Beſides, I ſhall have occaſion hereafter in ſome other place to make mention both of dying
ſtones, and alſo of painting walls with hearbs. As for the art and myſterie of Diers, if ever it had
C been counted any of the liberall Sciences, beſeeming a gentleman either to profeſſe or practiſe,
I aſſure you I would not have overpaſſed it in ſilence. And yet I promiſe you, this feat groweth in-
to credit every day more than other: and the *havens abroad where thoſe fiſhes be taken which
furniſh them with colours, are mightily frequented and in greater name and requeſt than ever
they were. In which regard, I cannot chuſe but ſhew and declare what account wee ought to
make of theſe dumbe tinctures in that behalfe; I meane ſuch hearbs and ſimples, whereof
there is but baſe reckoning or none at all made: for thoſe great princes which were the firſt foun-
ders and eſtabliſhers of the Romane Empire, did mightie things therewith, and emploied theſe
hearbs in the higheſt matters of ſtate. For in the affairs of greateſt importance, namely, either
in publicke ſacrifice for the averting of ſome heavie judgement of the gods threatened: or in ex-
D 2 piation of any greevous ſinne and offence committed (whether they performed divine ſervice to
their gods, or diſpatched honourable embaſſages to other States) they uſed their Sagmina and
Verbenæ: by which two words verely was meant one and the ſame thing, even ſome plaine and
common graſſe plucked up with ceremoniall devotion, turfe and all, from their caſtle hill or ci-
tadell of Rome. And this at all times was obſerved religiouſly, that they never ſent their heraulds
to the enemies of the people of Rome for to clarigat, that is to ſay, to ſummon them with a lowd
voice for to make reſtitution of that which they detained of theirs, without a turfe and tuft of the
ſaid graſſe: and evermore there accompanied theſe heraulds in their traine, one ſpeciall officer
who had the charge to carie and tender that hearbe, who thereupon was called Verbenarius.

* *Portibus augeatur auctoritas.*

E

Chap. iii.

Of graſſe Chaplets.

NO Coronets verely were there ever at Rome better eſteemed, either to teſtifie the trium-
phant majeſtie of that victorious citie (the ſoveraigne ladie of the whole world) or to give
teſtimonie of honour and reward for ſome notable ſervice performed for the Common-
weale, than thoſe which were made ſimply of greene graſſe. The crownes of beaten gold, and en-
2 riched with pearle; the Vallare and Murall Chaplets beſtowed upon brave knights and valiant
ſouldiors, who either entred the fortified campe of the enemie over trench & rampier, or mount-
ed the wals in the aſſault of a citie, came nothing neare to this: the Navall garlands given to ad-
F mirals and generals at ſea, for obtaining victorie in that kind of ſervice: the Civick coronets alſo
preſented unto ſuch as had reſcued a Romane citizen, and ſaved his life, came behind theſe: and
in one word, the Chaplet Triumphall, which they ware who entred with triumph into Rome, was
nothing comparable to theſe. And yet all theſe Guirlands abovenamed have notable preroga-
tives, and differ one from another in many reſpects. In a word, thoſe Coronets and Chaplets of
honour

honour, all ſave theſe made of graſſe, were given many times by ſome privat and particular perſons, or by the captains and generals themſelves unto their ſouldiors: yea, and otherwhiles from one Generall to another, when they were joined together in equall commiſſion, in teſtimonie of vertue and valour. G

Chap. 1111.

The ſingularitie and rare examples of ſuch Chaplets made of graſſe.

NOw, whereas other Garlands of honour and Coronets of triumph, were alwaies either ordained by a decree from the Senat in time of peace, and after the troubles of warre overblowne; or graunted by an Act of the people, being quiet and in repoſe, when daungers were paſt: this Chaplet of graſſe aforeſaid, it was never any mans hap to have, but in ſome extremitie and deſperat caſe of the whole ſtate: nor at any time adjudged to a man, but by the whole armie, confeſſing with one voice & generall conſent, That by him alone they were all ſaved from the edge of the ſword, or famine. As for the reſt, the captains and generals uſed to give them: this onely was preſented by the ſouldiours to their cheefe leader. The ſame was called alſo an Obſidionall coronet or ſeige-Garland, namely, when ſome captaine had forced the enemies to raiſe the ſiege and diſlodge, and thereby ſaved either a whole towne or campe from utter ſhame and finall deſtruction. And certes, if there was ſo great account made of a Civicke guirland, for reſcuing the life of one onely citizen of Rome (and ſuch an one perchance as was of all others the meaneſt) that whoſe fortune it was to obtaine it, he was honoured ever after with many priviledges and immunities, and counted ſacred: how highly then is he to be eſteemed, who by his owne valour and proeſſe hath ſaved many thouſands, and a whole armie of ſuch citizens? This Chaplet then, ſo ſingular and excellent, was made of the greene graſſe, or hearbs taken and gathered from the very place where a man had ſaved and delivered the beſieged. For in truth, the greateſt ſigne of victorie in old time, and of yeelding to the mercie of the enemie, was this, If the vanquiſhed did take up graſſe, and tender it unto the conqueror: for this ſerved as a confeſſion and proteſtation, That they rendered up all their interreſt which they might challenge in the earth (the mother that bred and fed them) yea, and the very right of ſepulture in her: which cuſtome I underſtand, the Germanes doe retaine and obſerve, even at this day. H I

Made of Oke leaves and branches.

Chap. V. K

What captaines they were, who alone received the honor of a Civicke Chaplet.

Lvcius Siccius ſurnamed *Dentatus*, was crowned but once with this Coronet of graſſe: notwithſtanding it was his good fortune to deſerve and obtaine foureteene Civicke guirlands: to fight with his enemie in a hundred and twentie battels, and ever to return out of the field with victorie: whereby we may ſee how rare a thing it was in times paſt, to ſee an armie thus ſaved through the valour of their captaine, for to recogniſe by this publicke preſent their onely ſavior. And ſome leaders and captaines have been honoured this way oftener than ſo. As for example, *P. Decius Mus* received two ſuch Coronets: For being a colonell and knight marſhall of the campe, hee behaved himſelfe ſo valiantly, that one was given him by the regiment or armie which himſelfe led; and another by thoſe who had beene beſieged within their fort. And how highly he eſteemed of this honourable reward, hee teſtified by his religious devotion and the ſacrifices which hee offered thereupon to the gods: for no ſooner had hee received theſe Coronets; but whereas the armie aforeſaid beſieged, and by him delivered, had beſtowed upon him over and above for his brave ſervice, one white Oxe, and an hundred others, which were brended, he ſacrificed them all unto god *Mars*. This was that *P. Decius*, who afterwards being conſull together with that ſurlie and imperious colleague of his [*T. Manlius*] ſurnamed *Imperioſus*, devowed and yeelded himſelfe to all the divels of hell for the ſafetie of his armie, and the obtaining of victorie. Moreover, that noble and renowmed *Fabius*, who ſet upright again the declining ſtate of the Roman Commonweale, with lying off and not fighting at all with *Annibal*, was crowned therfore with ſuch a chaplet, by authoritie from the Senat and people of Rome: ſuch an honor in my judgement as no man in this world can reach and attain to higher. True it is, that beforetime he had performed right good ſervice, & namely, when being Dictator, he reſcued & ſaved L M

his

A his high*Conſtable or grand maiſter of the Cavallerie, together with his whole armie: and yet was he not thus highly rewarded then, with this Coronet of greene graſſe. For in teſtimonie of thankfulneſſe, this gratuitie they whom hee had ſaved, thought at that time better, namely, to crowne him (as it were) with a new name and title to his former ſtile, calling him with one voice, Father. But the honor abovenamed was given unto him (as I ſaid) by the generall conſent as well of Senat as people, at what time as hee chaſed *Annibal* out of Italie. And in truth, never man yet was in this wiſe knowne to bee crowned by the hands (if I may ſo ſay) of the whole Empire, but himſelfe alone. This peculiar honour obtained he above all others, that this Chaplet alone was offered and preſented unto him by all the ſtates of Italie. *M. Minutius.

B

Chap. vi.

What he was, who alone of all Centurions received this Chaplet of graſſe.

BEſides thoſe abovenamed, I find that *M. Calphurnius Flamma*, a Colonell of a regiment of ſouldiours in Sicilie, was in this manner rewarded and honored with a graſſe Guirland. But never was there knowne to this day any one to have been crowned in this wiſe, of ſo baſe degree and condition as *C. Perreius Atinas*, in that warre wherein the Cimbrians were defeated, who indeed was no better than a ſimple Centurion. This Centurion having by his place the conduct of the formoſt band of a regiment of ſouldiors under Colonell *Catulus*; ſeeing upon a time certaine companies excluded out of their owne camp, by reaſon that the enemies had put themſelves betweene them and home, and there encamped; perceiving his captaine or Colonell *Catulus* aforeſaid, timorous and doubtfull to breake through the enemies campe; put on a reſolute mind, ſlew his owne Colonell, exhorted and encouraged the companies to quit themſelves like men, and follow his enſigne: and ſo he defeated his enemies, and delivered his own legion. I read moreover in the Chronicles, That the ſame Centurion over and above the foreſaid brave ornament of a graſſe Coronet, had this honor done unto him, that being clad in a long robe of purple embrodered, and aſſiſted with both the Conſuls for the time being, *Marius* and *Catulus*, hee was allowed to ſacrifice unto the gods with a noiſe of fifes and haut-boies ſounding hard by the hearth or alter fire. Furthermore, *Sylla* the Dictatour hath left in writing, That when he was lieutenant Generall under the Conſuls, and had the leading of the armie in the expedition or journey againſt the Marſians, the whole armie preſented unto him a Chaplet of graſſe, before the citie of Nola. And in very truth he cauſed this to be pourtraied in a painted table within a houſe of pleaſure which hee had in Thuſculum, the ſame that afterwards *M. Tullius Cicero* was maiſter of. Which if it were true, the more ſhame deſerved hee in my conceit: and I hold and pronounce him ſo much the more accurſed and deteſtable, for taking this crowne from his owne head, and looſing ſuch a brave badge of honor, in proſcribing, overthrowing, baniſhing, and murdering afterwards, a greater number of citizens (without all compariſon) than thoſe ſoldiors came to, whoſe lives he ſaved, at what time as hee tooke that garland firſt upon his head. Let him vaunt as much as hee will of the ſaid Coronet, as alſo of the prowd and vaineglorious title of Fœlix, *i.* Happie, (which addition or ſurname he tooke upon him and cauſed to bee put into his ſtile) yet, when as through his tyrannie he held beſieged thoſe Romane citizens whom he had proſcribed and confined into all parts of the world, ſurely he forewent all and yeelded that crowne unto *Sertorius*.

C D E F

Moreover, *M. Varro* doth report, That *Scipio* ſurnamed *Æmilianus*, was honoured with an Obſidionall Coronet in Affricke (the ſame yeare when as *Manlius* was Conſull) for ſaving three cohorts beſieged: as alſo three companies beſides which hee led forth to deliver the other, and by whoſe meanes he forced the enemie to breake up his ſiege. This is to bee ſeene and read in a Table, which *Auguſtus Cæſar* late Emperour of famous memorie, cauſed to bee hanged up at the baſe or foot of the ſaid *Scipioes* ſtatue erected in the Forum or publick hall which himſelfe built. As for *Auguſtus* himſelfe, the Senat crowned him with an Obſidionall Chaplet, upon the thirteenth day of September, that yeare when he was Conſull with *M. Cicero*, the ſonne of that great *Cicero* the Oratour. Whereby we may ſee, that a Civicke Chaplet was not thought ſufficient nor any waies comparable to this Coronet. And ſetting aſide theſe abovenamed, I do not find in hyſtories, of any one who was crowned with a greene chaplet of graſſe. Now, this you muſt note withall, That there was not one certaine hearbe ſet out and appointed for theſe honorable Guirlands: but look what kind of herbage grew then in the place beſieged and where the danger was,

that

that very ſame they tooke, were they never ſo baſe weeds and of no reckoning: for as contemptible otherwiſe as they were, yet being once emploied to this uſe, they ennobled and adorned the perſon himſelfe who ware them in a Chaplet. And certes, the leſſe marvell I have if theſe things bee unknowne to us nowadaies, ſeeing as I doe, how little or no account is made even of thoſe things which make to the maintenance and preſervation of our health; to the cure of all dolourous greefes and maladies of the bodie; yea, and to the prevention of death it ſelfe. But what man is there well given and honeſtly minded, who can contain and hold his peace, having ſo juſt cauſe to reprove and rebuke the manner of the world in theſe our daies? Firſt and formoſt, our life was never ſo coſtly as now it is, in regard of the dainties, delights and ſuperfluities, which muſt bee maintained, if we will live to the faſhion of the time: and for to enjoy theſe pleaſures onely, wee hold our lives more ſweet and precious. Never were men more deſirous of long life, and never leſſe carefull to entertaine the means of long life. The governement of our health wee commit to the charge of others, and ſtraungers wee credit with our owne bodies, and yet ſlacke ynough and negligent are they, to ordaine according to our truſt & confidence, that which indeed ſhould doe us good. Thus the Phyſicians are provided well for: they thrive alone and goe away with the gaines by this meanes. Oh good God, to ſee the follie and vanitie of man! Nature having put ſo many good things into our owne hands as ſhe hath, and willing that wee ſhould enjoy them for our health and pleaſure: yet we (to our great ſhame and rebuke be it ſpoken) are ſo unhappie, as to commit our ſelves to other mens tuition, and live under their warrantize and aſſurance. Full well I know, that I for my part alſo, ſhall have but ſmall thankes of many a one for all my paines taken in writing this hiſtorie of the world and Natures workes: nay, I am aſſured that I make my ſelfe a laughing ſtocke, and am condemned of them for ſpending and looſing my time in ſuch a frivolous peece of worke as this is. Howbeit, this is yet my comfort and no ſmall contentment I take herein, that my labors and travels (exceſſive and infinit though they be) cannot be deſpiſed, but the contempt will redound likewiſe to dame Nature her ſelfe. And yet ſhee againe, as a kind and tender nource over mankind, hath not failed (as I will declare hereafter) for our good, to endue the very weeds which wee tread underfoot with medicinable vertues, yea, and hath beſtowed upon thoſe which otherwiſe we hate and dare not approch, but with carefull heed (for the ſhrewd prickes and thornes which they carie about them) ſingular properties to cure diſeaſes. For over and beſides thoſe whereof I made mention in the booke going next before this, there bee other hearbs of that pricking kind, which are ſo wonderfull in their operation and effects, that I can never admire ſufficiently and comprehend her providence appearing in them. Furniſhed ſhee had the earth, with ſmooth & prickleſſe plants inough, in the nature of meats, for to content our tooth & ſatisfie our appetite: ſhe had engraven and lively painted in flowers, notable properties in phyſicke for to recover and maintaine our health; and by the ſingular beautie which ſhe gave unto them, to allure the heart and eye of man to looke toward them, ſaying (as it were) Come and gather us: wherein ſhe had made a good medley of profit and pleaſure together. And when ſhee had thus done, ſhee ſtaied not there, but deviſed to bring other hearbs, hideous to the eye, and untractable in hand: As if in the forming of them in that faſhion, we might heare her to give a reaſon, Why ſhe ſo did? ſaying after a ſort unto us in an audible voice, That ſhe made them with prickes and thornes, becauſe ſhe would not have the foure-footed beaſts (as hungrie and greedie after meat as they be) to eat them downe, That the ſhrewd hands of ſome ungracious folke, who can let nothing ſtand, might not be ever and anone plucking and twitching at them for wantonneſſe, That people ſhould not go careleſſely trampling upon them with their feet: finally, For fear that birds pecking and ſetling aloft upon their tender braunches would ſlive them down or knap them aſunder. Therefore (I ſay) with theſe prickles, ſerving in ſtead of weapons as well defenſive as offenſive, ſhe hath both protected and alſo armed them: and all to keepe them ſafe and ſure, for the health of man, and to doe him ſervice. Lo, how even that which we hate and ſeeme to abhor in theſe hearbs, was deviſed for our comfort and benefit, if wee had the grace to ſee it.

Chap. vii.

The medicinable vertues of other flowers and hearbs ſerving for Chaplets. Alſo of Erynge.

*Sea-Holly. AMong thoſe hearbes which beare pricke, *Erynge or Eryngion, is ſingular: for a ſoveraigne hearbe it is againſt ſerpents, and all poyſons whatſoever, as if it grew for nothing els. But to come

A come to particulars, for ſtings and bitings of venomous creatures, the root thereof to the quantitie of one dram, is taken in wine. And in caſe (as moſt times it falleth out) that a fever follow upon ſuch accidents, then the patient muſt drinke it with water. A ſpeciall and effectuall propertie it hath againſt certaine land-ſnakes called Cherſydri, and venomous todes, if it be reduced into a liniment, and ſo applied to the ſore. But *Heraclides* the Phyſician is of opinion, That if the ſaid root bee boiled in the broth of a Gooſe, it is of more efficacie than all other, againſt the Toxica and Aconita. But whereas others doe boile it in ſheere water againſt the poyſons Toxica, *Apollodorus* would have a frog ſodden withall. The hearbe it ſelfe is of ſubſtance hard, branching much, full of leaves, and thoſe beſet with prickes. A ſtem or ſtalke it carieth, parted by knots and joints, a cubit high and ſomewhat more. Moreover, as there is white Erynge, ſo you ſhall have of it black:
B The root is odoriferous. Eryngion verely commeth up ordinarily of ſeeds and by ſetting. But it groweth alſo in rough and ſtonie places of the owne accord. And that which we ſee along the ſea ſhore, is harder and blacker than the reſt, leaved alſo like common Ach or Perſeley.

Chap. viii.

Of the hearbe or thiſtle commonly called Centum-capita, i. the hundred heads.

AS for the white Erynge, our countreymen call it in Latine Centum-capita. But they bee all of one and the ſame operation and effect. And the Greekes verely make their ordinarie meat as well of their ſtalkes as roots, both waies, to wit, either raw or boiled, as they liſt.
C Certes, there be wonders reported of this hearbe, namely, That the root of this white Eryngion, (which is very geaſon and hard to be found) reſembleth one while the male ſex, and otherwhiles the female, of our kind. But if it chaunce that a man doe meet with that Eryngion which is like unto that member which diſtinguiſheth him from a woman, he ſhall be very amiable and beloved of women. Which was the reaſon (men ſay) that ladie *Sappho* was ſo enamoured upon the yong knight *Phao* of Lesbos. And verely, as touching this hearbe, not onely the Magicians, but the diſciples alſo and followers of *Pythagoras*, tell us many vaine and fooliſh tales.

But to come indeed to the uſe of it in Phyſicke. Over and beſides thoſe vertues and properties which I have related alreadie, good it is to reſolve ventoſities: it eaſeth the gripes and wrings in the bellie: it cureth the diſeaſes and debilitie of the heart: it helpeth the ſtomack and liver. For
D the midriffe and precordiall parts, it is very holeſome taken in honied water: and for the ſpleen, in vinegre and water together. Alſo drunk in mead or honied water aforeſaid, it is ſingular for the kidneies, the ſtrangurie, the crampe or cricke that pulleth the head of a bodie backward: for other ſpaſmes alſo and convulſions: for the loines, the dropſie, and the falling ſickneſſe. Soveraigne it is moreover for womens monthly fleurs, whether they doe ſtay upon them, or contrariwiſe run exceſſively from them: and in one word, it cureth all the accidents and infirmities of the matrice. Being applied as a liniment with honey, it draweth forth any offenſive thing ſticking within the bodie. And if it be laid too with ſalt, lard, or hogs greaſe, and ſo incorporat into a cerot, it healeth the kings evill, the ſwelling kernils behind the eares, and the flat biles and botches. It rejoineth alſo the fleſh that is gone from the bone: and finally, ſoudereth and knitteth broken bones or fra-
E ctures. Taken before a man ſit downe to eat or drinke, it preſerveth him from ſurfet or drunkenneſſe: and bindeth the bellie. Some of our Latine writers would have it to be gathered a little before the Summer Solſtice, ſaying moreover, That if it bee applied with raine water, it helpeth all the infirmities incident to the nape of the necke: and by their report, if it be bound to the eyes, it cureth the pin and web.

Chap. ix.

Of Acanus and Liquirice.

F SOme there be who take Acanus for a kind of Eryngium. And they deſcribe it to bee a low hearbe, and yet growing broad and large, full of prickes and thornes, and thoſe likewiſe bigger than ordinarie: Being applied outwardly, wonderfull effectuall it is (by their ſaying) to ſtanch bloud. Others there are, who have thought Erynge and Liquirice to bee all one, but they are deceived. Howbeit, for ſome reſemblance that is betweene them, I thinke it not amiſſe to ſet downe the deſcription thereof immediately after theſe Erynges. Doubtleſſe, this Liquirice alſo is

to

to be counted among these thornie plants, for that the leaves stand*pricking up sharp-pointed; the same are fattie, and in handling gummie and glewie. It putteth foorth many braunches, and those two cubits high: it carieth a flower in manner of the Hyacinth, and beareth fruit resembling bals of the bignesse of those which hang upon the Plane tree. The excellent Liquirice is that which groweth in Cilicia: the next for goodnesse commeth from Pontus: and hath a sweet root which onely is used in Physicke. Taken up this is and gathered at the setting or occultation of the Brood-hen star, and is found running along in the ground in manner of the Vine root: in colour like to the Box tree. That which is duskish and somewhat blacke, is thought to be the better: like as the lithe and pliable root which will wind and turn every way, is preferred before that which is brittle and easie to breake. Great use there is of it in those medicines which be*held under the tongue, so to resolve and melt leasurely, namely, after it hath been sodden to the thirds: yea, and otherwhiles boiled to the height and consistence of hony. Sometimes they use to bruse it; and in that manner they doe lay it upon wounds, where it doth much good: as also if it be applied to all the diseases and accidents befalling to the throat and jawes. The juice of Liquirice reduced to a thicke consistence, if it be put under the tongue, is singular for to cleare the voice. In like manner it is supposed very wholesome for the breast and liver. And therewith (as I have said before) both thirst and hunger may be slaked and allaied. Which is the cause that some have called it Adipson: and in that regard ministred it to those persons who be fallen into a dropsie, for to prevent and take away their thirstinesse. Therefore it is thought to bee a proper remedie for the diseases of the mouth, if it bee either chewed, or otherwise cast and strewed upon the ulcers therein: and so it cureth the excrescences also and exulcerations about the roots of the nailes. Moreover, it healeth the excoriation and soreneſſe of the bladder, assuageth the paine of the kidneies, cureth the swelling and aking piles, the fissures also in the seat, and finally the ulcers of the privie parts. Some Physicians have prescribed to drinke in a Quartan ague, the weight of two drams of Liquirice, & one of Pepper, in a draught of water to the quantitie of a small pint or hemina. This root being chewed, staieth bleeding in a wound. To conclude, some have written that it expelleth the stone and gravell.

*Echinatis. It seemeth that Plinie never saw Liquirice, but read ἐχίνοις for ὀχνοις, i. Lentisci: and indeed the leaves are like to those of the Lentiske tree.

*In linguæ subditis. Such as be our Ecligmata or Lochs.

G H I

Chap. X.

Of the Caltrop thistle Tribulus. The sundrie kinds therof, and the medicines which they yeeld.

K

Some of these Thistles come up in gardens: others grow in and about rivers onely. The juice which is drawne from these, is thought to bee good for the eyes: for this hearbe being as it is of a cooling nature, is a singular remedie for inflammations and gathering of impostumes. A good medicine for all ulcers, but those especially which break out of themselves in the mouth: it cureth likewise those of the amygdales or almonds of either side of the throat. If it be taken in drink, it fretteth & breaketh the stone. The Thracians dwelling upon the river Strymon, feed their horses fat with the leaves of this hearbe: and live themselves with the kernels or fruit thereof, making a kind of sweet bread therewith, which also bindeth the bellie. The root if it be gathered by the chast and pure hands of a virgin discusseth and dissolveth the kings evill. The seed if it be tied to the swelling vaines, assuageth their pain. Lastly, being beaten into pouder and cast into water, it killeth the fleas in any place where that water is throwne or sprinckled.

L

Chap. XI.

Of Stœbe and the medicines which it affourdeth.

A kind of Matfellon or Knapweed.

Stœbe, *which some call Phleon, boiled in wine, is a soveraigne remedie for eares that run with atter: likewise for bloudshotten eyes, especially upon a stripe or stroke given. Being ministred by way of clyster, it is good for the bloudie flix and the exulceration of the guts.

Chap. XII.

M

Of Hippophyes and Hippope, with their medicinable vertues.

Hippophyes is an hearbe growing in gravellie and sandie places, and namely along the sea side, armed with white prickes or thornes: it beareth berries by clusters after the manner

of

A of Ivie, and those be partly white and partly red. The root is full of a certain juice, which is good either to be condite and confected alone, or els to be reduced into Troches with Ervile meale: this being taken to the weight of one Obolus, purgeth cholerique humours; and a most holesome medicine it is, especially with honied wine. *Ervi farina.*

Another hearb there is, named Hippope, which neither riseth up in stalke, nor beareth floure, but hath leaves onely, and those small. The juice also of this hearbe, is wonderfull good for those who are in a dropsie: where it is to be noted, That these two hearbs should have some especiall properties respective to the nature of horses, considering both their names are derived from nothing else: for in very truth, some things there be which Nature hath brought foorth as appropriat remedies for certain particular beasts, whereby we may see her divine power, and how
B well appointed she is and provided for to bring forth medicines of all sorts; so as the deapth of her providence cannot be sounded, neither are we able sufficiently to admire her wit and discretion, in disposing and digesting her remedies according to sundry kinds of creatures, according to divers causes, and different seasons: insomuch as the remedies serving one, are not fitted for another, neither are they of the same effect and operation at all times: nay, there is not a day almost in the yeere throughout, but it yeeldeth a remedie respective unto it.

Chap. XIII.

Of the Nettle, and the medicinable vertues thereof.

C IS there any thing more hated and odious than the Nettle? and yet to say nothing of the oile made of it in Ægypt (according as we have shewed heretofore) endued shee is and furnished with many good properties serving for Physicke. For first, as touching Nettle seed, *Nicander* affirmeth, That it is a very countrepoison against Hemlocke, venomous Mushroms, and Quicksilver. *Apollodorus* addeth moreover and saith, That being boiled in the broth of a Tortoise, it is singular good for the poison of Salamanders: also that it is contrarie to the pernicious nature of Henbane; and the deadly poison of serpents, and namely of scorpions. Even that very bitternesse and mordacitie which the Nettle hath, causeth the Vvula in the mouth which is falne, to knit up againe: the matrice also which is over-loose and beareth downe, to arise into the place; yea and
D the tuill or fundement in children hanging foorth of the bodie, to returne and abide where it ought to be, onely with touching these parts therewith. If the legs be rubbed, and the forehead especially with Nettles, it is a good means to awake them out of their drowsie and dead sleepe, who are surprised with a lethargie. The same being applied with salt, is passing good for the biting of dogs. If it be bruised and put up into the nosthrils, it stancheth bleeding at the nose; but principally the root of it. If it be tempered with salt, it mundifieth cancerous and foule filthie ulcers: likewise it helpeth dislocations and bones out of joint: it discussseth or ripeneth botches in the emunctories, and the swelling kernels behind the ears; and healeth up the places where the fleshie parts be gone from the bones. Nettle seed taken in wine-cuit (as a drinke) openeth the matrice when it is readie to strangle or suffocat a woman: and beeing applied with wine, it
E staieth bleeding at the nose. If one drinke Nettle seed after supper, with honey and water, to the quantitie of two oboles weight, it openeth the passages and maketh way for to vomit with greater facilitie: but the weight of one obolus taken in wine, refresheth those who have a lassitude or wearinesse upon them. The same being parched against the fire and drunke to the measure of one Acetabulum, is singular for the imperfections of the matrice: and in cuit, it withstandeth the ventosities and inflations of the stomacke. Given inwardly with hony in the forme of a loch, it doth them good who labour for wind, and cannot take their breath but sitting upright: and after the same manner it cutteth fleame and cleanseth the breast of it. Being applied in a bag, togither with lineseed, it taketh away the stitch and paine in the sides: but some put hyssope thereto, and a little pepper. A liniment made therewith, cureth the splene. Beeing parched or rosted
F and so eaten with meat, it keepeth the bodie soluble. And *Hippocrates* affirmeth, that the said seed is very good to be taken in drinke, for to cleanse the matrice in women: and beeing so parched and given to the quantitie of one Acetabulum in sweet wine cuit, it allaieth the griefe and paine of the said part, in case withall there be a cataplasme applied to the region thereof, togither with the juice of Mallows. If it be taken in Hydromel, *i.* honyed water, togither with salt, it expelleth

(by his saying) the worms in the belly. Applied in a liniment to the bare and naked places of the head, it causeth the haire to grow againe, and bringeth all to the former beautie. Many doe use to make a cataplasme of Nettle-seed and old oile; or els stampe the leaves together with Beares grease, for the paine of the gout: and verely for that purpose, as also for the splene, the root pouned with vinegre, is no lesse effectuall. Beeing boiled in wine, it discusseth and driveth downe risings in the groine, and such like emunctories, so it be laid too with old hogs grease salted. But the same root drie, is a verie depilatorie, and fetcheth haire off. *Rhonias* (the naturall philosopher and physician) in a severall treatise which he made in the praise of Nettles, professeth, That he knoweth not the like remedie to the Nettle, boiled first and then condite, for the windpipe, the cough, the distillation and flux of the belly, the stomacke, the biles and botches in the emunctories, the swelling and enflamed kernels behind the eares, and kibed heels. The same with oile, procureth sweat: and sodden with muscles, and such like shell-fishes, it mooveth to the stoole: with ptisane or barley broth, it purgeth the breast, and sendeth downe womens tearms: applied with salt, it restraineth ulcers that be corrosive and apt to run and spread farther. The juice also of the Nettle, serveth to many uses; for being pressed forth and laid as a liniment to the forehead in a frontall, it stancheth bleeding at the nose. The same taken in drinke, provoketh urine, and breaketh the stone: but if one gargle with it, it staieth the Vvula from falling. As for the seed, it ought to be gathered in harvest time: and that which is brought from Alexandria, is esteemed best. For all the particular diseases above rehearsed, the kinder and gentler Nettles also, even those that be young and tender, are knowne to be of good operation; but principally that wild kind beforesaid: and this propertie moreover it hath, To rid away the leprosie out of the face, if it be taken in wine. Finally, if a foure-footed beast will not abide to be covered or served with the male of that kind, an ordinarie practise it is, to rub the mature or shap with a Nettle, for that will make her stand to the fellow.

Chap. xiiii.

Of Lamium, and the medicinable vertues thereof.

As touching that dead Nettle, which among the other kinds wee named before Lamium, i. Archangell, it is the mildest of all others and most tractable, for the leaves bite not nor sting at all. The same, if it be applied with some corns of salt, to contusions and bruises, to deepe burns, the Kings evill, swellings, gouts, and wounds, cureth them all. The white that it hath in the mids of the leafe, is singular for S. *Anthonies* fire, the shingles, and such like. Some there be of our Latine writers, who treating of Nettles, have couched them in their ranks respectively to the time, saying, That the root of a Nettle which commeth in the Autumne, cureth the tertian ague; but it must be tied fast to the Patient: and these ceremonies are to be observed also in the taking it foorth of the ground, That the partie be named for whome it is gathered; the fever also, Of what type or kind it is; yea and who be the parents of the sicke person; and then hee or shee shall be sure to be delivered of that disease. The said root, with the same circumstances, is of the like operation to drive away the quartan ague also. The selfesame authors doe affirme moreover, That the root of a Nettle beeing applied with salt, draweth foorth all thorns and shivers that sticke within the flesh. Also, that a cataplasme of the leaves and hogs grease incorporat togither, doth resolve the scrophules or swelling kernels called the Kings evill: or if they are come to suppuration, eateth and worketh them forth, and doth incarnat and fill up the place againe.

Chap. xv.

Of the hearb Scorpius: the sundrie kinds thereof, and the medicinable properties.

* Scorpiacides.

There is an hearbe called * Scorpius, which tooke that name of the resemblance that the head hath to a scorpions taile. Few leaves it beareth; but (according to the name) it is good against the sting of scorpions. Another hearbe there is of the same appellation, and of like effect to the other; but it sheweth no leaves at all: the stalke is smooth, and resembleth garden Sperage: in the top or head whereof, there is a pricke to be seene like a sting, which gave occasion of the foresaid name.

Chap.

A

Chap. xvi.

Of Leucacantha, and the vertues thereof good in Phyſicke.

THe Greeks, ſome call this Thiſtle, Leucacantha, or the white Thiſtle; others, Phyllon: ſome Iſchias, others Polygonaton: but be the name what it will, it hath a root reſembling that of * Cyperus, which if it be chewed in the mouth, allaieth the tooth-ach. *Hiceſius* ſaith likewiſe, That if either the ſeed or the juice of the root thereof, bee taken in drinke to the weight of eight drams, it aſſuageth the paine of the ſides and loins. The ſame alſo cureth ruptures, convulſions, and cramps.

* or *Cyperus.*

B

Chap. xvii.

Of Helxine or Perdicium, called alſo Parthenium or Sideritis, and the vertues medicinable.

AS for Helxine, ſome call it Perdicium, becauſe Pertridges delight moſt to feed therupon: others name it Sideritis; and many give it the name of Parthenium. Leaves it carrieth of a mixt forme and reſemblance, between Plantain and Horehound. The branches or ſmall ſtalks grow in thicke tufts, and thoſe be of a light reddiſh colour: the ſeed in the head, of a Bur kind which ſticketh to folkes cloaths, whereupon they would have it to be called Helxine. But in the former booke I have deſcribed the forme of the right * Helxine or Parietarie indeed. The propertie of this hearbe, is to give a tincture or die to wooll: it healeth the ſhingles and S. *Anthonies* fire: it cureth ſwellings, and all apoſtemations of humours, yea and alſo burnes. The juice thereof incorporat with ceruſe or white-lead, and ſo applied, ſerveth greatly for biles and botches, S. *Anthonies* fire, tumours, gatherings and riſings in the fleſh; yea and helpeth them whoſe throat begins to ſwell. Alſo if a man take the quantitie of one cyath thereof, it cureth inveterat and old coughs: it healeth all infirmities either occaſioned by phlegmaticke humors, or els incident to moiſt parts: like as with oile roſat it is a proper medecine for the accidents of the amygdales about the paſſage to the throat; and for the ſwelling of veins. Moreover, if it be reduced into the forme of a cerot, with goats ſuet and wax of Cypres, and ſo applied, it cureth the gout. Moreover, Perdicium or Parthenium (for Sideritis is another hearbe) our countreymen call in Latine, * Vrceolaris; of others, Aſtericum. In leafe it is like to Baſill, ſave onely that it is blacker: it groweth upon tile-houſes, and old decaied walls, and ſuch ruinous places. Being beaten into powder & applied with corns of ſalt, it hath the ſame operation that the nettle Lamium, and cureth the ſelfeſame diſeaſes; and the one is uſed in like ſort as the other: and if the juice be drunke hote, it is ſingular for inward and ſecret impoſtumes full of filthie matter, and driveth them outward. Alſo it is excellent for ulcers, ruptures, and bruiſes, whether it be that one hath tumbled headlong from ſome high downfall, or that he hath been cruſhed by the overthrow of ſome waggon or chariot. It fortuned that a Page of *Pericles*, a prince of the Atheniens (whome he loved entirely) having climed up to the top of the lanterne or ſpire of a temple which the ſaid prince built in the caſtle or cradle of Athens, fell downe from thence; who was cured by the means of this hearbe, revealed unto *Pericles* in his ſleepe by the goddeſſe *Minerva*: whereupon it tooke the name firſt, of Parthenium, and is conſecrat unto the ſaid goddeſſe. This is that Page whoſe molten ſtatue is to be ſeen at this day made of braſſe: this is (I ſay) that noble and famous image called * *Splanchnoptes*.

C

D

E

* Parietarie of the wall.

* Where, to ſay a truth, he deſcribeth *Helxine* for *Ixine*, or *Chamæleon* the white.

* Dioſcor. *Cerato Cyprino.*

* or *Vitraria*, becauſe it is uſed to ſcoure glaſſe and pipkins withall.

* Made with a deviſe to blow coles & kindle fire for to roſt the inwards of beaſts ſacrificed: or as ſome thinke, it was the proper name of that youth.

Chap. xviii.

Of Chamæleon the hearb, the ſundrie kinds thereof, and the vertues medicinable.

F

COncerning Chamæleon, ſome there be who name it Ixias: whereof be two kinds: The whiter hath the rougher leaves: it creepeth cloſe by the ground, and ſetteth up ſtiffe prickles in manner of an Vrchin: the root is ſweet in taſt, but of a moſt ſtrong ſent. In ſome places it ingendreth a white kind of gum or clammie glew, under the wings or armepits (as it were) of the leaves, after the ſame manner as Frankincenſe is ſaid to breed, but eſpecially about the

riſing of the Dog-ſtar: and for that it is like to a kind of birdlime, it is called Ixia: our women uſe G
this inſtead of Maſticke. And the reaſon why this hearbe is named Chamæleon, is by occaſion of the variable leaves which it beareth: for according to the nature of the ſoile where it groweth, it chaungeth hew; whereby in one place you ſhall have it blacke, in another greene; here you ſhall ſee it looke blew, and there yellow, and evermore altering the colour. Of which Chamæleons, the white cureth ſuch as are in a dropſie, if the root be boiled, and the juice thereof taken to the quantitie of a dram in ſweet wine cuit. The meaſure of one acetable of the ſame juice, if one drinke in a greene harſh wine made of the hedge unripe grape, wherein certain bunches of Origanum have lien infuſed, it is thought to be a ſingular remedie to kill the wormes that breed in the guts. It availeth much alſo to helpe thoſe who piſſe with difficultie: and yet this juice beeing given to doggs or ſwine in barley groats, killeth them. If there bee water and oile mingled H
thereto, it draweth rats and myce to it, but it is their bane, unleſſe preſently they drinke water. Some preſcribe for to cut the root thereof into thin roundles, and to keepe them enfiled up, or hanging by a ſtring, and then to ſeeth them; for to be eaten againſt the flux of humours, which the Greeks name Rheumatiſms. Of the blacke kind, ſome have named that the male, which hath the purple floure; and the female, with the violet colour. They all grow up with one ſtem and no more, and the ſame is a cubit high, and a finger thicke. The roots are good to heale ringworms, tettars, and ſuch like wild-fires, if they be ſodden togither with brimſtone and Bitumen: but if the ſaid root be chewed in the mouth, or a collution be made therewith ſodden in vinegre, it faſteneth the teeth which ſhake and be looſe in the head. The juice of this root healeth the ſcab or mange in foure-footed beaſts. Herewith alſo folke uſe to kill the ticks that breed in dogs: but it I
ſtoppeth the wind of heifers and young ſteers in manner of a ſquinancie: and therefore of ſome it is called Vlophonon and Cynozolon, in regard of the ſtrong and ſtinking ſmell that it hath. Theſe Chamæleons doe beare a certaine viſcous gum, moſt proper for ulcers. And the roots of all the ſort of them, as well blacke as white, are ſingular againſt the poiſon of ſerpents.

Chap. xix.

Of Coronopus or Harts-horne, with the medicinable vertues thereof.

Coronopus is an hearb bearing long leaves, and thoſe cloven into certain fiſſures & knags: and howſoever it groweth wild, yet otherwhiles it is ſet and ſowne in gardens, for the excel- K
lencie of the root; which beeing roſted under the aſhes, is ſoveraigne for the flux, and weakeneſſe of the ſtomacke.

Chap. xx.

Of Orchanet or Alkanet, as well the right as the baſtard, and their properties in Phyſicke.

The root of Orchanet is much uſed about medicines: of the thickneſſe it is of a finger: it will rend and cleave in manner of the papyr reed: and it coloureth the hands of as many as handle it, with a red and bloudie colour: it prepareth wooll and woollen cloth for to L
take rich and deepe colours. If it be incorporat into the forme of a cerot, it healeth ulcers, eſpecially in old men; as alſo places that be burnt. It cannot bee reſolved in water, but it is oile that muſt diſſolve it: and verely this is a good experiment of that which is true and nothing ſophiſticat. A dram thereof given in wine to drinke, is ſingular good for the paine in the kidnies: but in caſe the Patient have a fever upon him, then it ought to be taken in the decoction of * Balanos. In like manner is it to bee uſed in the opilations or obſtructions of the liver, of the ſplene, and in the jaundiſe. A liniment made of it and vinegre, cureth the leproſie, and the red pimples ariſing in the face. The leaves ſtamped with honey and meale untill they be incorporat togither, and ſo applied as a cataplaſme, are thought to be good for diſlocations: but if they be taken inwardly to the quantitie of two drams in honied wine, they bind and knit the belly. The root boiled in M
water, is ſaid to kill fleas.

* Haply hee meaneth *Phœnicobalonos, id eſt*, the Ægyptian Date: or *Oxyphœnices*, our Tamarinds, a kind of Dates appropriat for agues.

Another hearb there is much like unto it, and thereupon called Pſeudanchuſa [*i.* baſtard Orchanet] of ſome, but of others Enchuſa or Doris; and many other names it hath beſides. More full of downe or hairie moſſe it is, and leſſe fattie; but the leaves are ſmaller, more ranke and

feeble.

A feeble. The root yeeldeth no oleous ſubſtance, but a reddiſh juice; wherein it differeth from the right Anchuſa or Orchanet. The leaves or ſeed being taken in drinke, is a moſt effectuall countrepoiſon againſt ſerpents. The ſubſtance of the leaves beeing applied to the places which bee ſtung, are ſoveraigne for to cure and heale them up. The very hearb it ſelfe chaſeth away all poiſon of ſerpents. There is a drinke made therof, commended highly for the chine or ridge-bone of the backe. The Magicians doe preſcribe the leaves to be bound unto ſome part of the Patient againſt a tertian ague, with this charge, That they be gathered with the left hand, and that in the gathering, the partie or Patient for whoſe ſake they are gotten, be named.

Chap. xxi.

B *Of Onochiles, Anthemis, Lotos, and Lotometra: of Turnſoll-Tricoccus: of Adiantum, and Callitrichon.*

ANother hearbe there is, particularly named Onochiles, which ſome call Anchuſa; others Arcebion or Onochelis; ſome Rhexias, and many Enchuſa: a ſmall hearbe this is; it carrieth a purple floure, leaves and braunches rough: a root in harveſt time as red as bloud, otherwiſe bleke; and groweth in ſandie grounds: effectuall it is againſt ſerpents, and Vipers moſt of all others, both in the root and leafe, as well eaten with meat as taken in drinke. In the full ſtrength it is in harveſt. The leaves if they be bruiſed or ſtamped, doe yeeld the ſavour and ſmell of a Cucumber. If the matrice of a woman be ſlipt downe, a draught of three cyaths ther-
C of, doth reduce it up into the place: and togither with hyſſope, it driveth out the broad wormes in the belly. For the paine of the kidnies or the liver, it ought to be taken in mead or honied water, if the Patient have an ague withall; otherwiſe in wine. The root brought into a liniment, cureth the lentils or red ſpots, yea and the infection of the leproſie. And it is ſaid, That as many as have it about them, cannot be ſtung by ſerpents. There is yet another Orchanet or Anchuſa like unto this, in regard of the red floure which it beareth; howbeit a leſſe hearbe than the other, having the like operation, and emploied in the ſame uſes. It is reported, That if one chew it in his mouth, and ſpit it forth upon a ſerpent, the ſame will ſurely die thereupon.

As touching Anthemis, [*i.* Camomile] *Aſclepiades* the Phyſician doth highly praiſe and commend it. Some name it Leucanthemis, others Leucanthemus; and there be, who give it
D the name Eranthemon, becauſe it flouriſheth in the Spring: others againe name it Chamæleon, for the ſent or ſavour that it hath of an apple: many call it Melanthemon. Three kinds there be of it, differing onely in the flours (for none of them exceed an hand-breadth in heigth) which be ſmall, and in forme reſemble thoſe of Rue: howbeit, theſe floures be either white, yellow, or red. In a leane ground and neare to beaten paths, this hearbe loveth to grow. Gathered it is in the Spring, and laid up for to ſerve in guirlands: at which time the Phyſicians alſo ſtampe the leaves and make them up into Troſches: ſo doe they alſo by the floure and the root. This vertue they have, That if they be all mingled togither to the weight of one dram, they are thought to be a ſoveraigne remedie againſt the ſting of all ſerpents. This hearb expelleth dead infants within the mothers wombe, if it be taken in drinke. It bringeth downe alſo the monthly fleurs of wo-
E men; provoketh urine, and ſendeth forth the ſtone and gravell. Being chewed, it diſſolveth ventoſities, it cureth the obſtructions and defects of the liver, it helpeth the jauniſe, healeth the fiſtuloes between the angle of the eye and the noſe, and generally all running ſores and mattering ulcers. But of all theſe kinds, that which beareth the red purple floure hath moſt effectuall operation for the ſtone: and indeed, both the leaves, and alſo the braunches of this Camomile, are ſomewhat larger than of the reſt: and ſome there be, who give this a name by it ſelfe, and call it Eranthemon. As for thoſe who take Lotos to be a tree onely, may be convinced even by the authoritie and teſtimonie of *Homer*, who among other hearbs growing for the delight and pleaſure of the gods, hath named Lotos as principall. The leaves of this hearbe incorporat with honey, and ſo applied, cure the cicatrices or ſcars in the eye; the ſpots alſo appearing therein, and diſſol-
F veth the cloudie skins which overcaſt the ſight. There is a kind of Lotos named Lotometra, comming of the garden Lotos: it carrieth a ſeed like to Millet, whereof in Ægypt the Bakers make bread; but they work and knead the floure of this ſeed with water or milke. There is not any bread in the world (by report) more holeſome and lighter than this, ſo long as it is hot; but being once cold, it is harder of digeſtion & becommeth weightie and ponderous. This is known for certain,

that as many as live thereof, are infested and troubled neither with the dysenterie or bloudie flix, ne yet with the troublesome offers and streins to the seege without doing any thing, nor any other diseases of the belly: and therefore it is counted a principall remedie for those maladies. Concerning Tornsoll, I have oftentimes related the wonderfull nature thereof, namely, how it turneth about with the Sun, although it be a close and cloudie day (so great is the love of this hearb to that planet:) and in the night season for want of the Suns presence, as if it had a great misse thereof, * it draweth in and shutteth the blew floure which it beareth. Two kinds there be of this Heliotropium or Turnsoll: of which, the lesse is called Tricoccum; the other, Heliosco-pium. Of the twaine, this later is the taller (and yet neither of them both exceedeth halfe a foot in heigth) and putteth foorth braunches from the very root. The seed of this greater sort lieth within a little cod, and is gathered in harvest time: it groweth not but in a fat soile and well manured; whereas Tricoccum commeth up every where. I find, that if it be boiled, it is a pleasant and delectable meat; but sodden in milke, it looseneth the belly gently and with ease: for otherwise the bare colature of the decoction in water, if it be taken, purgeth most extremely. The juice of the greater kind, ought to be drawne or gathered in Summer at noontide; which, if it be tempered with wine, becommeth more strong and effectuall. A propertie it hath, being mingled with oile of Roses, to mitigat head-ach. The juice drawn out of the leafe, medled with salt, taketh away werts: whereupon our Herbarists have called the hearbe in Latine Verrucaria, *id est*, Wertwort: whereas indeed, for other better effects and operations which it hath, it deserveth to have some denominations correspondent thereunto: for, a countrepoison it is against serpents and scorpions, if it be drunke with wine or honyed water, as *Apollophanes* and *Apollodorus* doe report in their writings. A liniment made of the leaves, cureth the rheums and distillations of the brain in children; which disease they call * Sitiasis. Likewise it helpeth contractions of sinewes and the drawing in of joynts, although the Patient be taken after the manner of the falling sickneſſe: and for such as be thus afflicted, a fomentation made with the decoction of this hearbe, is very holesome and comfortable: but if one drinke the colature thereof, it thrusteth forth the worms in the belly, and scoureth out the gravell in the kidnies. If Cumin be put thereto, it breaketh the stones engendred and confirmed there alreadie. Boiled it ought to be root and all; the which with the leaves and goats tallow being reduced into a liniment, is singular good for all kinds of gout.

The other kind which wee called Tricoccon, and is otherwise named Scorpiurion, hath not onely smaller leaves, but also they encline and bend downward to the ground. A seed it beareth resembling the figure of a Scorpions taile, whereupon it tooke that name. A liniment made therewith; is powerfull against all venomous beasts, and namely the perilous spiders Phalangia; but specially against the poison of scorpions. And in truth, looke who carrie this hearbe about them, shall not be stung. If a man make a circle or compasse upon the earth with the braunch of this hearb, a scorpion (as some say) being within the same, shall not have the power to get forth: nay, if the hearbe be laid upon a scorpion, or if with the same beeing wet a man besprinkle the said scorpion, it will surely die out of hand. It is said, that foure grains of the seed taken in drinke, doe cure the quartan; and three, the tertian: or if the very hearbe it selfe be laid under the Patients head, after it hath been thrice carried about the bed, it worketh the like effect. The seed is of power to stirre up carnall lust. Applied with honey, it discusseth biles rising in the emunctories. Yea and this Heliotropium for a certeintie, causeth werts to fall off by the very roots: as also it taketh away all excrescences in the fundament. It draweth downe by urine, the corrupt bloud in the reins and loins, lying cluttered about the ridge-bone, in case the seed bee either applied as a liniment, or sodden in the broth of a cocke or capon, and so supped off, or else with Beets and Lentils. As for the utmost rind of this hearbe, it is singular for to recover the fresh and native colour in places blacke and blew with stripes. The Magicians and Wise-men doe prescribe for the quartan and tertian agues, That the Patient should tie the hearbe Heliotropium, with three knots in a tertian, and with foure in a quartan, praying withall and making a vow, That hee would undoe those knots after hee were once cleare of the fever: but this he must doe before the hearb be taken out of the ground.

Another propertie as strange and miraculous, is reported of * Adiantum. In Summer it is greene: in Winter it withereth and decaieth not: it checketh all water, for being bespreint, dashed, and drenched quite therewith, yet it looketh as if it were drie: so great is the antipathie or contrarietie betweene them: whereupon the Greekes gave it that name. And otherwise a plant

* This is verefied of the Cichorie floure rather, which also regardeth the Sun.

* This is called *ardor capitis* by *Plinie* himself, and is an hote distemperature of the head.

* Maidenhair.

A it is fit for Vinet-workes and knots in a garden. Some call it Callitrichon, others Polytrichon, both which names were given it for the effect that it worketh. For it coloureth the haire [black.] And for this purpoſe it is ſodden in wine with the ſeed of Ach or Perſly: and a good quantitie of oile is put thereto, for to make the haire curled and to grow thicke: by which means it keepeth the hair from ſhedding & falling off. Two kinds ther be of it, the white and the black, which alſo is the ſhorter. The greater kind they call Polytrichon: the other, Trichomanes. Both of them have pretie fine branches ſhining with a black colour, and the leaves reſemble fearn; in which, the nether ſides underneath be rough, duskiſh, and brown: but all the leaves ſtand directly one againſt another in order, faſtened to the ſtalks by ſlender ſteles. No root at all theſe Capillar hearbs have: but they grow upon ſhadowie rockes and walls, daſhed and beaten upon with the water: but moſt of
B all they ſeeke after pits or holes of wels and ſprings, and ſtonie places whereat fountaines doe iſſue. And that is a ſtrange & marvellous thing: conſidering they are not wet with water, nor have any ſence or feeling thereof. They have a wonderfull facultie, and the blacke eſpecially, to break the ſtone, and to expell it out of the bodie. For which cauſe, rather than for growing upon ſtones and rockes, I beleeve verely it was by our countrymen called in Latin Saxifrage. To this purpoſe, as much as three fingers be able to plucke up, is ordinarily taken in wine. They provoke urine: and reſiſt the poyſon of ſerpents and venomous ſpiders. Being boiled in wine, they doe ſtay the flux of the bellie. A Chaplet made of them, allaieth the head-ach. And a liniment thereof is thought good to be applied againſt the ſting of the Scolopendres: but it muſt be often taken off and renewed, for feat the hearbe become over-drie and looſe all the vertue. In this wiſe is it to be uſed,
C where the haire is fallen away by ſome infirmitie. Theſe hearbes reſolve and diſcuſſe the kings evill: they diſpatch and rid away the ſkales or dandruffe in the viſage, and heale the ſkalls of the head. A decoction of theſe Maiden-haires, is ſingular good for thoſe who are ſhort winded: for the liver alſo, the ſpleene, the jaundiſe, and the dropſie. An ointment made with Maiden-haire and Wormewood, eaſeth the paines of the kidney: and in caſe of ſtrangurie, procureth eaſe and free paſſage of urine. They bring downe the after-birth in women, and their monthly tearmes. Howbeit, drinke them with vinegre or the juice of the blacke berrie bramble, they ſtanch bloud. A proper liniment is made thereof with oile Roſat, to annoint yong children which have the red gum and be all broken out: but firſt they would be bathed in wine. The leaves of Maiden-haire ſtamped with the urine of a man child under foureteene yeares of age, and not yet undergrown,
D together with the fome of ſalt-petre, is ſaid to keepe the bellies of women from wrinckles and rivels upon child-bearing, if they be annointed therewith. To conclude, men ſay, That Partridges and cockes of the game will fight more luſtily, in caſe this hearbe be entermingled with their meat. And the ſame alſo is very good for ſheepe to graſe upon about their folds.

Chap. xxii.

Of Picris, Theſium, Aſphodell, Alimus, Acanthus or Brankurſine, Elaphoboſcum, Scandix, Iaſione. Of Caucalis, Sium, Silybum, Scolymus or Limonium, Sonchus, Chondrillum or Chodrilles: and of Muſhromes.

E THe hearbe *Picris tooke the name (as heretofore we have ſaid) of the notable bitterneſſe which it hath. The leaves thereof be *round. Excellent good it is to take away werts. Theſium likewiſe commeth nothing behind for bitterneſſe: but it purgeth the bellie: for which purpoſe it muſt be ſtamped, ſtrained, and taken in water.

*A kind of Cichorie.

*So are none of our Cichories.

As touching the Aſphodell, it is one of the ſoveraign & moſt renowmed hearbs in the world. Some have given it the name Heroion. And *Heſiodus* hath written that it groweth in the woods. *Dionyſius* ſaith, That there is both male and female of it. Certaine it is, that the bulbous roots of the Aſphodell ſodden with husked Barley, is a ſingular reſtorative for thoſe bodies which are waſted with a conſumption, & eſpecially of the lungs. And bread made of them, wrought together with corne meale or floure into a dough, is moſt wholeſome for mans bodie. As for *Nicander*, he
F uſed to give either the ſtem which wee called Anthericon, or the ſeed, or elſe the Onion bulbous roots therof, in wine, to the quantitie of three drams, as a preſervative againſt ſerpents and ſcorpions: and to prevent the feare and daunger of theſe harmefull and peſtilent creatures, hee appointed the ſame to be laid under folks heads as they lay aſleepe. Vſually alſo is this hearb given againſt venomous fiſhes of the ſea, and the Scolopendres of the land. In Campaine, the ſhell-

ſnailes have a wonderfull ſpight againſt the maine ſtalke of this hearbe Aſphodell, for they ne- G
ver lin ſucking it, untill they have made it as drie as a kex. The leaves alſo are reduced into a li-
niment, for to be applied to envenomed wounds, occaſioned by ſuch ſerpents & hurtfull beaſts.
Likewiſe an ointment may bee made of the bulbous roots thereof, ſtamped together with Bar-
ley groats, for to annoint the ſinewes and joints. Good it is alſo to cut them into roundles, and
therewith together with vinegre, to rub ring-wormes and tettars. In like manner if they bee ap-
plied with water, they doe cleanſe putrified and rotten ulcers, yea, and the hote apoſtemations of
the paps and the cods. Being ſodden in wine lees, and ſo laid to the eyes, with a fine linnen rag
betweene, they cure the flux of humors thither, which cauſeth the eyes alwaies to water. Gene-
rally in any diſeaſe whatſoever, Phyſicians uſe the root of this hearbe boiled for the moſt part,
rather than otherwiſe. Likewiſe for the mor-males and uglie ſores in the legs, they uſe the pouder H
of them dried: as alſo for the fiſſures and chaps appearing in any part of the bodie. Now, the on-
ly fit and convenient ſeaſon to gather theſe roots, is in Autumne, at what time they bee moſt in
force. Being ſtamped raw, or ſodden, there is a juice preſſed foorth of them, which is ſoveraigne
with honey, for any pains of the bodie, whether it be the collicke, or ſeated in the muskles. And
the ſame being mixed with the drie root of Flower-de-lis, and a little quantitie of ſalt, is paſſing
good for thoſe that affect a ſweet ſmell, and would palliat the ranke ſavor of any part of the bodie.
Moreover, the leaves of the Aſphodell ſerve for all the former maladies, as alſo for the kings evil:
for red and flat biles, gout-roſat, ſauce-fleame, ale-pockes, and ſuch like ulcers in the face; if the
ſame be ſodden in wine, & therewith the greeved parts bathed. The aſhes of the root burnt, bring
haire againe upon the head where it was loſt and gone, and healeth up the chaps and rifts in the
feet. The juice of the root ſodden in oile, is good for kibed heeles, for burnes or skalds. To helpe I
the hardneſſe of hearing, the ſame juice is to be dropped into the ears: but to aſſuage the tooth-
ach, it muſt be inſtilled into the eare of the contrary ſide. The ſame root taken in drink moderat-
ly, is ſingular for to procure urine, to provoke womens months, & to mitigat the pain of the ſides
or pleuriſie. But given in wine to the weight of one dram, it cureth ruptures, convulſions or cramps
and coughs. The ſame being chewed, helpeth forward vomites, and cauſeth them to come with
more eaſe. The ſeed, if it be taken inwardly, troubleth and wringeth the belly. *Chryſermus* the Phy-
ſician uſed to boile the root in wine, and therewith cured the ſwelling kernils and inflammations
*The ſeed of a kind of Roſe-marie. behind the eares: likewiſe, with an addition of *Cachrys and wine, he healed the kings evill. Some
ſay, that if one take the Aſphodel root, and lay one part therof to thoſe ſwelling kernils called the
kings evill, & remove it upon the fourth day, letting the other part to hang in the ſmoke; the ſaid K
kernils will drie away, even as the root dooth in the chimnie. *Sophocles* (for the gout) uſed the root
both waies, as well raw as boiled. In caſe of humble-heels he applied it ſodden in oile: but to them
that were fallen into the jaundiſe or dropſie, he gave it in wine. Some writers have ſet down in their
books, that if either the members of generation be annointed with a liniment made therwith and
wine and hony together, or if the ſame be taken in drink, it will mightily provoke fleſhly luſt. *Xe-
nocrates* affirmeth, That a decoction of the root in vinegre taketh away the ring-wormes, tettars,
and running ſcabs. *Item*, If the root be boiled with Henbane and Tar, and therwith the armholes
and parts between the legs be well rubbed, it will rid away the ſtrong and ranke ſavor which com-
meth from thence: and if the head be firſt ſhaven, & afterwards rubbed with the ſaid root, the hair
comming afterwards will curle and frizle the better. *Simus* the Phyſician boileth it in wine, and ſo L
giveth it in drink, for to ſcoure away the ſtones of the kidnies. *Hippocrates* preſcribeth to give the
ſeed againſt the hardnes of the ſpleene and the flux proceeeding from thence. Furthermore, the
root being brought to a liniment, or the very juice thereof ſodden and uſed accordingly, healeth
the farſins, mange, and ſcab, in horſes, and reduceth the place to beare haire againe as faire as be-
fore. Aſphodell hath a propertie to chaſe away mice and rats: and if their holes bee ſtopped up
therewith, they die within.

Some are of opinion, that *Heſiodus* called Aſphodel, Alimon: which I take to be a meer untruth.
For ther is an hearb by it ſelfe called Alimon, about which writers have erred not a litle: for ſome
ſay, that it is a ſhrub growing thick, of a white colour, without any prick or thorn, bearing leaves M
like the Olive tree, but that they be ſofter: & this plant is entertained in the kitchin, there ſodden
and dreſſed for to be ſerved up as meat to the table. The root taken to the quantitie of one dram
in honied water, diſpatcheth the torments of the bellie: it cureth alſo convulſions and ruptures.
*Alyris rather, according to *Actius*. Others affirme, That *Alimon is a ſea-wort, of a ſalt and brackiſh taſt, whereof it had the name.

The

A The leaves be round, and yet after a ſort long withall: and the whole hearbe is highly commended for the pleaſant taſt, and good to be eaten. Moreover, there be two kinds of it: for the one is wild: the other is of a more civile & gentle nature. And both of them (by their ſaying) are good to be eaten with bread for the bloudie flix, even when the guts bee alreadie exulcerat: but with vinegre, for to comfort and helpe the ſtomacke. A liniment made of Alimon raw, is ſingular for old feſtered ulcers: and the ſame doth mitigat the ſymptomes that follow green wounds: as alſo aſſuageth the paines enſuing upon ſpraies and diſlocations of the foot: yea, and pacifieth the greeſe of the bladder. The wild of this kind hath ſmaller leaves; but more effectuall it is in the remedies beforeſaid: and withall, healath the ſcab as well in man as beaſt. Over and beſides, they do affirme, That if the bodie be rubbed with the root, the skin will be the fairer and more ſmooth: or
B if the teeth be ſo ſerved, they will be the whiter. Alſo that whoſoever hold the ſeed thereof under their tongues, they ſhall not be drie nor feele thirſt. This kind is likewiſe eaten at the bourd: and both of them are kept and preſerved condite. *Cratevas* hath made mention of a third ſort, which hath longer leaves than the reſt, and more rough in the hand: in ſmell reſembling the Cypreſſe tree, who ſaith, That it delighteth principally to grow under the Yvie tree: which if it be taken to the weight of three oboli in a ſextar of water, helpeth thoſe that have their heads and bodies drawne far backe, and ſuch as be troubled with the contraction and ſhrinking of ſinewes.

As touching Acanthus or Brankurſine: an hearbe it is cheriſhed much in gardens, proper for vinets and ſtorie workes, bearing upright and long leaves, wherewith beds-ſides and borders of quarters in gardens are beautified and decked. Two kinds there be of it: one with prickie leaves in
C manner of thiſtles, and the ſame jagged, which is the leſſe and lower of the twaine: but the greater, which ſome in Greeke call Pæderos, others Melamphyllon, is ſmooth leaved. The leaves of this Brankurſine being applied, are wonderous good for burns and diſlocations. Alſo being ſodden with meat, and eſpecially with Piſane or husked Barley, it is ſingular for thoſe who are burſten, troubled with the crampe, and ſubject to the conſumption of the lungs. Alſo if they be ſtamped and reduced into the forme of a liniment, and laid too hot, they cure the gouts proceeding from an hote cauſe.

The hearbe *Bupleuron, is reckoned by the Greeke writers in the number of worts that grow of themſelves. A ſtem it hath of a cubit in height: many leaves, & thoſe growing long in a ſpoke-tuft, or rundle in the head, in manner of Dill; highly commended by *Hippocrates* for good meat:
D but *Glycon* and *Nicander* praiſe it as much for the uſe thereof in Phyſicke. And in very truth the ſeed is powerfull againſt ſerpents. The leaves alſo, or the very juice, incorporat with wine into the forme of a liniment, they employ for to bring downe the after-birth of women newly delivered: as alſo the leaves, with ſalt and wine, are uſed by way of cataplaſme, for to diſſolve the ſwellings called the kings evill. As for the root, it is uſually given in wine againſt venomous ſerpents, and to provoke urine.

*Bupreſtis is an hearbe, about which the Greek writers have ſhewed themſelves, namely, how inconſtant and light of credit they be; in that they have ſo highly praiſed it to be a ſpeciall holeſome meat, yea, and a ſingular remedie againſt poyſons. For the very name doth ſhew evidently, that it is a poyſon it ſelfe, of Kine and Oxen at leaſtwiſe. And they themſelves doe confeſſe, That
E if ſuch cattell taſt of *Bupreſtis, it will make them enraged, and fall a gadding untill they burſt in ſunder. And therefore I will not ſpeake any more of this hearbe: for there is no reaſon that may induce me to deſcribe theſe venomous weeds, among thoſe that ſerve for the greene Guirlands aforeſaid made of graſſe: unleſſe haply it bee this, That ſome one or other would ſeeke after this hearbe to weare it in a Chaplet for luſt ſake: *which indeed (they ſay) it will provoke no leſſe that way, than if it were taken in drinke.

*Elaphoboſcon is an hearbe growing up with a maine ſtem, after the manner of Fenellgeant: the ſame is full of knots and joints, as thicke as a mans finger. The ſeed is made after the faſhion of Berries hanging downe in manner of Sili or Siler-mountaine: howbeit, nothing bitter they are, and the leaves reſemble thoſe of Aliſanders. This hearbe is taken for a commendable meat.
F And in truth is kept alſo and preſerved a long time confected and condite, for a ſingular remedy to procure urine, to allay the paine of the ſides in the pleuriſie, to heale ruptures, to cure convulſions and cramps, to diſcuſſe ventoſities, to aſſuage the dolorous torments of the collicke: yea, & as a very countrepoyſon againſt the ſting of ſerpents, & all other creatures armed with ſtings: for the report goeth, That Stags and Hinds by feeding thereupon, withſtand the venome of ſerpents.

*Some name it Hares-eare.

**Heſych. Βύπρηστις ὄλυς. βύπρηστις ἔντομον ἰὸν ἔχον.*

* But they meane the venomous Inſect *βύπρηστις.*

*In truth the flies Bupreſtes, which ſome take to be Cantharides, are thought to have ſome operation in that kind.

*Which ſome take for a kind of wild *Angelica* or *Gratiæ dei.*

pents. The root alſo reduced into a liniment with Sal-nitrum, put thereto and incorporat toge- G
ther, cureth old ſores called Fiſtulaes. But the ſaid root ought to bee dried firſt for thoſe purpo-
ſes, to the end that it ſhould not be full of the owne juice and moiſture: and yet this humor dul-
leth not the vertue thereof, nor maketh it leſſe effectuall againſt the ſting of ſerpents.

Pecten veneris, wild Chervile, or ſheepheards needle.

Touching the hearbe *Scandix, the Greekes have raunged it alſo among the wild worts and pothearbes good for to be eaten, according to *Opion* and *Eraſiſtratus*. The ſame being ſodden, knitteth the bellie and ſtoppeth a laske. The ſeed taken with vinegre, preſently ſtaieth the yox or hicquet: it provoketh urine, and ſerveth well in a liniment to heale up burnes. The juice of it be-
ing boiled to a juleb, is good for the ſtomack, liver, kidneies, and bladder. This is the hearb which *Ariſtophanes* the Comædian twitted the Tragicall Poet *Euripides* by, objecting unto him meri-
ly by way of a ſcoffe, That his mother (who was a gardener) uſed to ſit in the market and ſell never H
a good wort or pothearbe indeed, but made her markets onely of Scandix. And verely, I would
Our Chervile. ſay that *Anthriſcus were the ſame hearbe, if it had ſmaller, tenderer, and ſweeter leaves: This pe-
culiar praiſe & commendable propertie it hath, that if the bodie be overlaied and wearied with the uſe of women, it reſtoreth the ſpirits, and refreſheth them again: yea, & ſuch as be well ſtept in years and begin to droupe, it maketh luſtie and able to perform the act of generation youth-
fully. It ſtaieth the flux of the whites in women.

A kind of ſmooth Bind-weed.

Moreover, *Iaſione is counted alſo a wild wort, comming up of it ſelfe and good to be eaten. This hearbe creepeth by the ground: full of milke it is, and beareth a white flower, which ſome call Concilium. The like name and commendation there goeth of this hearbe for ſtirring unto letcherie. Being taken raw with meat in a vinegre ſauce, it breedeth plentie of milke in women. A I
ſingular reſtorative it is for them that feele themſelves wearing and decaied by a conſumption. A liniment made therewith, and applied to the head of young infants, cauſeth haire to come up thicke: and by ſhutting the pores of the skin more cloſe, it is a meanes to retaine the haire ſtill, that it ſhed not eaſily.

Baſtard Perſly.

As for *Caucalis, an hearbe like to Fennell, but that it hath a ſhort ſtalke and a white flower: it is good alſo to be eaten, and is beſides counted a cordiall. A drinke likewiſe is made of the juice thereof, paſſing comfortable to the ſtomacke: of power to provoke urine, to expell gravell and ſtone, and to ſtay the itching within the bladder: It doth ſubtiliat the groſſe and tough fleame, which cauſeth obſtructions in the ſpleene, liver, and kidneies. The ſeed being taken inwardly, hel-
peth forward the monthly ſickneſſe of women when it ſtaieth upon them, and drieth up the cho- K
lericke humors that flow after child-birth, or the after-burden. It is given alſo to men, for the ſpil-
ling of naturall ſeed, or the running of the reins. *Chryſippus* is of opinion, That it is ſingular good to helpe women for to conceive, if they be deſirous of children. But the manner is to drinke it in wine next the heart faſting. And as *Petricus* the Poet hath delivered in verſe, a liniment of this hearbe is ſingular againſt the poyſons of venomous ſea-beaſts.

A kind of water-Creſſes or Laver.

Among theſe hearbes is reckoned *Sion, a plant growing in waters of it ſelfe, with leaves like Perſely or Smallach, but that they be larger, fatter, and of a deeper blackiſh green: it beareth ſeed plentifully, and in taſt reſembleth water-creſſes. It is thought to be excellent good for thoſe that cannot make water; for the diſeaſes of the reins, and paine in the ſpleen; yea, & for women whoſe monthly tearmes be ſuppreſſed: whether the ſubſtance thereof bee taken as meat, or the juice of L
the hearbe decocted, or the ſeed drunk in wine to the weight of two drams. It breaketh the ſtones engendred within the bodie: and notwithſtanding it groweth in water, yet it dooth evacuat thoſe aquoſities and waterie humors which engender the ſame. Being clyſterized, it helpeth thoſe that have the bloudie flix. If women annoint their faces with a liniment made of it overnight, it dooth embelliſh their skin at one inſtant and with one dreſſing: yea, it taketh away the pimples and ſpots that disfigure the face, in manner of Lentils. This ointment is held alſo to be good for the farſins and ſuch ſores, in horſes and ſuch like beaſts: and to mitigat the greevous paines and trou-
ble of any ruptures.

As concerning Silybus, an hearbe like unto the white Chamæleon, and as full of thornes: it groweth abundantly in Cilicia, Syria, and Phœnice: and yet in theſe countries they make not ſo M
much account of it as to beſtow the dreſſing of it, it asketh ſo much adoe in the kitchin before it be in caſe to be ſerved up into the hall. And for Phyſicke, there is no goodneſſe in it at all.

Some take theſe for our Artichokes.

The plant *Scolymus is uſed alſo much to bee eaten in the Eaſt parts, where they call it by another name Limonia. It never exceedeth a cubite in height: the leaves bee creſted, the root

blacke,

A blacke, but yet ſweet. *Eratoſthenes* commendeth it as a principall diſh for a poore mans table: and it is ſaid that it hath a ſpeciall vertue to provoke urine: and with vinegre if it be applied, to cure the foule tettars called Lichenes, and the leproſie. Alſo, by the teſtimonie of *Heſiodus* and *Alcæus*, if it be taken in wine, it inciteth to wantonneſſe and fleſhly pleaſures. Theſe Poets doe write, That when this hearbe doth flouriſh and is at the beſt, then graſhoppers chant loudeſt and ſing moſt thrill: and as women at ſuch a time be moſt deſirous of mens companie and hoteſt in luſt, ſo contrariwiſe men are moſt loth to turne unto them, and leaſt able to content their appetite: as if Nature to ſatisfie the pleaſure of theſe good wives, had provided againſt that faint ſeaſon, the help of the Artichoke, as a viand moſt powerfull at this time to ſet their husbands in a heat, and to enable them to that buſineſſe. Moreover, an ounce of the root cleanſed from the pith, ſodden
B to the thirds in three hemines of the beſt Falerne wine, and either taken in drinke upon an empty ſtomack, preſently after that one hath ſweat, and is new come forth of the Baine: or els to the quantitie of one cyath immediatly after every meale, doth correct and take away the ſtinke and ranke ſmell of the arme-pits. And a ſtrange thing it is, that *Xenocrates* affirmeth upon his own experience, and promiſeth, That this decoction is of ſuch efficacie, that it cauſeth the ſaid ſtrong ſent to paſſe away by the urine.

Moreover, the *Sowthiſtle is an hearbe for to be eaten: for we read in the Poet *Callimachus*; That the poore old woman *Hecale*, at what time as prince *Theſeus* fortuned upon neceſſitie to take his repaſt in her ſimple cottage, made him a feaſt, and ſet before him a principall diſh of Sowthiſtles. Two kinds there bee of them, the white, and the blacke: both, like unto Lectuce, but
C that they are full of prickes. They run up into a ſtalke of a cubite in height, the ſame is cornered and hollow within; but breake it, and you ſhall ſee it run out with milke plentifully. The white, which hath that bright colour of the milke within it, is thought to bee as good as Lectuces, for thoſe that be ſtreightwinded, & cannot take their breath but upright. *Eraſiſtratus* ſheweth plainely, That if it bee eaten, it expelleth gravell by urine: and chewed onely, it correcteth the ſtinking ſavor of the mouth, and cauſeth one to have a ſweet breath. The juice thereof drawn to the meaſure of three cyaths, made hot in white wine and oile, and ſo taken, helpeth women in labor, that they may bee ſoone delivered: but preſently after they have drunke it, they ought to ſtir their bodies and walke up and downe their chamber. Alſo it is uſed to be ſodden in broth, and ſo ſupped up. The very ſtalke thereof being boiled, maketh milch nources to have good ſtore of milke, and
D the children at their breaſt to be better coloured. But moſt excellent it is for ſuch nources as feele their milke to cruddle in their breaſts. The juice therof dropped into the eares, doth them much good: and a meaſure of one cyath drunke hote, is as good for the ſtrangurie. But in the fretting and gnawing of the ſtomacke, it would be taken with Cucumber ſeed and Pine-nut kernils. Applied in forme of a liniment, it cureth the apoſtemations in the fundament. A drink is made therof, which is a countrepoyſon againſt ſerpents and ſcorpions: but then the root alſo muſt be laid outwardly unto the ſore place. The ſame root boiled with oile within the pill of a pomgranat, is a good remedie for the paines and maladies of the eares. Note, that all theſe vertues muſt be underſtood of the white Sowthiſtle. And *Cleemporus* doth accord hereunto as touching the white; but he alloweth in no wiſe to eat of the blacke, for he is of opinion, that it breedeth diſeaſes. *Aga-*
E *thocles* alſo preſcribeth the juice of the white Sowthiſtle to them who have drunk Buls bloud, and ſuſpect themſelves poyſoned therewith. Howbeit, they bee all agreed, that the black is refrigerative: in which regard it ought to be applied outwardly with Barley groats. *Zenon* declareth, That the root of the white Sowthiſtle, cureth the ſtrangurie.

As for *Chondrillon or Chondrille, it hath leaves like unto Endive or Cichorie leaves gnawed or eaten round about: a ſtem not a foot high, and the ſame full of a bitter juice: a root like unto *a Beane, and otherwhile there be many of them together. This hearbe putteth forth cloſe to the ground a certaine kind of gum like Maſticke, ſwelling out to the bigneſſe of a Bean; which being applied to the naturall parts of women, is ſaid to draw downe their monthly courſes. The ſame hearbe being ſtamped root and all together, and digeſted into troſches, is thought to bee
F ſingular good againſt ſerpents. And a probable reaſon hereof is collected, becauſe the field mice and rats when they are ſtung by ſerpents, have recourſe to this hearbe, and eat thereof. The juice drawne out of this hearbe after it is ſodden in wine, bindeth the bellie. The ſame is ſingular good to rectifie, couch and lay even the diſorderly haires of the eye-lids, as effectually as the beſt gum in the world. *Dorotheus* the Poet hath delivered in his verſes, That it is good for the ſtomack, and helpeth

*Sonchus.

*Gum Succhorie.

* *Dioſc.* πάχιον, i. full and freſh: but it ſeemeth that *Pliny* read it ὑγρόν.

helpeth digeſtion. Some hold opinion, That it is naught for women and hurtfull to the eyes, alſo G
that it is contrarie to the ſeed of man and doth hinder generation.

Among all thoſe things which are eaten with daunger, I take that Muſhromes may juſtly bee raunged in the firſt and principall place. True it is, that they have a moſt pleaſant and delicat taſt, but diſcredited much they are and brought into an ill name, by occaſion of the poyſon which *Agrippina* the Empreſſe conveighed unto her husband *Tiberius Claudius* the Emperor, by their meanes: a daungerous preſident given for the like practiſe afterwards. And verely by that fact of hers, ſhe ſet on foot another poyſon, to the miſcheefe of the whole world and her own bane eſpecially (even her owne ſonne *Nero*, the Emperor, that wicked monſter.) The venomous qualitie of ſome of theſe Muſhromes, may bee ſoone knowne by their weake redneſſe, their mouldie hew ſo unpleaſant to ſee to, their leaden and wan colour within-foorth, their chamfred ſtreakes full of H
chinkes and chaps, and finally, their edges round about pale and yellow. For, others there be that have none of all theſe markes: but are drie, and carie certaine white ſpots like to drops or grains of Sal-nitre, putting foorth in the top out of their tunicles. And in truth, before that the Muſhrome is formed, the earth bringeth forth a certain pellicle or coat firſt, called in Latine Volva; for this purpoſe, that the Muſhrome ſhould lie in it: and then afterwards ſhee engendreth it encloſed within, much like as the yolke of an egg couched within the white. And ſo long as the Muſhrome is young & not come forth, but lieth as a babe within, the ſaid core or tunicle is as good meat as the Muſhrome it ſelfe: but ſo ſoon as the Muſhrome is formed, this membrane breaketh, and incontinently the bodie or ſubſtance thereof is ſpent in the ſtele or foot that beareth it up: and ſeldome ſhall you ſee two Muſhromes upon one of theſe ſteles or feet. Moreover, theſe Muſhromes take their firſt originall and beginning of a ſlimie mud, and the humor of the earth that I
is in the way of corruption: or els of ſome root of a tree, and ſuch for the moſt part as bear Maſt. It ſeemeth at the firſt, as if it were a kind of glutinous fome or froth: then it groweth to the ſubſtance of a pellicle or skin, and ſoone after ſheweth the Muſhrome indeed, bred, formed, and conſummat within, as is beforeſaid. And verely all ſuch are pernicious and utterly to be rejected, neer unto which when they come new out of the ground, there lay either a greive-ſtud or leg harneis-naile, or ſome ruſtie yron, or ſo much as an old rotten clout: for looke what naughtineſſe ſoever was in any of them, the ſame they draw and convert into venome and poyſon. But none are able to diſcerne theſe huttfull Muſhromes from others, how curious and circumſpect ſoever they bee, ſave onely the peaſants of the country where they grow, and ſuch as have the gathering of them. And here is not all the miſcheefe that lieth in them: For dangerous they be otherwiſe, and meet K
with more meanes to make them deadly, namely, if a ſerpents hole or neſt be neare by: or if at their firſt diſcoverie and comming forth, a ſerpent chance to breath and blow upon them: for ſo prepared they be and diſpoſed as a fit ſubject, to enter, that preſently they will catch and entertain any poyſon. And therefore on any hand we muſt not be bold & luſtie with them before the time that ſerpents be retired into the ground, and there taken up their harbor. Which is an eaſie matter to know, by the tokens of ſo many hearbes, trees, & ſhrubs, which from the time that they firſt come abroad above ground, untill they have taken up their Winter lodging againe, looke alwaies freſh and greene: and principally by the leaves of the Aſh, alone, if there were no more trees: for Aſhes neither bud and ſpring forth, but after that ſerpents come abroad; nor ſhed and L
fall away, before they be gone into the ground againe. In ſum, this would bee noted, That Muſhromes be up and down, come and gone, alwaies in a ſeven-night ſpace. Thus much of the Muſhromes named in Latine Boleti.

Chap. xxiii.

Of other Muſhromes or Tad-ſtoles called Fungi. Of Silphium, and Laſer.

AS touching thoſe excreſſences in manner of Muſhromes, which be named Fungi, they are by nature more dull and ſlow. And albeit there bee many kinds of them, yet they all take their beginning of nothing els but the ſlimie humor of trees. The ſafeſt and leaſt daunge- M
rous be thoſe, which have a red calloſitie or outward skin, and the ſame not of ſo weake a red, as that of the Muſhromes called Boleti. Next to them in goodneſſe are the white, and ſuch as having a white foot alſo, beare a head much reſembling the Flamins turbant or mitre, with a tuffet or creſt in the crowne. As for the third ſort which be called Suilli, as one would ſay, Swine-Muſh-

romes

A roms or Puffs, they are of all others most perilous, and have the best warrant to poison folke. It is not long since that in one place there died thereof, all that were of one houshold; and in another, as many as met at a feast and did eat thereof at the same bourd. Thus *Annæus Serenus*, captaine of the Emperour *Nero* his guard, came by his death, with divers coronels and centurions, at one dinner. And I woonder much, what pleasure men should take thus to venture upon so
1 doubtfull and dangerous a meat. Some have put a difference of these mushroms, according to the severall trees from which they seeme to spring, & have made choice of those that come from the Fig-tree, the * Birch, and such as beare gum. For mine own part, as I have said before, I hold those good that the Beech, Oke, and Cypresse trees do yeeld. But what assurance can a man have hereof, from their mouths who sit in the market to sell them? for all the sort of those Puffs and
B Toadstools looke with a leaden hew and wan colour. Howbeit, the nearer that a Mushrom or Toadstoole commeth to the colour of a fig hanging upon the tree, the lesse presumption there is that it is venomous.

Touching the remedies for to help those who suspect they have eaten these dangerous mushroms, I have said somewhat alreadie, and will say more hereafter. Meane while this would be noted, that as perilous as they be, yet some goodnesse there is in them, and divers medicines they doe yeeld. First and foremost, *Glaucias* thinketh and affirmeth, That the mushroms Boleti be good for the stomacke. As for the swine mushroms, named in Latine Suilli, they are hanged up to drie enfiled upon a rush running through them, as we may see in those which come out of Bithynia. And these are supposed to be singular for those fluxes and catarrhes which take a course
C to the belly and breed fluxes, called by the Greeks Rheumatisms: these cure the excrescenses of the flesh, which rise in the fundament; for they eat them down, and in tract of time consume them quite: likewise they are good to take away the pimples and freckles which appeare upon the skin like to Lentils, yea and the deformities and spots in womens faces which disfigure their beautie. These mushroms be * washed as lead, for to enter into collyries and eye salves: and a liniment is made thereof, which beeing applied with water, cleanseth filthie sores and ulcers, cureth the skalls which breake out in the head, and healeth the wounds occasioned by the biting of dogs.

And now for that our fine-mouthed and daintie wantons who set such store by their tooth, take so great delight to dresse this onely dish with their owne hands, that they may feed therupon in conceit and cogitation all the while they bee handling and preparing the same, furnished in
D this their businesse with their fine knives and rasors of amber, and other vessels of silver plate about them: I for my part also am content to frame and accommodat my selfe to their humorous fansie, and will shew unto them in generall, certain observations and rules how to order and use them, that they may be eaten with securitie. Marke then those mushroms, which in the seething proove hard and tough, such be all of them hurtfull: Lesse daungerous they be, if some sal-nitre be put unto them whiles they be a boiling over the fire; provided alwaies, that they be fully sodden before they be taken off. Also, a man may be more bold to eat those which be sodden together with flesh meat, or with the tailes or steles of peares. The eating also of peares, immediatly after one hath fed upon mushroms, doth kill or dull all the malice that they may have. Also vi-
E negre is of a contrarie nature unto them, and doth extinguish or mortifie their venomous qualitie. To conclude, all these mushroms do come up and are engendred in raine. Semblably, good showres doe breed Silphium.

This Silphium came at the first from Cyrenæ, (as I have before written) but now adaies, since time that all the Cyrenaick Silphium is destroyed and gone (as hath been said) the greatest store thereof is brought out of Syria: howbeit so good it is not as that which Parthia yeeldeth, although it be better than that which the merchants bring over with them out of Media. This * Silphium is of great use in Physicke; for the leaves are sodden in white odoriferous wine: of which decoction, there is made a drinke for to cleanse and purifie the matrice, and to expell the dead infants therein; so it be taken to the measure of one Acetabulum, immediatly after the woman hath ben in the stouve, and there swet. The root is singular for to cleare the windpipes, and to take away
F all the asperitie & roughnesse in those parts: and being applied in forme of a liniment, it helpeth impostumat inflammations proceeding from the rankenesse and ebullition of bloud: and yet as many as take it at the mouth and eat thereof, find that it is hard of digestion; for it breedeth ventosities and causeth much belching. Hurtfull also it is and contrarie to the free passage of urine. A liniment made thereof, together with wine and oile, is a most familiar and agreeable medicine

* *Betula*, non *Ferula*.

* *Lavantur* us *plumbum*, some read *Linuntur ad plumbum*: *id est*, A liniment is made of them for lead-shotten eyes, &c. *vide cap.* 13. *lib.* 25.

* or *Laserpitii*.

for the blacke and blew marks remaining after ſtripes: but if the ſame with ſome addition of wax, G
be reduced into a cerot, it healeth the Kings evill. The piles or werts growing in the fundement, with a ſuffumigation of Silphium oftentimes uſed, will fall off.

As for the liquor Laſer, iſſuing from Silphium, (in that manner as I have ſhewed) it is holden for one of the moſt ſingular gifts that Nature hath beſtowed upon the world, and entreth into many excellent confections and compoſitions. Of it ſelfe alone, it reduceth thoſe to their naturall health, who are ſtorven and benummed with extreame cold. Taken in drinke, it allaieth the accidents and griefes of the nerves. It is both given to women in wine, and applied alſo in ſoft locks of wooll to their naturall parts, for to bring downe their menſtruall purgation. If it be mixed and incorporat with wax, it draweth and fetcheth out by the roots, the agnels or corns in the feet, if ſo be they be ſcarified round about before with the launcet. Being diſſolved in ſome convenient liquor and taken to the quantitie of a cich peaſe, it provoketh urine. *Andreas* the Phyſician H
doth aſſure and warrant us, That if it be taken in greater quantitie, it breedeth no windineſſe in the ſtomacke, but helpeth digeſtion mightily both in women and alſo in old men: Who ſaith moreover, that it is better and more holeſome in winter than in ſummer, and for thoſe eſpecially who drinke nothing els but water: onely they muſt looke to this and take heed, that there be no exulceration within their bodie. A great reſtorative it is with meat, and quickly ſetteth them on foot, who have lien long and been brought low by ſickneſſe: for Laſer, if it be applied in due time, is as good as a potentiall * cauterie to raiſe a bliſter: but better it is for them who are acquainted with it, than for thoſe who have not ben uſed to it. Outwardly applied, no man maketh doubt but it is of ſingular operation, and worketh many effects. Taken in drinke, it doth extin- I
guiſh the venome left in the bodie, either by poiſoned dart, or ſerpents ſting: and if the wounds bee annointed with the ſame, diſſolved in water, it is the better: but particularly for the pricks of ſcorpions, it would be applyed with oile. Alſo in caſe that ulcers will not grow to any maturation, nor yeeld from them concocted matter; a pulteſſe made of Laſer, togither with barley flowre or figs, is a ſingular digeſtive. Being laid too with Rue, or hony, or by it ſelfe alone (ſo that the place be annointed over it with ſome viſcous gum to keepe it too that it run not off) it is excellent for the carbuncle, and the biting of dogs. If it be ſodden in vinegre with the rind or pill of a pomegranat, it is paſſing good for the excreſcences ariſing about the tiwill, if the place be bathed with that decoction. Being incorporat with Sal-nitre, and well wrought withall beforehand, and ſo applied, it taketh away the hard horns and dead corns ariſing in the feet, which commonly bee K
called in Latine Morticini. Tempered with wine and ſaffron or pepper, or if it be but with mice dung and vinegre, it is a good incarnative in ulcers: and an excellent drawer to the outward parts for to fill up the skin and make a bodie fat. A good fomentation there is made of it & wine, for to bath kibed heels: for which purpoſe, it is boiled in oyle and ſo applyed. In like manner, it ſerveth to ſoften hard calloſities in any place whatſoever: and for the foreſaid corns of the feet eſpecially, if they be ſcarrified and ſcraped before, it is of great efficacie. Singular it is againſt unholeſome waters, peſtilent tracts, and contagious aires; as in times ſuſpected of infection. Soveraigne it is for the cough, the fall of the Vvula, and an old jaundiſe or overflowing of the gall: for the dropſie alſo & horſeneſſe of the throat; for preſently it ſcoureth the pipes, cleereth the voice againe, and maketh it audible. If it be infuſed and diſſolved in water and vinegre, and ſo applyed L
with a ſpunge, it aſſuageth the gout. Taken in a broth or thin ſupping, it is good for the pleureſie, eſpecially if the Patient purpoſe to drinke wine after it. Being covered all over with wax to the quantitie of one cich peaſe, it is given very well in caſe of contractions and ſhrinking of ſinews, and namely to ſuch as carrie their heads backward perforce, by occaſion of ſome crick or cramp. For the ſquinance, it is good to gargarize therwith. Semblably it is given with leeks and vinegre, to thoſe that wheaze in their cheſt, and be ſhort winded, & have had an old cough ſticking long by them: likewiſe with vinegre alone, to ſuch as have ſupped off and drunke quailed milke, which is cluttered within their ſtomacke. Taken in wine, it is ſingular for the faintings about the heart; as alſo for colliquations and ſuch as are falne away and far gone in a conſumption, & thoſe that be taken with the falling ſickneſſe: but in honyed water, it hath a ſpeciall operation reſpective to M
the palſie, or reſolution of the tongue. With ſodden honey and Laſer together, there is made a liniment, very proper to annoint the region of the hucklebone, where the Sciatica is ſeated; and the ſmall of the backe, to allay the paine of the loins. I would not give counſell (as many writers doe preſcribe) for to put it in the concavitie or hole of a rotten tooth, and ſo to ſtop up the place cloſe

* He meaneth by *Cauterium κατακχαστικὸν, medicamente μετασυλκεστικὸν, or μεταποεστοτικὸν*, which draweth humors and the blond to the able and outward parts: a neceſſarie courſe to be taken in Atrophia, & namely after long diſeaſes, that the bodie may be equally nouriſhed.

A cloſe with wax, fot feare of that which might enſue therupon: for I have ſeene the fearfull ſequele of that experiment, in a man, who upon the taking of that medecine, threw himſelfe headlong from an high loft and brake his necke; ſuch intollerable pains he ſuſteined of the toothach: and no marveile, for doe but annoint the muffle or noſe of a bull therewith, it will ſet him on a fire and make him horne-mad: and being mingled with wine, if ſerpents (as they are moſt greedie of wine) chaunce to lap or licke thereof, it will cauſe them to burſt. And therefore I would not adviſe any to be annointed with it and honey of Athens incorporat togither; howſoever there be Phyſicians who ſet downe ſuch a receit. Certes, if I ſhould take in hand to particularize of the vertues that Laſer hath, beeing mingled with other matter in confections, I ſhould never make an end: But my purpoſe is to deale with ſimples only, wherein Natures worke is moſt ap-
B parent and evident to be ſeene; whereas in compoſitions, we go altogither by conjectures which many times deceive us: neither can a man bee aſſured of their operation; for who is able to obſerve the juſt proportion in thoſe mixtures, either of the contrarieties and repugnances, or the concord and agreement of the ingredients in Nature? But of this point I will write more at large hereafter.

Chap. xxiiii.

Of the nature and properties of Honey. Of honyed water or Mead called Hydromel. How it commeth to paſſe that the maxners and behaviours of men be altered by meat and viands. Of honyed wine named Melitites, and of Wax. Alſo,
C *againſt the abuſe in compoſition of medicines.*

HOney, were it not ſo common as it is, and every where to be had, would be as highly eſteemed and of as great price as Laſer. As for this drug, Nature hath framed and made it immediatly her owne ſelfe; but for the getting and working of Honey, ſhee hath created a living creature of purpoſe, as wee have alreadie ſaid: by means whereof, wee have this cœleſtiall liquor, which ſerveth for an infinit number of uſes, conſidering how often it entreth into mixtures and compoſitions. And firſt to ſpeake of that cereous ſubſtance Propolis, which (as it hath been ſhewed alreadie) offereth it ſelfe firſt to bee ſeene at the very entrie of the Bee-hive, theſe vertues medicinable it hath; namely, to draw foorth all pricks, thorns, and what offenſive thing
D ſoever ſticketh within the fleſh of a bodie; to diſſolve and diſſipat all tumours and ſwelling bunches, to concoct and mollifie any hardneſſe; to aſſuage the pains of ſinews; and finally, to incarnat, heale up, and skin any deſperat ulcers.

As touching Honey it ſelfe, of this nature verely it is, That it will ſuffer no dead bodies to putrifie; notwithſtanding it be of a ſweet and pleaſant taſt, far from any ægreneſſe, and contrarie to the nature of ſalt: for the throat, the kernels of each ſide thereof called the Tonſils or Amygdals; for the ſquinancie, and all the accidents befalling to the mouth; as alſo for the drineſſe of the tongue through extremitie of heat in fevers, it is the moſt ſoveraigne thing in the world. Honey boiled, is ſingular for the inflammations of the lungs, and for the pleureſie: alſo it cureth the wounds inflicted by the ſting or teeth of Serpents; and helpeth thoſe who have eaten venomous
E muſhroms. Being taken in dulcet or honeyed wine, it cureth thoſe that lie of a palſie: although indeed the ſaid honeyed wine alone hath many gifts and properties by it ſelfe. Honey, togither with oyle of Roſes, dropped into the ears, cureth their ſtinging and paine. Good it is alſo for to kill lice and ſuch like vermin in the head, and to rid away nits: where, note by the way, that if honey be deſpumed, that is to ſay, skummed and clarified, it is evermore the better for any uſe. Howbeit, the ſtomacke it puffeth up and maketh to ſwell with ventoſities: it engendreth and encreaſeth cholerique humours, and taketh away appetite to meat: yea and ſome are of opinion, That being uſed ſimply alone, and not compounded with other things, it is hurtfull to the eyes: and yet others give counſell, to touch and annoint the corners of the eyes therewith, when they be
F exulcerat. Touching the materiall cauſe whereof honey is engendred, the manner how, the divers ſorts, the countries where it is made, the price alſo and value, with the ſundry proofes and trials thereof, I have written alreadie once in my treatiſe of Bees; and a ſecond time in my diſcourſe of the nature of Floures: for ſo the order and courſe of this my worke forced me to treat diſtinctly of thoſe matters; which, they that be deſirous to know exactly the nature of ſimples, may put togither and mingle againe at their pleaſures. By the ſame reaſon alſo, ſince we are en-

tred into the vertues and operations of Honey, I muſt of neceſſitie handle and declare the quali- G
ties of Hydromel or Honyed-water, ſo neare a dependant thereunto.

Of which there be two kinds: The one is freſh and new made in haſt upon occaſion, and preſently uſed: the other is kept and preſerved. As touching the former Hydromel, if it be made as it ſhould be, of deſpumed and clarified honey, it is of ſingular uſe in that exquiſit and ſparie diet fit for ſicke perſons, and namely in meats of light digeſtion; ſuch as is a thin gruell made of naked frumentie waſhed in many waters: alſo to be joyned with reſtoratives, for to recover the Patients ſtrength much enfeebled. Moreover, good it is for the mouth and the ſtomacke, to mitigat the fretting humors ſetled and bedded therein; and to coole the extremitie of heat: for I find in good authors, that to eaſe and mollifie the belly, it is better to be given cold than otherwiſe: as alſo that it is a proper and convenient drinke for thoſe who chill and quake for cold: likewiſe for H
ſuch as be heartleſſe and have ſmall or no courage at all, whom thoſe writers call *Micropſychos.

*Some read μικρόσφυκτους out of *Dioſcor.* having a faint and weake pulſe.

Moreover, there is a reaſon rendred, full of infinit ſubtilitie, and the ſame fathered firſt upon *Cato*, Why the ſame things ſeem not alwaies bitter or ſweet alike in every mans taſt? for he ſaith, that this diverſitie proceedeth from thoſe little motes or *bodies that goe to the making of all things: whiles ſome of them be ſmooth, others rough & rugged; ſome cornered, others round: in ſum, according as they be more or leſſe reſpective and agreeable to the nature of each man. This is the cauſe, that thoſe perſons who are over-wearied or exceeding thirſtie, be more cholerique and prone to anger. Good reaſon therfore, that ſuch aſperitie of the ſpirit, or rather indeed of the vitall breath, ſhould be dulced and appeaſed, by the uſe of ſome ſweet and pleaſant liquor, which may lenifie the paſſage and mollifie the conduits of the ſaid ſpirit, that they doe not cut, I
race, and interrupt it going in and out in drawing or delivering the wind. And in very truth, everie man may find by experience in his owne ſelfe, how meat and drinke doth moderat & appeaſe anger, ſorrow, heavineſſe, and any paſſion or perturbation of the mind whatſoever. And therefore thoſe things would bee obſerved, which make not onely to the nouriſhment and health of the bodie, but alſo ſerve for to rectifie and reforme the manners and demeanour of the mind.

*Some read μικρόσφυκτους out of *Dioſcor.* having a faint and weake pulſe.
* *Corpuſculis rerum.*

Now to returne againe unto our Hydromel or Honyed-water, very good (by report) it is for the cough: and being taken warme, it provoketh to vomit: put oile thereto, and it is ſingular againſt the poiſon of Ceruſe or white lead. A countrepoiſon alſo it is and a preſervative to ſuch as have eaten Henbane and Dwale, eſpecially taken with aſſes milke, as I have ſaid heretofore. Inſtilled into the ears, or powred into the fiſtulous ſores of the ſecret parts, it is thought to be excel- K
lent. Incorporat with the crums of ſoft bread, and reduced into the forme of a peſſarie, and ſo put up, it is ſingular for the infirmities of the naturall parts of women: and beeing applied accordingly, it taketh down all ſodaine ſwellings [occaſioned by windineſſe;] cureth diſlocations; and in one word, doth mitigat all pains. Thus much of Hydromel new made: for our moderne Phyſicians have utterly condemned the uſe of that which is kept untill it be ſtale. And this they generally hold, That it is not ſo harmeleſſe as water, nor ſo ſolid and powerfull in operation as wine. Howbeit, let it be long kept, it turneth into the nature of wine, and (as all writers doe accord) then is it moſt hurtfull to the ſtomacke, and contrarie to the ſinews.

As for Honied-wine, the beſt and moſt holeſome is alwaies that, which is made of the oldeſt wine, that is hard: and indeed with it, you ſhall have it to incorporat very eaſily; which it will ne- L
ver doe with any that is new, and ſweet: and being made of greene, harſh, or auſtere wine, it doth not fill and charge the ſtomacke, no more it doth being made of boiled honey; and engendreth leſſe ventoſities; which is an uſuall thing with honey. This honyed wine bringeth them to appetite of meat, who have loſt their ſtomacke. Taken actually cold, in many it looſeneth the belly; but being hot, it ſtaieth and bindeth the ſame. The honyed wine is very nutritive and breedeth good fleſh. Many have held out a long time freſh and luſtie in their old age, with the nouriſhment of honyed wine alone, without any other food: whereof wee have one notable example of *Pollio Romilus*, who beeing above a hundred yeares old, bare his age paſſing well: whereat the Emperour *Auguſtus* of famous memorie, marveiled much; and being upon a time lodged as a gueſt in his houſe, he demaunded of him, What means he uſed moſt ſo to maintaine that freſh M
vigor both of bodie and mind? unto whome *Pollio* anſwered, By uſing honyed wine within, and oile without. *Varro* ſaith, that the yellow jaundiſe was called a *Kings-diſeaſe, or a ſickneſſe for a King, becauſe it was cured ordinarily with this honyed wine, called Mulſe.

* *Regius morbus.*

As touching another kind of Honyed-wine, named Melitites, how it is made of Muſt, or new

wine

A wine and honey togither, I have declared sufficiently in my treatise of wines. But I suppose there hath been none of this sort confected these hundred yeares past and above, for that it was found to be a drinke which bred ventosities in the stomacke and other inward parts. Howbeit, the manner was in old time, to prescribe it for to bee given in agues, to make the bodie soluble; provided alwaies, that it had the due age: also to those who lay of the gout: to such likewise as had weake and feeble sinews: and to women who abstained altogither from meere wine.

Next after Honey, the treatise of Wax (which is correspondent to the nature of honey) by good order followeth. Concerning the originall working and framing thereof, the goodnesse, the severall kinds according to divers countries, I have written in convenient place. This is ge-
3 nerally observed, that all sorts of wax be emollitive, heating, and incarnative; but the newer and
B fresher that they are, the better they are thought to be. Wax taken inwardly in a supping or broth, is singular for the bloudie flix and exulceration of the guts: so be the very honey-combs given in a gruell made of frumentie, first parched and dried at the fire. Contrarie it is to the nature of milke: for take ten grains of wax, made in small pills of the bignesse of millet corns, in some convenient liquor, they will not suffer the milke to cruddle in the stomacke. If there bee a rising or swelling in the share, the present remedie is to sticke a plastre of white wax upon the groine. Moreover, to reckon up and descipher the sundrie uses that wax is put unto in matters of Physicke, as it is mixed with other things, it is no more possible for a Physician, than to particularize of other simples and of their holesome vertues, according as they enter into many compositions: which proceed all (as I have said) from the wit and artificiall invention of man: for wee
C never find, that Cerots, Cataplasms, Emollitives, Plastres, Collyries or Eye-salves, Antidotes or Preservative confections, were ever of our great mother dame Natures making; who indeed is the divine worke-mistresse of all things: these are the the devises of Apothecaries, nay they are rather tricks proceeding from avarice and covetousnesse. As for Nature, shee hath made nothing unperfect, her workes be absolute all and accomplished in their essence: ordained hath shee no compounds, unlesse it be verie few, wherein shee proceedeth upon good cause and reason, and goeth not by blind aime and doubtfull conjectures: as namely, when according to her rule and order, shee doth incorporat some things of a drie constitution and substance, with a liquor, that they may pierce and enter better within the pores of the bodie: or els when shee giveth consistence to liquid matters by some bodily substance, which may unite and knit them to-
D gether. To goe about for to compasse the vertues of every simple ingredient into these compositions curiously by scruples and grains, savoureth of impudencie rather than a worke grounded upon humane conjecture. For mine owne part, I have nothing to doe with these drugs and far-fet wares that come from India and Arabia: I meddle not (I say) with these medicinable spices brought out (as it were) of another world: These simples growing so farre off in such remote countries, please me not, neither doe I thinke them meet for to cure our maladies: they were never brought forth by Nature for us; no nor for them neither, where they grow: otherwise they were not such fooles (I trow) as to sell and passe them away as they doe. Buy them, and spare not, for sweet pomanders, perfumes, & delicat ointments: yee may buy them also (if you please) upon a superstitious devotion for the worship of gods; for that now we cannot sacrifice, pray, and serve
E God (forsooth) without Frankincense and Costus. And that our daintie ones and effeminat persons should be the more ashamed of themselves, I will the rather shew and proove, That we may both preserve and recover our health well enough without these exoticall and forein drugs: and that ech region is furnished sufficiently with home-physick of their owne. But now, since we have taken so much paines as to collect the medicinable vertues of guirland-flours, of pot-hearbs also, garden-woorts, and sallad hearbs, How may I for verie shame leave out the properties of corne and graine, serving for Physicke? And therefore in this place it shall bee well done, to discourse of them likewise.

Chap. xxv.

F ☞ *The medicinable vertues and properties of corne and graine.*

FIrst and foremost this is holden for certain, That they be the most ingenious and wisest creatures of all others, which live of corne. The grains of the fine blanchet wheat Siligo, being burnt, brought into powder, and applied with Amminien wine in manner of a liniment, do

reſtraine the flux of humors to the eyes. Alſo the corns of the ordinarie wheat Triticum, being parched or roſted upon a red hot yron, are a preſent remedie for thoſe who are ſcortched and findged with nipping cold. The meale of the ſaid wheat ſodden in vinegre, and applied as a cataplaſme, helpeth the contraction and ſhrinking up of the ſinews: but wheat brans, with oile of roſes, drie figgs, and ſebeſten ſodden togither, make a collution, the gargarizing wherewith, is good for the inflammation of the Tonſils or Amygdales, and to cure all the accidents of the throat. *Sextus Pompeius*, who in his daies was one of the principall peeres of high Spaine, and a ſonne behind him, who afterward was lord Pretour of Rome, ſitting upon a time before his barne-dores to ſee his corne winowed, was ſurpriſed ſodainly with a fit of the gout, and whether it were by chaunce, or in a rage for the extremitie of paine, thruſt his legs above the knees into the heape of wheat lying thereby: but finding his legs mightily dried hereby, and himſelfe wonderfully eaſed of his paine by that means, hee never uſed any other remedie afterwards, but ſo ſoone as he felt a fit of his gout comming, hee plunged his feet and legs into a heape of wheat. Certes wheat is ſuch a deſiccative, that it will draw and drie up the wine or any other liquor in a barrell which is buried within it. Moreover, the beſt experienced Chirurgians in the cure of ruptures, affirme, That there is nothing better, than to lay the chaffe of wheat or barley hot unto the grieved place; and to foment the ſame with a decoction wherein it was ſodden.

Vide Galen, lib. 1. de Naturalibus facultatibus.

As for the bearded wheat Far, there is a certaine worme breeding in it like to a moth or the grub that eateth wood, which is ſingular good to make rotten teeth to fall out of the head; for if the ſame be lapped within wax, and ſo put into the hole of the faultie tooth, it will drop out: or if the ſound teeth be but rubbed therewith, they will ſhed and fall forth of the head.

Touching the graine Olyra, we have ſaid alreadie that it is called alſo Arinca. The Ægyptians make thereof a certaine medicinable decoction or gruell, which they call Athara, paſſing good for young babes; yea and it ſerveth to bath and annoint elder folke withall.

Barly meale either raw or boiled, doth diſcuſſe and reſolve, aſſuage and ripen, all impoſtumes engendred either by way of gathering and collection of humors, or by ſome deflux and rheumaticke deſcent. The ſame otherwhiles is ſodden in honyed water, or els with dried figs: but for the pains of the liver, it had need to be boiled with Oxycrate, *i.* water and vinegre togither, or els with wine. But when the caſe ſtandeth ſo, that the tumour muſt bee partly diſſipated, and partly brought to maturation; then it is better that it be incorporat in vinegre, or in the lees of vinegre, or at leaſt waies in ſodden peares or ſodden quinces. Being tempered and medled with honey, it is very good for the biting of the cheeſlips or many-feet wormes, called Multipedes: but for the ſting of ſerpents, it is better to mix it with vinegre; as alſo to keepe ſores from feſtering and rankling: but in caſe it be needfull and requiſit to cleanſe them from ſuppurat matter therein gathered, then it would be applied with vinegre and water, with roſin alſo and gall-nuts added thereto. For inveterat and old ulcers, to bring them to maturation, it is laid too with roſin: for to ſoften hard tumors, it is uſed either with pigeons dung, or with drie figgs, or aſhes. Beeing applied with Poppie or Melilot, it is ſingular for the inflammation of the nerves, of the guts and ſides: alſo for the paines of mens privie parts: or when the fleſh is departed from the bone. Incorporat with pitch, and the urine of a boy not yet undergrowne nor fourteen yeers of age, it is a proper medicine for the ſwelling kernels named the Kings evill: with oile and Fenigreeke, it helpeth the tumors of the midriffe and precordiall parts: or in caſe the fever be buſie with the Patient, then it muſt be uſed with hony or old greaſe. But if thoſe ſwellings tend to maturation, then wheat meale is commonly more lenitive, and aſſuageth paine better. The ſame reduced into a liniment with the juice of Henbane, is good for the nerves; but with honey and vinegre, it taketh away the red pimples and ſpots appearing in the skin, called Lentils.

Spelt.

Touching * Zea, whereof is made the ordinarie frumentie as I have ſaid: the meale of it is counted better in operation than the other of barley, but that of the three-month corne is more moiſt and emollative. Tempered with red wine, and ſo applied warme, it is commended for the pricke of Scorpions: alſo for them that reach and ſpit up bloud: and all accidents happening to the throat and windpipes: but with goats ſewet or butter, it is good for the cough. The floure or meale of Fenigreeke, is the ſofteſt of all other: it healeth running ulcers, it ſcoureth dandruffe or skales in any part of the bodie, it appeaſeth and aſſuageth the pains of the ſtomacke, it cureth the maladies incident to the feet and paps, if it be ſodden with ſal-nitre and wine, and ſo applied accordingly.

The

A The meale of Yuraine or Darnell, doth cleanſe old ulcers & gangrenes more than any other. Tempered with raddiſh, ſalt, and vinegre, it cureth ring-wormes, tettars, ſhingles, and ſuch like: with Sulphur-vif or quicke brimſtome, it ſcoureth away the leproſie. Applied in a frontall to the forehead with Gooſe greaſe, it helpeth the head-ach. Boiled in wine with Pigeons dung & Line-ſeed, it digeſteth and bringeth to maturation the ſwelling kernels named the kings evill, and other biles which be long ere they gather to an head and doe ripen.

Of the ſundrie ſorts of Barley groats or groſſe meale called Polenta, I have ſaid ynough in my Treatiſe of corne, which did require alſo the diſcourſe of ſuch things as be made of corne. It differeth from Barly meale, in that it is torrefied or parched: in which regard it doth the ſtomack good. It bindeth and ſtaieth the flux of the bellie: it repreſſeth alſo and ſmiteth backe the flu-
B ſhing of humors, to the breeding of red and angrie tumors. It ſerveth for a liniment to the eyes, and eaſeth head-ach, if it be applied with *Mints, or ſome other cooling herbe. In like manner it cureth kibed heeles, and the wounds occaſioned by ſerpents: alſo it healeth burnes and skalds if it be laid too with wine: and in that ſort it keepeth them from bliſtering. If meale bee driven through a ſercer or boulter, and ſo reduced to flower, and afterwards made with dough or paſte, it is a great drawer of noiſome humors to the outward parts: which is the cauſe that being applied to ſuch places which looke dead and mortified, by reaſon of the bloud ſpread under the skin, it draweth out the ſame, ſo that the very linnen bands whet with they be lapped and rolled, become bloudie againe. But if wine cuit be joined therewith, the operation is more effectuall. Moreover, the ſaid flower is good to be laid unto the calloſities and cornes of the feet. For the fine flower of
C meale being ſodden with old oile and pitch, and applied ſo hot as the patient may abide it, doth wonderfully cure the ſwelling piles and all other greefes about the fundament. As touching the thick gruell or paps made with flower, it nouriſheth much, and cauſeth the bodie to ſeed well. The paſt made of meale, wherewith they uſe to glew Papyr, is ordinarily given warme to good effect, for the reaching and ſpitting of bloud.

*Cum Menta. rather *Melle*, i. honey, according to *Columella*: for Mints be hot.
